- **Standardized Identification:** While the log file header may label the second column as `Id`, it is functionally identical to the `thread_id` found in system tables (e.g., `mysql.general_log`) and the `Thread ID` in other server logs.
- **Immediate Logging:** Unlike the Binary Log, which logs at commit time, the General Query Log records queries immediately upon receipt.

Disabling the General Query Log for a Session

A user with the SUPER privilege can disable logging to the general query log for a connection by setting the SQL_LOG_OFF system variable to `1`. For example:

```
SET SESSION SQL_LOG_OFF=1;
```

Disabling the General Query Log for Specific Statements

In MariaDB 10.3.1 and later, it is possible to disable logging to the general query log for specific types of statements by setting the log_disabled_statements system variable. This option cannot be set dynamically. It can be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
log_output=FILE
general_log
general_log_file=queries.log
log_disabled_statements='slave,sp'
```

Rotating the General Query Log on Unix and Linux

Unix and Linux distributions offer the logrotate utility, which makes it very easy to rotate log files. See Rotating Logs on Unix and Linux for more information on how to use this utility to rotate the general query log.

MyISAM Log

The MyISAM log records all changes to MyISAM tables. It is not enabled by default. To enable it, start the server with the –log-isam option, for example:

```
--log-isam=myisam.log
```

The *isam* instead of *myisam* above is not a typo - it's a legacy from when the predecessor to the MyISAM format, called ISAM. The option can be used without specifying a filename, in which case the default, *myisam.log* is used.

To process the contents of the log file, use the myisamlog utility.

Rotating Logs on Unix and Linux

Unix and Linux distributions offer the logrotate utility, which makes it very easy to rotate log files. This page will describe how to configure log rotation for the error log, general query log, and the slow query log.

Configuring Locations and File Names of Logs

The first step is to configure the locations and file names of logs. To make the log rotation configuration easier, it can be best to put these logs in a dedicated log directory.

We will need to configure the following:

- The error log location and file name is configured with the log_error system variable.
- The general query log location and file name is configured with the general_log_file system variable.
- The slow query log location and file name is configured with the slow_query_log_file system variable.

If you want to enable the general query log and slow query log immediately, then you will also have to configure the following:

- The general query log is enabled with the general_log system variable.
- The slow query log is enabled with the slow_query_log system variable.

These options can be set in a server option group in an option file prior to starting up the server. For example, if we wanted to put our log files in `/var/log/mysql/`, then we could configure the following:

```
[mariadb]
...
log_error=/var/log/mysql/mariadb.err
general_log
general_log_file=/var/log/mysql/mariadb.log
slow_query_log
slow_query_log_file=/var/log/mysql/mariadb-slow.log
long_query_time=5
```

We will also need to create the relevant directory:

```
sudo mkdir /var/log/mysql/
sudo chown mysql:mysql /var/log/mysql/
sudo chmod 0770 /var/log/mysql/
```

If you are using SELinux, then you may also need to set the SELinux context for the directory. See SELinux: Setting the File Context for Log Files for more information. For example:

```
sudo semanage fcontext -a -t mysqld_log_t "/var/log/mysql(/.*)?"
sudo restorecon -Rv /var/log/mysql
```

After MariaDB is restarted, it will use the new log locations and file names.

Configuring Authentication for Logrotate

The logrotate utility needs to be able to authenticate with MariaDB in order to flush the log files.

The easiest way to allow the logrotate utility to authenticate with MariaDB is to configure the `root@localhost` user account.

Note

The `root@localhost` user account is configured to use unix_socket authentication by default

The `root@localhost` user account can be altered to use unix_socket authentication with the ALTER USER statement. For example:

```
ALTER USER 'root'@'localhost' IDENTIFIED VIA unix_socket;
```

<>

Configuring Logrotate

At this point, we can configure the logrotate utility to rotate the log files.

On many systems, the primary logrotate configuration file is located at the following path:

- `/etc/logrotate.conf`

And the logrotate configuration files for individual services are located in the following directory:

- `/etc/logrotate.d/`

We can create a logrotate configuration file for MariaDB by executing the following command in a shell:

```
$ sudo tee /etc/logrotate.d/mariadb <<EOF
/var/log/mysql/* {
        su mysql mysql
        missingok
        create 660 mysql mysql
        notifempty
        daily
        minsize 1M # only use with logrotate >= 3.7.4
        maxsize 100M # only use with logrotate >= 3.8.1
        rotate 30
        # dateext # only use if your logrotate version is compatible with below dateformat
        # dateformat .%Y-%m-%d-%H-%M-%S # only use with logrotate >= 3.9.2
        compress
        delaycompress
        sharedscripts
        olddir archive/
        createolddir 770 mysql mysql # only use with logrotate >= 3.8.9
    postrotate
        # just if mysqld is really running
        if test -x /usr/bin/mysqladmin && \
           /usr/bin/mysqladmin ping &>/dev/null
        then
           /usr/bin/mysqladmin --local flush-error-log \
              flush-engine-log flush-general-log flush-slow-log
        fi
    endscript
}
EOF
```

You may have to modify this configuration file to use it on your system, depending on the specific version of the logrotate utility that is installed. See the description of each configuration directive below to determine which logrotate versions support that configuration directive.

Each specific configuration directive does the following:

- `missingok`: This directive configures it to ignore missing files, rather than failing with an error.

- `create 660 mysql mysql`: This directive configures it to recreate the log files after log rotation with the specified permissions and owner.
- `notifempty`: This directive configures it to skip a log file during log rotation if it is empty.
- `daily`: This directive configures it to rotate each log file once per day.
- `minsize 1M`: This directive configures it to skip a log file during log rotation if it is smaller than 1 MB. This directive is only available with logrotate 3.7.4 and later.
- `maxsize 100M`: This directive configures it to rotate a log file more frequently than daily if it grows larger than 100 MB. This directive is only available with logrotate 3.8.1 and later.
- `rotate 30`: This directive configures it to keep 30 old copies of each log file.
- `dateext`: This directive configures it to use the date as an extension, rather than just a number. This directive is only available with logrotate 3.7.6 and later.
- `dateformat .%Y-%m-%d-%H-%M-%S`: This directive configures it to use this date format string (as defined by the format specification for strftime) for the date extension configured by the `dateext` directive. This directive is only available with logrotate 3.7.7 and later. Support for `%H` is only available with logrotate 3.9.0 and later. Support for `%M` and `%S` is only available with logrotate 3.9.2 and later.
- `compress`: This directive configures it to compress the log files with gzip.
- `delaycompress`: This directive configures it to delay compression of each log file until the next log rotation. If the log file is compressed at the same time that it is rotated, then there may be cases where a log file is being compressed while the MariaDB server is still writing to the log file. Delaying compression of a log file until the next log rotation can prevent race conditions such as these that can happen between the compression operation and the MariaDB server's log flush operation.
- `olddir archive/`: This directive configures it to archive the rotated log files in `/var/log/mysql/archive/`.
- `createolddir 770 mysql mysql`: This directive configures it to create the directory specified by the `olddir` directive with the specified permissions and owner, if the directory does not already exist. This directive is only available with logrotate 3.8.9 and later.
- `sharedscripts`: This directive configures it to run the `postrotate` script just once, rather than once for each rotated log file.
- `postrotate`: This directive configures it to execute a script after log rotation. This particular script executes the mariadb-admin utility, which executes the FLUSH statement, which tells the MariaDB server to flush its various log files. When MariaDB server flushes a log file, it closes its existing file handle and reopens a new one. This ensure that MariaDB server does not continue writing to a log file after it has been rotated. This is an important component of the log rotation process.

If our system does not have logrotate 3.8.9 or later, which is needed to support the `createolddir` directive, then we will also need to create the relevant directory specified by the `olddir` directive:

```
sudo mkdir /var/log/mysql/archive/
sudo chown mysql:mysql /var/log/mysql/archive/
sudo chmod 0770 /var/log/mysql/archive/
```

Testing Log Rotation

We can test log rotation by executing the logrotate utility with the `--force` option. For example:

```
sudo logrotate --force /etc/logrotate.d/mariadb
```

Keep in mind that under normal operation, the logrotate utility may skip a log file during log rotation if the utility does not believe that the log file needs to be rotated yet. For example:

- If you set the `notifempty` directive mentioned above, then it will be configured to skip a log file during log rotation if the log file is empty.

- If you set the `daily` directive mentioned above, then it will be configured to only rotate each log file once per day.
- If you set the `minsize 1M` directive mentioned above, then it will be configured to skip a log file during log rotation if the log file size is smaller than 1 MB.

However, when running tests with the `--force` option, the logrotate utility does not take these options into consideration.

After a few tests, we can see that the log rotation is indeed working:

```
$ sudo ls -l /var/log/mysql/archive/
total 48
-rw-rw---- 1 mysql mysql  440 Mar 31 15:31 mariadb.err.1
-rw-rw---- 1 mysql mysql  138 Mar 31 15:30 mariadb.err.2.gz
-rw-rw---- 1 mysql mysql  145 Mar 31 15:28 mariadb.err.3.gz
-rw-rw---- 1 mysql mysql 1007 Mar 31 15:27 mariadb.err.4.gz
-rw-rw---- 1 mysql mysql 1437 Mar 31 15:32 mariadb.log.1
-rw-rw---- 1 mysql mysql  429 Mar 31 15:31 mariadb.log.2.gz
-rw-rw---- 1 mysql mysql  439 Mar 31 15:28 mariadb.log.3.gz
-rw-rw---- 1 mysql mysql  370 Mar 31 15:27 mariadb.log.4.gz
-rw-rw---- 1 mysql mysql 3915 Mar 31 15:32 mariadb-slow.log.1
-rw-rw---- 1 mysql mysql  554 Mar 31 15:31 mariadb-slow.log.2.gz
-rw-rw---- 1 mysql mysql  569 Mar 31 15:28 mariadb-slow.log.3.gz
-rw-rw---- 1 mysql mysql  487 Mar 31 15:27 mariadb-slow.log.4.gz
```

Logrotate in Ansible

Let's see an example of how to configure logrotate in Ansible.

First, we'll create a couple of tasks in our playbook:

```
- name: Create mariadb_logrotate_old_dir
  file:
    path: "{{ mariadb_logrotate_old_dir }}"
    owner: mysql
    group: mysql
    mode: '770'
    state: directory

- name: Configure logrotate
  template:
    src: "../templates/logrotate.j2"
    dest: "/etc/logrotate.d/mysql"
```

The first task creates a directory to store the old, compressed logs, and set proper permissions.

The second task uploads logrotate configuration file into the proper directory, and calls it `mysql`. As you can see the original name is different, and it ends with the `.j2` extension, because it is a Jinja 2 template.

The file will look like the following:

```
{{ mariadb_log_dir }}/* {
        su mysql mysql
        missingok
        create 660 mysql mysql
        notifempty
        daily
        minsize 1M {{ mariadb_logrotate_min_size }}
        maxsize 100M {{ mariadb_logrotate_max_size }}
        rotate {{ mariadb_logrotate_old_dir }}
        dateformat .%Y-%m-%d-%H-%M-%S # only use with logrotate >= 3.9.2
        compress
        delaycompress
        sharedscripts
        olddir archive/
        createolddir 770 mysql mysql # only use with logrotate >= 3.8.9
    postrotate
        # just if mysqld is really running
        if test -x /usr/bin/mysqladmin && \
           /usr/bin/mysqladmin ping &>/dev/null
        then
           /usr/bin/mysqladmin --local flush-error-log \
              flush-engine-log flush-general-log flush-slow-log
        fi
    endscript
}
```

The file is very similar to the file shown above, which is obvious because we're still uploading a logrotate configuration file. Ansible is just a tool we've chosen to do this.

However, both in the tasks and in the template, we used some variables. This allows to use different paths and rotation parameters for different hosts, or host groups.

If we have a group host called `mariadb` that contains the default configuration for all our MariaDB servers, we can define these variables in a file called `group_vars/mariadb.yml`:

```
# MariaDB writes its logs here
mariadb_log_dir: /var/lib/mysql/logs

# logrotate configuration

mariadb_logrotate_min_size: 500M
mariadb_logrotate_max_size: 1G
mariadb_logrotate_old_files: 7
mariadb_logrotate_old_dir: /var/mysql/old-logs
```

After setting up logrotate in Ansible, you may want to deploy it to a non-production server and test it manually as explained above. Once you're sure that it works fine on one server, you can be confident in the new Ansible tasks and deploy them on all servers.

For more information on how to use Ansible to automate MariaDB configuration, see Ansible and MariaDB.

Slow Query Log

See Slow Query Log Overview.

Complete Slow Query Log Overview guide for MariaDB. Complete reference documentation for implementation, configuration, and usage for production use.

See EXPLAIN in the Slow Query Log.

Describes how to configure MariaDB to automatically write the `EXPLAIN` plan for slow queries to the log using the `log_slow_verbosity` system variable.

See log_slow_always_query_time System Variable.

Documentation for the `log_slow_always_query_time` variable, which forces queries executed by a specific function or user to be logged regardless of their execution time.

This page is licensed: CC BY-SA / Gnu FDL

Slow Query Log Overview

The slow query log is a record of SQL queries that took a long time to perform. The log also provides the number of rows affected by slow queries.

> **Note:**
>
> If your queries contain passwords, the slow query log can contain sensitive information, too. Ensure to store the log files in a safe location.
>
> While MariaDB natively encrypts Binary Logs and Data files, it does not provide built-in encryption for the Slow Query or General Query logs. To secure these, administrators should either log to Internal Tables (combined with Data-at-Rest encryption) or utilize OS-level filesystem encryption.

Enabling the Slow Query Log

The slow query log is disabled by default. To enable it, set log_slow_query to `1`, using one of the following methods.

This turns on slow query logging immediately, but only until the next server restart:

```
SET GLOBAL slow_query_log=1;
```

To make this permanent, configure it in a server option group in an option file, then restart the server:

```
[mariadb]
slow_query_log
```

To verify that slow query logging is enabled, and to see which log file is used, issue this statement:

```
SHOW GLOBAL VARIABLES LIKE 'slow_query_log%';
+---------------------+----------------------------------------------+
| Variable_name       | Value                                        |
+---------------------+----------------------------------------------+
| slow_query_log      | ON                                           |
| slow_query_log_file | c525d37c-b2ff-4543-b06f-87012d142d44-slow.log |
+---------------------+----------------------------------------------+
```

Configuring the Filename

By default, the slow query log is written to `${hostname}-slow.log` (for instance, `c525d37c-b2ff-4543-b06f-87012d142d44-slow.log`), and stored in the datadir directory. However, this can be changed.

Configure the slow query log filename by setting the slow_query_log_file system variable (or, from MariaDB 10.11, log_slow_query_file). It can be changed dynamically with SET GLOBAL:

```
SET GLOBAL slow_query_log_file='mariadb-slow.log';
```

To make this permanent, configure it in a server option group in an option file, then restart the server:

```
[mariadb]
slow_query_log
slow_query_log_file=mariadb-slow.log
```

Setting a relative path, or just the filename, puts the log file in the datadir directory. You can put it somewhere else by using an absolute path:

```
[mariadb]
slow_query_log
slow_query_log_file=/var/log/mysql/mariadb-slow.log
```

Another way to configure the slow query log filename is to set the log-basename option, which configures MariaDB to use a common prefix for all log files (e.g. slow query log, general query log, error log, binary logs, etc.). The slow query log filename will be built by adding `-slow.log` to this prefix. This option cannot be set dynamically. It can be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
log-basename=mariadb
slow_query_log
```

> **Note:**
>
> If you configure all log file basenames using –log-basename, you cannot use an absolute path – the log file name is always relative to the datadir directory.

Choosing the Output Destination

The slow query log can either be written to a file or to the slow_log table in the mysql database. To choose the slow query log output destination, set the log_output system variable.

To verify what logging method is used, issue this query:

```
SHOW GLOBAL VARIABLES LIKE 'log_output';
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| log_output    | TABLE |
+---------------+-------+
```

File Logging

File logging is the default. You can configure it explicitly by setting the log_output system variable to `FILE`. (For instance, to switch back from the table logging method.)

Enable file logging until server restart:

```
SET GLOBAL log_output='FILE';
```

To make this permanent, configure it in a server option group in an option file, then restart the server:

```
[mariadb]
log_output=FILE
slow_query_log
slow_query_log_file=slow-queries.log
```

Parsing Specification (File Format)

When logging to a file, the Slow Query Log uses a multi-line format. Parsers must identify the start of a record and correctly separate the header metadata from the SQL query payload.

Record Start Indicator: Every log entry begins with the literal string: `# User@Host:`

Header Specification: The metadata section consists of several lines starting with a hash (`#`). These fields should be mapped as follows:

Line	Component Template	Key Fields
1	`# User@Host: {User}[{User}] @ {Host} [{IP}]`	`User` , `Host` , `IP`
2	`# Thread_id: {ID} Schema: {DB} QC_hit: {No/Yes}`	`Thread ID` , `Schema` , `QC_hit`
3	`# Query_time: {Float} Lock_time: {Float} ...`	`Query_time` , `Lock_time` , `Rows_sent` , `Rows_examined`

SQL Payload: The lines following the `#` headers contain the raw SQL statement.

- **Note:** The SQL query can span multiple lines.
- **Termination:** The record ends when the next `# User@Host:` indicator is encountered or the file ends.

Parsing Example for Tool Developers

A standard parser regex should look for the following sequence:

1. **Start:** `^# User@Host: .*`
2. **Metadata Capture:** Capture all lines starting with `#` until a line without a `#` is reached.
3. **Query Capture:** Everything from the first non-`#` line until the next record start.

Table Logging

The slow query log can either be written to the slow_log table in the mysql database by setting the log_output system variable to `TABLE` . It can be changed dynamically with SET GLOBAL. For example:

```
SET GLOBAL log_output='TABLE';
```

To make this permanent, configure it in a server option group in an option file, then restart the server:

```
[mariadb]
log_output=TABLE
slow_query_log
```

Display the slow query log by issuing this statement:

```
SELECT * FROM mysql.slow_log\G
...
*************************** 2. row ***************************
    start_time: 2014-11-11 07:56:28.721519
     user_host: root[root] @ localhost []
    query_time: 00:00:12.000215
     lock_time: 00:00:00.000000
     rows_sent: 1
 rows_examined: 0
            db: test
last_insert_id: 0
     insert_id: 0
     server_id: 1
      sql_text: SELECT SLEEP(12)
     thread_id: 74
...
```

See Writing logs into tables for more information.

Disabling the Log for a Session

Any user can disable logging for a connection by setting the slow_query_log system variable (or, from MariaDB 10.11, log_slow_query) to `0` :

```
SET SESSION slow_query_log=0;
```

Disabling the Log for Specific Statements

You can disable logging to the slow query log for specific types of statements by setting the log_slow_disabled_statements system variable. This option can only be set permanently, in a server option group in an option file prior, then restarting the server:

```
[mariadb]
log_output=FILE
slow_query_log
log_slow_disabled_statements='admin,call,slave,sp'
```

Configuring the Slow Query Log Time

The time that defines a slow query can be configured by setting the long_query_time system variable (or, from MariaDB 10.11, log_slow_query_time). It uses a units of seconds, with an optional milliseconds component. The default value is `10`. It can be changed dynamically with SET GLOBAL:

```
SET GLOBAL long_query_time=5.0;
```

To make this permanent, configure it in a server option group in an option file, then restart the server:

```
[mariadb]
slow_query_log
long_query_time=5.0
```

To verify this works as intended, you can force a “slow” query to happen. By default, MariaDB won’t log a query unless it takes longer than a certain amount of time (10 seconds by default). Check your settings first (output abbreviated):

```
SHOW GLOBAL VARIABLES LIKE 'slow_query_log';
SHOW GLOBAL VARIABLES LIKE 'log_output';
SHOW GLOBAL VARIABLES LIKE 'long_query_time';
+----------------+-------+
| Variable_name  | Value |
+----------------+-------+
| slow_query_log | ON    |
+----------------+-------+
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| log_output    | TABLE |
+---------------+-------+
+-----------------+-----------+
| Variable_name   | Value     |
+-----------------+-----------+
| long_query_time | 10.000000 |
+-----------------+-----------+
```

Run a sleep statement longer than the threshold of 10 seconds, then inspect the slow query log:

```
SELECT SLEEP(11);
+-----------+
| SLEEP(11) |
+-----------+
|         0 |
+-----------+
1 row in set (11.074 sec)

MariaDB [(none)]> SELECT * FROM mysql.slow_log \G
*************************** 1. row ***************************
    start_time: 2026-02-06 18:38:23.071314
     user_host: stefanhinz[stefanhinz] @ localhost []
    query_time: 00:00:11.073655
     lock_time: 00:00:00.000000
     rows_sent: 1
 rows_examined: 0
            db:
last_insert_id: 0
     insert_id: 0
     server_id: 1
      sql_text: SELECT SLEEP(11)
     thread_id: 7
 rows_affected: 0
```

If you use FILE logging, check the contents of the log file in your terminal.

Logging Queries That Don't Use Indexes

It can be beneficial to log queries that don't use indexes to the slow query log, since such queries can usually be optimized, either by adding an index or by doing a slight rewrite. The slow query log can be configured to log queries that don't use indexes regardless of their execution time, by adding the option `not_using_index` to log_slow_filter, or by setting the log_queries_not_using_indexes system variable to `1`. It can be changed dynamically with SET GLOBAL:

```
SET @@log_slow_filter=concat(@@log_slow_filter,",not_using_index");
SET GLOBAL log_queries_not_using_indexes=ON;
```

To make this permanent, configure it in a server option group in an option file, then restart the server:

```
[mariadb]
log_output=FILE
slow_query_log
slow_query_log_file=slow-queries.log
long_query_time=5.0
log_queries_not_using_indexes=ON
```

As a significant number of queries can run quickly even without indexes, you can use the min_examined_row_limit system variable (or, from MariaDB 10.11, log_slow_min_examined_row_limit) with log_queries_not_using_indexes, to limit the logged queries to those having a material performance impact on the server.

Excluding Queries That Examine Fewer Than a Minimum Row Limit

It can be beneficial to exclude queries that examine fewer than a minimum number of rows from the log. This can be done by setting the min_examined_row_limit system variable, or, from MariaDB 10.11, log_slow_min_examined_row_limit. It can be changed dynamically with SET GLOBAL:

```
SET GLOBAL min_examined_row_limit=100000;
```

To make this permanent, configure it in a server option group in an option file, then restart the server:

```
[mariadb]
log_output=FILE
slow_query_log
slow_query_log_file=slow-queries.log
long_query_time=5.0
min_examined_row_limit=100000
```

Logging Slow Administrative Statements

By default, the slow query log logs administrative statements. To disable that, remove `admin` from the log_slow_filter system variable. Alternatively, set the log_slow_admin_statements system variable to `OFF`. The slow query log considers the following statements administrative: ALTER TABLE, ANALYZE TABLE, CHECK TABLE, CREATE INDEX, DROP INDEX, OPTIMIZE TABLE, and REPAIR TABLE. This also includes ALTER SEQUENCE statements.

You can dynamically enable this feature using a SET GLOBAL statement and setting it for just the current connection with `LOCAL`. Some examples:

```
SET SESSION log_slow_filter=replace(@@log_slow_filter,"admin","");
SET GLOBAL log_slow_admin_statements=ON;
```

To make this permanent, configure it in a server option group in an option file, then restart the server:

```
[mariadb]
...
log_output=FILE
slow_query_log
slow_query_log_file=slow-queries.log
long_query_time=5.0
log_slow_admin_statements=ON
```

Enabling the Slow Query Log for Specific Criteria

It is possible to enable logging to the slow query log for queries that meet specific criteria by configuring the log_slow_filter system variable. It can be changed dynamically with SET GLOBAL:

```
SET GLOBAL log_slow_filter='filesort,filesort_on_disk,tmp_table,tmp_table_on_disk';
```

To make this permanent, configure it in a server option group in an option file, then restart the server:

```
[mariadb]
log_output=FILE
slow_query_log
slow_query_log_file=slow-queries.log
long_query_time=5.0
log_slow_filter=filesort,filesort_on_disk,tmp_table,tmp_table_on_disk
```

You can find all options for log_slow_filter at log_slow_filter system variable or at Slow Query Log Extended Statistics.

Throttling the Slow Query Log

The slow query log can create a lot of I/O[25], so it can be beneficial to throttle it in some cases. The slow query log can be throttled by configuring the log_slow_rate_limit system variable. It can be changed dynamically with SET GLOBAL:

```
SET GLOBAL log_slow_rate_limit=5;
```

To make this permanent, configure it in a server option group in an option file, then restart the server:

```
[mariadb]
log_output=FILE
slow_query_log
slow_query_log_file=slow-queries.log
long_query_time=5.0
log_slow_rate_limit=5
```

Configuring the Verbosity

There are a few optional pieces of information that can be included in the slow query log for each query. This optional information can be included by configuring the log_slow_verbosity system variable. It can be changed dynamically with SET GLOBAL:

```
SET GLOBAL log_slow_verbosity='full';
```

To make this permanent, configure it in a server option group in an option file, then restart the server:

```
[mariadb]
...
log_output=FILE
slow_query_log
slow_query_log_file=slow-queries.log
long_query_time=5.0
log_slow_verbosity=query_plan,explain,engine
```

It is possible to have EXPLAIN output printed in the slow query log.

Viewing the Slow Query Log

Slow query logs written to file can be viewed with any text editor, or you can use the mariadb-dumpslow tool, to ease the process by summarizing the information.

Queries that you find in the log are key queries to try to optimize by constructing a more efficient query or by making better use of indexes.

For queries that appear in the log that cannot be optimized in the above ways, perhaps because they are simply very large selects, due to slow hardware, or very high lock/cpu/io contention, using shard/clustering/load balancing solutions, better hardware, or stats tables may help to improve these queries.

Slow query logs written to table can be viewed by querying the slow_log table.

Variables Related to the Slow Query Log

- slow_query_log - enable/disable the slow query log. Renamed to log_slow_query from MariaDB 10.11.
- log_output - how the output will be written.
- log_slow_admin_statements. Whether to log `OPTIMIZE`, `ANALYZE`, `ALTER`, and other administrative statements to the slow log. Deprecated from MariaDB 11.0, use log_slow_filter without admin.
- slow_query_log_file - name of the slow query log file. Renamed to log_slow_query_file_name from MariaDB 10.11.0.
- long_query_time - time in seconds/microseconds defining a slow query. Renamed to log_slow_query_time from MariaDB 10.11.0.
- log_queries_not_using_indexes - whether or not to log queries that don't use indexes.
- log_slow_admin_statements - whether or not to log certain admin statements.
- log_slow_disabled_statements - types of statements that should not be logged in the slow query log.
- min_examined_row_limit - minimum rows a query must examine to be slow. Renamed to log_slow_min_examined_row_limit from MariaDB 10.11.0.

- log_slow_rate_limit - permits a fraction of slow queries to be logged.
- log_slow_verbosity - amount of detail in the log.
- log_slow_filter - limit which queries to log.
- log_slow_slave_statements - log slow statements executed by replica thread to the slow log if it is open.

Rotating the Slow Query Log on Unix and Linux

Unix and Linux distributions offer the logrotate utility, which makes it easy to rotate log files. See Rotating Logs on Unix and Linux for more information on how to use this utility to rotate the slow query log.

This page is licensed: CC BY-SA / Gnu FDL

EXPLAIN in the Slow Query Log

Additional Columns in MariaDB 10.1 and Later

Starting from MariaDB 10.1.0, the `EXPLAIN` output in the slow query log includes two additional columns: `r_rows` and `r_filtered`

When a user manually executes the standard `EXPLAIN` statement, these columns are not displayed. Instead, they come from the `ANALYZE` statement, which runs the query and returns actual runtime statistics.

MariaDB uses `ANALYZE` statement internally to generate the `EXPLAIN` output when a query is stored in the slow query log. As a result, the slow query log may contain both estimated and actual execution statistics.

For more information about `r_rows` and `r_filtered` columns, see the ANALYZE Statement page.

Switching it On

EXPLAIN output can be switched on by specifying the `explain` keyword in the log_slow_verbosity system variable. Alternatively, you can set with the `log-slow-verbosity` command line argument.

```
[mysqld]
log-slow-verbosity=query_plan,explain
```

EXPLAIN output will only be recorded if the slow query log is written to a file (and not to a table - see Writing logs into tables). This limitation also applies to other extended statistics that are written into the slow query log.

What it Looks Like

When explain recording is on, slow query log entries look like this:

```
# User@Host: user[user] @ test.domain.com [10.6.184.141]
# Thread_id: 75816 Schema: db QC_hit: No
# Query_time: 420.906319 Lock_time: 0.086885 Rows_sent: 0 Rows_examined: 9734191
# Rows_affected: 0
#
# explain: id select_type table type possible_keys key key_len ref rows r_rows filtered r_filtered Extra
# explain: 1 SIMPLE tab ALL a_timestamp_indx NULL NULL NULL 9330481 9734191.00 100.00 55.55 Using where
#
SET timestamp=1535157447;
delete from tab where a_timestamp < (unix_timestamp(now())-14400)*1000000;
```

`EXPLAIN` lines start with `explain:`.

log_slow_always_query_time System Variable

- Description: Queries slower than log_slow_always_query_time are not affected by log_slow_rate_limit or log_slow_min_examined_row_limit. Query will be logged to the slow query log if the execution time of the query is longer than log_slow_query_time and log_slow_always_query_time. The argument will be treated as a decimal value with microsecond precision.
- Command line: `--log-slow-always-query-time=num`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric (double)`
- Default Value: `31536000.000000`
- Range: `0` to `31536000`
- Introduced: MariaDB 11.7

This page is licensed: CC BY-SA / Gnu FDL

SQL Error Log Plugin

The `SQL_ERROR_LOG` plugin collects errors sent to clients in a log file defined by sql_error_log_filename, so that they can later be analyzed. The log file can be rotated if sql_error_log_rotate is set.

Errors are logged as they happen and an error will be logged even if it was handled by a condition handler and was never technically *sent* to the client.

From MariaDB 10.11.5 warnings can also be logged if sql_error_log_warnings is enabled.

Comments are also logged, which can make the log easier to search. But this is only possible if the client does not strip the comments away. For example, the mariadb command-line client only leaves comments when started with the –comments option.

Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing INSTALL SONAME or INSTALL PLUGIN. For example:

```
INSTALL SONAME 'sql_errlog';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the –plugin-load or the –plugin-load-add options. This can be specified as a command-line argument to mariadbd or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
plugin_load_add = sql_errlog
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN. For example:

```
UNINSTALL SONAME 'sql_errlog';
```

If you installed the plugin by providing the –plugin-load or the –plugin-load-add options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time

the server is restarted.

Logging

The log format until MariaDB 10.10 is:

```
Time User Error_code: Error_message : Query
```

Starting from MariaDB 10.11, the format is:

```
Time User Type Error_code: Error_message : Query
```

Starting from MariaDB 10.6.17, MariaDB 10.11.7, MariaDB 11.0.5, MariaDB 11.1.4, MariaDB 11.2.3, MariaDB 11.3.2, and MariaDB 11.4.1, when the sql_error_log_with_db_and_thread_info variable is enabled, the log also contains thread id and database name. If there is no database, `NULL` will be displayed.

```
Time Thread_id User Database_name Type Error_code: Error_message : Query
```

Each separated by a space or : as above

Option	Description	Version
Time	Time (YYYY-MM-DD hh-mm-ss)	5.5.22
Thread Id	Thread Id of current thread	10.6.17
User	privilege_user [login_user_name] @ hostname [ip]	5.5.22
Database name	Name of the currently selected database	10.6.17
Type	ERROR or WARNING	10.11.6
Error_code	OS error, MariaDB storage engine code (120-199) or MariaDB internal error code (1000-)	5.5.22
Query	Query text	5.5.22

Formal Specification

The SQL Error Log Plugin collects errors sent to clients. Depending on the version and configuration (`sql_error_log_with_db_and_thread_info`), the log follows a positional space-delimited format.

Modern Template (MariaDB 11.4+ with Full Info): `Time Thread_id User Database_name Type Error_code: Error_message : Query`

Time	**`YYYY-MM-DD hh-mm-ss`**	**Timestamp of the error.**
Thread_id	`Unsigned Integer`	Standardized: Thread ID. Matches the `Thread ID` in all other server logs.
User	`String`	The login user and client host/IP.
Database_name	`String`	The selected database or `NULL`.
Type	`ERROR` or `WARNING`	Severity level of the message.
Error_code	`Integer`	MariaDB or OS error code.
Query	`String`	The literal SQL query text.

Example of Logs

```
2023-10-31 15:54:37 root[root] @ localhost [] ERROR 1146: Table 'test.t_doesnt_exist' doesn't exist :
select * from t_doesnt_exist
2023-10-31 15:54:37 root[root] @ localhost [] ERROR 1064: You have an error in your SQL syntax; check the
manual that corresponds to your MariaDB server version for the right syntax to use near
'syntax_error_query' at line 1 : syntax_error_query
2023-10-31 15:54:37 root[root] @ localhost [] ERROR 1146: Table 'test.temptab' doesn't exist : SELECT `c`
FROM `temptab`
2023-11-01 11:31:15 [monty] @ storm [192.168.0.12] ERROR 1051: Unknown table 'test.t1' : drop table t1
```

With sql_error_log_with_db_and_thread_info enabled (database `test` and thread id `4`):

```
2023-10-31 15:54:37 4 root[root] @ localhost [] `test` ERROR 1146: Table 'test.t_doesnt_exist' doesn't
exist : select * from t_doesnt_exist
```

Example Usage

```
install plugin SQL_ERROR_LOG soname 'sql_errlog';
Query OK, 0 rows affected (0.00 sec)

USE test;

SET sql_mode='STRICT_ALL_TABLES,NO_ENGINE_SUBSTITUTION';
Query OK, 0 rows affected (0.00 sec)

CREATE TABLE foo2 (id INT) ENGINE=WHOOPSIE;
ERROR 1286 (42000): Unknown storage engine 'WHOOPSIE'
\! cat data/sql_errors.log
2013-03-19  9:38:40 msandbox[msandbox] @ localhost [] ERROR 1286: Unknown storage engine 'WHOOPSIE' :
CREATE TABLE foo2 (id int) ENGINE=WHOOPSIE
```

Versions

Version	Status	Introduced
1.1	Stable	MariaDB 10.6.17, MariaDB 10.11.7, MariaDB 11.0.5, MariaDB 11.1.4, MariaDB 11.2.3
1.0	Stable	MariaDB 10.1.13
1.0	Gamma	MariaDB 10.0.10
1.0	Alpha	MariaDB 5.5.22

Transaction Coordinator Log

See Transaction Coordinator Log Overview.

Explains the purpose of the Transaction Coordinator (TC) log (`tc.log`), which maintains consistency for XA transactions that affect multiple storage engines, and how to configure it.

See Heuristic Recovery with the Transaction Coordinator Log.

Describes the process of heuristic recovery using the TC log to resolve “in-doubt” transactions that may occur after a server crash during a 2-phase commit.

This page is licensed: CC BY-SA / Gnu FDL

Transaction Coordinator Log Overview

The transaction coordinator log (tc_log) is used to coordinate transactions that affect multiple XA-capable storage engines. If you have two or more XA-capable storage engines enabled, then a transaction coordinator log must be available.

Types of Transaction Coordinator Logs

There are currently two implementations of the transaction coordinator log:

- Binary log-based transaction coordinator log
- Memory-mapped file-based transaction coordinator log

If the binary log is enabled on a server, then the server will use the binary log-based transaction coordinator log. Otherwise, it will use the memory-mapped file-based transaction coordinator log.

Binary Log-Based Transaction Coordinator Log

This transaction coordinator uses the binary log, which is enabled by the log_bin server option.

Memory-Mapped File-Based Transaction Coordinator Log

This transaction coordinator uses the memory-mapped file defined by the –log-tc server option. The size is defined by the log_tc_size system variable.

Some facts about this log:

- The log consists of a memory-mapped file that is divided into pages of 8KB size.
- The usable size of the first page is smaller because of the log header. There is a PAGE control structure for each page.
- Each page (or rather its PAGE control structure) can be in one of the three states - active, syncing, pool.
- There could be only one page in the active or syncing state, but many in the pool state - pool is a fifo queue.
- The usual lifecycle of a page is pool->active->syncing->pool.
- The “active” page is a page where new xid’s are logged.
- The page stays active as long as the syncing slot is taken.
- The “syncing” page is being synced to disk. no new xid can be added to it.
- When the syncing is done the page is moved to a pool and an active page becomes “syncing”.

The result of such an architecture is a natural “commit grouping” - If commits are coming faster than the system can sync, they do not stall. Instead, all commits that came since the last sync are logged to the same “active” page, and they all are synced with the next - one - sync. Thus, thought individual commits are delayed, throughput is not decreasing.

When an xid is added to an active page, the thread of this xid waits for a page’s condition until the page is synced. When a syncing slot becomes vacant one of these waiters is awakened to take care of syncing. It syncs the page and signals all waiters that the page is synced. The waiters are counted, and a page may never become active

again until waiters==0, which means that is all waiters from the previous sync have noticed that the sync was completed.

Note that a page becomes “dirty” and has to be synced only when a new xid is added into it. Removing a xid from a page does not make it dirty - we don’t sync xid removals to disk.

Monitoring the Memory-Mapped File-Based Transaction Coordinator Log

The memory-mapped transaction coordinator log can be monitored with the following status variables:

- Tc_log_max_pages_used
- Tc_log_page_size
- Tc_log_page_waits

Heuristic Recovery with the Transaction Coordinator Log

One of the main purposes of the transaction coordinator log is in crash recovery. See Heuristic Recovery with the Transaction Coordinator Log for more information about that.

Known Issues

You must enable exactly N storage engines

Prior to MariaDB 10.1.10, if you were using the memory-mapped file-based transaction coordinator log, and then if the server crashed and you changed the number of XA-capable storage engines that it loaded, then you could see errors like the following:

```
2018-11-30 23:08:49 140046048638848 [Note] Recovering after a crash using tc.log
2018-11-30 23:08:49 140046048638848 [ERROR] Recovery failed! You must enable exactly 3 storage engines
that support two-phase commit protocol
2018-11-30 23:08:49 140046048638848 [ERROR] Crash recovery failed. Either correct the problem (if it's,
for example, out of memory error) and restart, or delete tc log and start mysqld with --tc-heuristic-
recover={commit|rollback}
2018-11-30 23:08:49 140046048638848 [ERROR] Can't init tc log
2018-11-30 23:08:49 140046048638848 [ERROR] Aborting
```

To recover from this error, delete the file defined by the –log-tc server option, and then restart the server with the –tc-heuristic-recover option set.

See MDEV-9214 for more information.

Bad magic header in tc log

If you are using the memory-mapped file-based transaction coordinator log, then it is possible to see errors like the following:

```
2018-09-19  4:29:31 0 [Note] Recovering after a crash using tc.log
2018-09-19  4:29:31 0 [ERROR] Bad magic header in tc log
2018-09-19  4:29:31 0 [ERROR] Crash recovery failed. Either correct the problem (if it's, for example,
out of memory error) and restart, or delete tc log and start mysqld with --tc-heuristic-recover=
{commit|rollback}
2018-09-19  4:29:31 0 [ERROR] Can't init tc log
2018-09-19  4:29:31 0 [ERROR] Aborting
```

This means that the header of the memory-mapped file-based transaction coordinator log is corrupt. To recover from this error, delete the file defined by the –log-tc server option, and then restart the server with the –tc-heuristic-recover option set.

This issue is known to occur when using docker. In that case, the problem may be caused by using a MariaDB container version with a data directory from a different MariaDB or MySQL version. Therefore, some potential fixes

are:

- Pinning the docker instance to a specific MariaDB version in the docker compose file, so that it consistently uses the same version.
- Running mariadb-upgrade to ensure that the data directory is upgraded to match the server version.

See this docker issue for more information.

MariaDB Galera Cluster

MariaDB Galera Cluster builds include a built-in plugin called `wsrep`. Prior to MariaDB 10.4.3, this plugin was internally considered an XA-capable storage engine. Consequently, these MariaDB Galera Cluster builds have multiple XA-capable storage engines by default, even if the only "real" storage engine that supports external XA transactions enabled on these builds by default is InnoDB. Therefore, when using one these builds MariaDB would be forced to use a transaction coordinator log by default, which could have performance implications.

For example, MDEV-16509 describes performance problems where MariaDB Galera Cluster actually performs better when the binary log is enabled. It is possible that this is caused by the fact that MariaDB is forced to use the memory-mapped file-based transaction coordinator log in this case, which may not perform as well.

This became a bigger issue in MariaDB 10.1 when the MySQL-wsrep patch that powers MariaDB Galera Cluster was enabled on most MariaDB builds on Linux by default. Consequently, this built-in `wsrep` plugin would exist on those MariaDB builds on Linux by default. Therefore, MariaDB users might pay a performance penalty, even if they never actually intended to use the MariaDB Galera Cluster features included in MariaDB 10.1.

In MariaDB 10.4.3 and later, the built-in `wsrep` plugin has been changed to a replication plugin. Therefore, it is no longer considered an XA-capable storage engine, so it no longer forces MariaDB to use a transaction coordinator log by default.

See MDEV-16442 for more information.

This page is licensed: CC BY-SA / Gnu FDL

Heuristic Recovery with the Transaction Coordinator Log

The transaction coordinator log (tc_log) is used to coordinate transactions that affect multiple XA-capable storage engines. One of the main purposes of this log is in crash recovery.

Modes of Crash Recovery

There are two modes of crash recovery:

- Automatic crash recovery.
- Manual heuristic recovery when –tc-heuristic-recover is set to some value other than `OFF`.

Automatic Crash Recovery

Automatic crash recovery occurs during startup when MariaDB needs to recover from a crash and –tc-heuristic-recover is set to `OFF`, which is the default value.

Automatic Crash Recovery with the Binary Log-Based Transaction Coordinator Log

If MariaDB needs to perform automatic crash recovery and if the binary log is enabled, then the error log will contain messages like this:

```
[Note] Recovering after a crash using cmdb-mariadb-0-bin
[Note] InnoDB: Buffer pool(s) load completed at 190313 11:24:29
[Note] Starting crash recovery...
[Note] Crash recovery finished.
```

When the InnoDB-based Binary Log (`--binary-storage-engine=innodb`) is enabled, the binary log is managed transactionally within InnoDB tablespaces. As a result, no separate log exists between InnoDB table data and the binary log. Hence, two-phase commit (2PC) and independent binary log crash recovery are no longer required.

Automatic Crash Recovery with the Memory-Mapped File-Based Transaction Coordinator Log

If MariaDB needs to perform automatic crash recovery and if the binary log is **not** enabled, then the error log will contain messages like this:

```
[Note] Recovering after a crash using tc.log
[Note] InnoDB: Buffer pool(s) load completed at 190313 11:26:32
[Note] Starting crash recovery...
[Note] Crash recovery finished.
```

Manual Heuristic Recovery

Manual heuristic recovery occurs when –tc-heuristic-recover is set to some value other than `OFF` . This might be needed if the server finds prepared transactions during crash recovery that are not in the transaction coordinator log. For example, the error log might contain an error like this:

```
[ERROR] Found 1 prepared transactions! It means that mysqld was not shut down properly last time and
critical recovery information (last binlog or tc.log file) was manually deleted after a crash. You have
to start mysqld with --tc-heuristic-recover switch to commit or rollback pending transactions.
```

When manual heuristic recovery is initiated, MariaDB will ignore information about transactions in the transaction coordinator log during the recovery process. Prepared transactions that are encountered during the recovery process will either be rolled back or committed, depending on the value of –tc-heuristic-recover.

When manual heuristic recovery is initiated, the error log will contain a message like this:

```
[Note] Heuristic crash recovery mode
```

Manual Heuristic Recovery with the Binary Log-Based Transaction Coordinator Log

If –tc-heuristic-recover is set to some value other than `OFF` and if the binary log is enabled, then MariaDB will ignore information about transactions in the binary log during the recovery process. Prepared transactions that are encountered during the recovery process will either be rolled back or committed, depending on the value of –tc-heuristic-recover.

After the recovery process is complete, MariaDB will create a new empty binary log file, so that the old corrupt ones can be ignored.

Manual Heuristic Recovery with the Memory-Mapped File-Based Transaction Coordinator Log

If –tc-heuristic-recover is set to some value other than `OFF` and if the binary log is **not** enabled, then MariaDB will ignore information about transactions in the memory-mapped file defined by the –log-tc option during the recovery process. Prepared transactions that are encountered during the recovery process will either be rolled back or committed, depending on the value of –tc-heuristic-recover.

This page is licensed: CC BY-SA / Gnu FDL

Writing Logs Into Tables

By default, all logs are disabled or written into files. The general query log and the slow query log can also be written to special tables in the `mysql` database. During the startup, entries will always be written into files.

Note that EXPLAIN output will only be recorded if the slow query log is written to a file and not to a table.

To write logs into tables, the log_output server system variable is used. Allowed values are `FILE`, `TABLE` and `NONE`. It is possible to specify multiple values, separated with commas, to write the logs into both tables and files. `NONE` disables logging and has precedence over the other values.

So, to write logs into tables, one of the following settings can be used:

```
SET GLOBAL log_output = 'TABLE';
SET GLOBAL log_output = 'FILE,TABLE';
```

The general log will be written into the general_log table, and the slow query log will be written into the slow_log table. Only a limited set of operations are supported for those special tables. For example, direct DML statements (like `INSERT`) on those tables will fail with an error similar to the following:

```
ERROR 1556 (HY000): You can't use locks with log tables.
```

To flush data to the tables, use FLUSH TABLES instead of FLUSH LOGS.

To empty the contents of the log tables, TRUNCATE TABLE can be used.

The log tables use the CSV storage engine by default. This allows an external program to read the files if needed: normal CSV files are stored in the `mysql` subdirectory, in the data dir. However that engine is slow because it does not support indexes, so you can convert the tables to MyISAM (but not other storage engines). To do so, first temporarily disable logging:

```
SET GLOBAL general_log = 'OFF';
ALTER TABLE mysql.general_log ENGINE = MyISAM;
ALTER TABLE mysql.slow_log ENGINE = MyISAM;
SET GLOBAL general_log = @old_log_state;
```

CHECK TABLE and CHECKSUM TABLE are supported.

CREATE TABLE is supported. ALTER TABLE, RENAME TABLE and DROP TABLE are supported when logging is disabled, but log tables cannot be partitioned.

Contents of log tables are not logged in the binary log, thus cannot be replicated.

Variables and Modes

See Options, System & Status Variables.

A comprehensive, alphabetical reference list of all server command-line options, system variables, and status variables available in MariaDB.

See Server Status Variables.

Documentation for server status variables, which provide information about the server's current state and operation (e.g., `Aborted_connects`, `Uptime`), accessed via `SHOW STATUS`.

See Server System Variables.

Reference for MariaDB Server system variables — how to view and set them, their scope and dynamism, and their effect on connections, caching, logging, and performance.

See NEW_MODE.

Explains the `NEW_MODE` system variable (from MariaDB 11.4), which lets you opt in to new behaviors and optimizations in otherwise stable versions.

See OLD_MODE.

Describes the `OLD_MODE` system variable, used to revert specific behaviors to match older MariaDB or MySQL versions for compatibility purposes during upgrades.

See SQL_MODE.

Complete SQL_MODE reference: set via SET/SET GLOBAL/–sql-mode, view @@SQL_MODE, STRICT_TRANS_TABLES, ANSI_QUOTES, TRADITIONAL, and database emulation.

See SQL_MODE=MSSQL.

SQL_MODE=MSSQL enables Microsoft SQL Server compatibility behaviors in MariaDB.

See SQL_MODE=ORACLE.

SQL_MODE=ORACLE enables Oracle Database compatibility behaviors in MariaDB.

Server Status Variables

> **Note:**
>
> **For a full list of server options, system variables and status variables, see this page.**

Most status variables are described on this page, but some are described elsewhere:

- Aria Status Variables
- Galera Status Variables
- InnoDB Status Variables
- Mroonga Status Variables
- MyRocks Status Variables
- Performance Scheme Status Variables
- Replication and Binary Log Status Variables
- S3 Storage Engine Status Variables
- Server_Audit Status Variables
- Sphinx Status Variables
- Spider Status Variables

Use the SHOW STATUS statement to view status variables. This information also can be obtained using the mariadb-admin extended-status command, or by querying the Information Schema GLOBAL_STATUS and SESSION_STATUS tables.

Issuing a FLUSH STATUS will reset many status variables to zero.

List of Server Status Variables

`Aborted_clients`

- Description: Number of aborted client connections. This can be due to the client not calling mysql_close() before exiting, the client sleeping without issuing a request to the server for more seconds than specified by wait_timeout or interactive_timeout, or by the client program ending in the midst of transferring data. The global value can be flushed by FLUSH STATUS.

- Scope: Global
- Data Type: `numeric`

`Aborted_connects`

- Description: Number of failed server connection attempts. This can be due to a client using an incorrect password, a client not having privileges to connect to a database, a connection packet not containing the correct information, or if it takes more than connect_timeout seconds to get a connect packet. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Aborted_connects_preauth`

- Description: Number of connection attempts that were aborted prior to authentication (regardless of whether or not an error occurred).
- Scope: Global
- Data Type: `numeric`

`Access_denied_errors`

- Description: Number of access denied errors. For details on when this is incremented, see Incrementing of the access_denied_errors status variable.
- Scope: Global
- Data Type: `numeric`

`Acl_column_grants`

- Description: Number of column permissions granted (rows in the mysql.columns_priv table).
- Scope: Global
- Data Type: `numeric`

`Acl_database_grants`

- Description: Number of database permissions granted (rows in the mysql.db table).
- Scope: Global
- Data Type: `numeric`

`Acl_function_grants`

- Description: Number of function permissions granted (rows in the mysql.procs_priv table with a routine type of `FUNCTION`).
- Scope: Global
- Data Type: `numeric`

`Acl_package_body_grants`

- Description:
- Scope: Global
- Data Type: `numeric`

`Acl_package_spec_grants`

- Description:

- Scope: Global
- Data Type: `numeric`

`Acl_procedure_grants`

- Description: Number of procedure permissions granted (rows in the mysql.procs_priv table with a routine type of `PROCEDURE`).
- Scope: Global
- Data Type: `numeric`

`Acl_proxy_users`

- Description: Number of proxy permissions granted (rows in the mysql.proxies_priv table).
- Scope: Global
- Data Type: `numeric`

`Acl_role_grants`

- Description: Number of role permissions granted (rows in the mysql.roles_mapping table).
- Scope: Global
- Data Type: `numeric`

`Acl_roles`

- Description: Number of roles (rows in the mysql.user table where `is_role='Y'`).
- Scope: Global
- Data Type: `numeric`

`Acl_table_grants`

- Description: Number of table permissions granted (rows in the mysql.tables_priv table).
- Scope: Global
- Data Type: `numeric`

`Acl_users`

- Description: Number of users (rows in the mysql.user table where `is_role='N'`).
- Scope: Global
- Data Type: `numeric`

`Busy_time`

- Description: Cumulative time in seconds of activity on connections. Part of User Statistics. Requires the userstat system variable to be set in order to be recorded.
- Scope: Global
- Data Type: `numeric`

`Bytes_received`

- Description: Total bytes received from all clients.
- Scope: Global
- Data Type: `numeric`

`Bytes_sent`

- Description: Total bytes sent to all clients.
- Scope: Global, Session
- Data Type: `numeric`

`Com_admin_commands`

- Description: Number of admin commands executed. These include table dumps, change users, binary log dumps, shutdowns, pings and debugs.
- Scope: Global, Session
- Data Type: `numeric`

`Com_alter_db`

- Description: Number of ALTER DATABASE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_alter_db_upgrade`

- Description: Number of ALTER DATABASE … UPGRADE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_alter_event`

- Description: Number of ALTER EVENT commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_alter_function`

- Description: Number of ALTER FUNCTION commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_alter_procedure`

- Description: Number of ALTER PROCEDURE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_alter_sequence`

- Description: Number of ALTER SEQUENCE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_alter_server`

- Description: Number of ALTER SERVER commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_alter_table`

- Description: Number of ALTER TABLE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_alter_tablespace`

- Description: Number of ALTER TABLESPACE commands executed (unsupported by MariaDB).
- Scope: Global, Session
- Data Type: `numeric`
- Removed: MariaDB 10.7.0

`Com_alter_user`

- Description: Number of ALTER USER commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_analyze`

- Description: Number of ANALYZE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_assign_to_keycache`

- Description: Number of assign to keycache commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_backup`

- Description:
- Scope: Global, Session
- Data Type: `numeric`
- Removed: MariaDB 10.4.1

`Com_backup_lock`

- Description:
- Scope: Global, Session
- Data Type: `numeric`
- Removed: MariaDB 10.4.2

`Com_backup_table`

- Description: Removed in MariaDB 5.5. In older versions, Com_backup_table contains the number of BACKUP TABLE commands executed.
- Scope: Global, Session
- Data Type: `numeric`
- Removed: MariaDB 5.5

`Com_begin`

- Description: Number of BEGIN or START TRANSACTION statements executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_binlog`

- Description: Number of BINLOG commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_call_procedure`

- Description: Number of CALL procedure_name statements executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_change_db`

- Description: Number of USE database_name commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_check`

- Description: Number of CHECK TABLE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_checksum`

- Description: Number of CHECKSUM TABLE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_commit`

- Description: Number of COMMIT commands executed. Differs from Handler_commit, which counts internal commit statements.
- Scope: Global, Session
- Data Type: `numeric`

`Com_compound_sql`

- Description: Number of compound sql statements.
- Scope: Global, Session
- Data Type: `numeric`

`Com_create_db`

- Description: Number of CREATE DATABASE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_create_event`

- Description: Number of CREATE EVENT commands executed. Differs from Executed_events in that it is incremented when the CREATE EVENT is run, and not when the event executes.
- Scope: Global, Session
- Data Type: `numeric`

`Com_create_function`

- Description: Number of CREATE FUNCTION commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_create_index`

- Description: Number of CREATE INDEX commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_create_package`

- Description:
- Scope: Global, Session
- Data Type: `numeric`

`Com_create_package_body`

- Description:
- Scope: Global, Session
- Data Type: `numeric`

`Com_create_procedure`

- Description: Number of CREATE PROCEDURE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_create_role`

- Description: Number of CREATE ROLE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_create_sequence`

- Description: Number of CREATE SEQUENCE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_create_server`

- Description: Number of CREATE SERVER commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_create_table`

- Description: Number of CREATE TABLE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_create_temporary_table`

- Description: Number of CREATE TEMPORARY TABLE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_create_trigger`

- Description: Number of CREATE TRIGGER commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_create_udf`

- Description: Number of CREATE UDF commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_create_user`

- Description: Number of CREATE USER commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_create_view`

- Description: Number of CREATE VIEW commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_dealloc_sql`

- Description: Number of DEALLOCATE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_delete`

- Description: Number of DELETE commands executed. Differs from Handler_delete, which counts the number of times rows have been deleted from tables.
- Scope: Global, Session
- Data Type: `numeric`

`Com_delete_multi`

- Description: Number of multi-table DELETE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_do`

- Description: Number of DO commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_drop_db`

- Description: Number of DROP DATABASE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_drop_event`

- Description: Number of DROP EVENT commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_drop_function`

- Description: Number of DROP FUNCTION commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_drop_index`

- Description: Number of DROP INDEX commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_drop_package`

- Description:
- Scope: Global, Session
- Data Type: `numeric`

`Com_drop_package_body`

- Description:
- Scope: Global, Session
- Data Type: `numeric`

`Com_drop_procedure`

- Description: Number of DROP PROCEDURE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_drop_role`

- Description: Number of DROP ROLE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_drop_sequence`

- Description: Number of DROP SEQUENCE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_drop_server`

- Description: Number of DROP SERVER commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_drop_table`

- Description: Number of DROP TABLE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_drop_temporary_table`

- Description: Number of DROP TEMPORARY TABLE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_drop_trigger`

- Description: Number of DROP TRIGGER commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_drop_user`

- Description: Number of DROP USER commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_drop_view`

- Description: Number of DROP VIEW commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_empty_query`

- Description: Number of queries to the server that do not produce SQL queries. An SQL query simply returning no results does not increment `Com_empty_query` - see Empty_queries instead. An example of an empty query sent to the server is `mariadb --comments -e '-- sql comment'`
- Scope: Global, Session
- Data Type: `numeric`

`Com_execute_immediate`

- Description: Number of EXECUTE IMMEDIATE statements executed.
- Scope: Global, Session

- Data Type: `numeric`

`Com_execute_sql`

- Description: Number of EXECUTE statements executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_flush`

- Description: Number of FLUSH commands executed. This differs from Flush_commands, which also counts internal server flush requests.
- Scope: Global, Session
- Data Type: `numeric`

`Com_get_diagnostics`

- Description: Number of GET DIAGNOSTICS commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_grant`

- Description: Number of GRANT commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_grant_role`

- Description: Number of GRANT role commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_ha_close`

- Description: Number of HANDLER table_name CLOSE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_ha_open`

- Description: Number of HANDLER table_name OPEN commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_ha_read`

- Description: Number of HANDLER table_name READ commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_help`

- Description: Number of HELP commands executed.
- Scope: Global, Session

- Data Type: `numeric`

`Com_insert`

- Description: Number of INSERT commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_insert_select`

- Description: Number of INSERT … SELECT commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_install_plugin`

- Description: Number of INSTALL PLUGIN commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_kill`

- Description: Number of KILL commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_load`

- Description: Number of LOAD commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_load_master_data`

- Description:
- Scope: Global, Session
- Data Type: `numeric`
- Removed: MariaDB 5.5

`Com_load_master_table`

- Description:
- Scope: Global, Session
- Data Type: `numeric`
- Removed: MariaDB 5.5

`Com_multi`

- Description:
- Scope: Global, Session
- Data Type: `numeric`

`Com_lock_tables`

- Description: Number of [lock-tables|LOCK TABLES]] commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_optimize`

- Description: Number of OPTIMIZE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_preload_keys`

- Description:
- Scope: Global, Session
- Data Type: `numeric`

`Com_prepare_sql`

- Description: Number of PREPARE statements executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_purge`

- Description: Number of PURGE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_purge_before_date`

- Description: Number of PURGE BEFORE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_release_savepoint`

- Description: Number of RELEASE SAVEPOINT commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_rename_table`

- Description: Number of RENAME TABLE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_rename_user`

- Description: Number of RENAME USER commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_repair`

- Description: Number of REPAIR TABLE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_replace`

- Description: Number of REPLACE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_replace_select`

- Description: Number of REPLACE … SELECT commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_reset`

- Description: Number of RESET commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_resignal`

- Description: Number of RESIGNAL commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_restore_table`

- Description: Removed in MariaDB 5.5. In older versions, Com_restore_table contains the number of RESTORE TABLE commands executed.
- Scope: Global, Session
- Data Type: `numeric`
- Removed: MariaDB 5.5

`Com_revoke`

- Description: Number of REVOKE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_revoke_all`

- Description: Number of REVOKE ALL commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_revoke_grant`

- Description: Number of REVOKE role commands executed.
- Scope: Global, Session

- Data Type: `numeric`

`Com_rollback`

- Description: Number of ROLLBACK commands executed. Differs from Handler_rollback, which is the number of transaction rollback requests given to a storage engine.
- Scope: Global, Session
- Data Type: `numeric`

`Com_rollback_to_savepoint`

- Description: Number of ROLLBACK … TO SAVEPOINT commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_savepoint`

- Description: Number of SAVEPOINT commands executed. Differs from Handler_savepoint, which is the number of transaction savepoint creation requests.
- Scope: Global, Session
- Data Type: `numeric`

`Com_select`

- Description: Number of SELECT commands executed. Also includes queries that make use of the query cache.
- Scope: Global, Session
- Data Type: `numeric`

`Com_set_option`

- Description: Number of SET OPTION commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_signal`

- Description: Number of SIGNAL statements executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_authors`

- Description: Number of SHOW AUTHORS commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_binlog_events`

- Description: Number of SHOW BINLOG EVENTS statements executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_binlogs`

- Description: Number of SHOW BINARY LOGS commands executed.

- Scope: Global, Session
- Data Type: `numeric`

`Com_show_charsets`

- Description: Number of SHOW CHARACTER SET commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_client_statistics`

- Description: Number of SHOW CLIENT STATISTICS commands executed. Removed in MariaDB 10.1.1 when that statement was replaced by the generic SHOW information_schema_table.
- Scope: Global, Session
- Data Type: `numeric`
- Removed: MariaDB 10.1.1

`Com_show_collations`

- Description: Number of SHOW COLLATION commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_column_types`

- Description:
- Scope: Global, Session
- Data Type: `numeric`
- Removed: MariaDB 5.5

`Com_show_contributors`

- Description: Number of SHOW CONTRIBUTORS commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_create_db`

- Description: Number of SHOW CREATE DATABASE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_create_event`

- Description: Number of SHOW CREATE EVENT commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_create_func`

- Description: Number of SHOW CREATE FUNCTION commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_create_package`

- Description:
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_create_package_body`

- Description:
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_create_proc`

- Description: Number of SHOW CREATE PROCEDURE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_create_table`

- Description: Number of SHOW CREATE TABLE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_create_trigger`

- Description: Number of SHOW CREATE TRIGGER commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_create_user`

- Description: Number of SHOW CREATE USER commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_databases`

- Description: Number of SHOW DATABASES commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_engine_logs`

- Description: Number of SHOW ENGINE LOGS commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_engine_mutex`

- Description: Number of SHOW ENGINE MUTEX commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_engine_status`

- Description: Number of SHOW ENGINE STATUS commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_events`

- Description: Number of SHOW EVENTS commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_errors`

- Description: Number of SHOW ERRORS commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_explain`

- Description: Number of SHOW EXPLAIN commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_fields`

- Description: Number of SHOW COLUMNS or SHOW FIELDS commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_function_status`

- Description: Number of SHOW FUNCTION STATUS commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_generic`

- Description: Number of generic SHOW commands executed, such as SHOW INDEX_STATISTICS and SHOW TABLE_STATISTICS
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_grants`

- Description: Number of SHOW GRANTS commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_keys`

- Description: Number of SHOW INDEX or SHOW KEYS commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_index_statistics`

- Description: Number of SHOW INDEX_STATISTICS commands executed. Removed in MariaDB 10.1.1 when that statement was replaced by the generic SHOW information_schema_table.
- Scope: Global, Session
- Data Type: `numeric`
- Removed: MariaDB 10.1.1

`Com_show_open_tables`

- Description: Number of SHOW OPEN TABLES commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_package_status`

- Description:
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_package_body_status`

- Description:
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_plugins`

- Description: Number of SHOW PLUGINS commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_privileges`

- Description: Number of SHOW PRIVILEGES commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_procedure_status`

- Description: Number of SHOW PROCEDURE STATUS commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_processlist`

- Description: Number of SHOW PROCESSLIST commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_profile`

- Description: Number of SHOW PROFILE commands executed.
- Scope: Global, Session

- Data Type: `numeric`

`Com_show_profiles`

- Description: Number of SHOW PROFILES commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_relaylog_events`

- Description: Number of SHOW RELAYLOG EVENTS commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_status`

- Description: Number of SHOW STATUS commands executed.
- Scope: Global, Session
- Data Type: `numeric` st

`Com_show_storage_engines`

- Description: Number of SHOW STORAGE ENGINES - or `SHOW ENGINES` - commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_table_statistics`

- Description: Number of SHOW TABLE STATISTICS commands executed. Removed in MariaDB 10.1.1 when that statement was replaced by the generic SHOW information_schema_table.
- Scope: Global, Session
- Data Type: `numeric`
- Removed: MariaDB 10.1.1

`Com_show_table_status`

- Description: Number of SHOW TABLE STATUS commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_tables`

- Description: Number of SHOW TABLES commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_triggers`

- Description: Number of SHOW TRIGGERS commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_user_statistics`

- Description: Number of SHOW USER STATISTICS commands executed. Removed in MariaDB 10.1.1 when that statement was replaced by the generic SHOW information_schema_table.
- Scope: Global, Session
- Data Type: `numeric`
- Removed: MariaDB 10.1.1

`Com_show_variable`

- Description: Number of SHOW VARIABLES commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_warnings`

- Description: Number of SHOW WARNINGS commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_shutdown`

- Description: Number of SHUTDOWN commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_stmt_close`

- Description: Number of prepared statements closed (deallocated or dropped).
- Scope: Global, Session
- Data Type: `numeric`

`Com_stmt_execute`

- Description: Number of prepared statements executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_stmt_fetch`

- Description: Number of prepared statements fetched.
- Scope: Global, Session
- Data Type: `numeric`

`Com_stmt_prepare`

- Description: Number of prepared statements prepared.
- Scope: Global, Session
- Data Type: `numeric`

`Com_stmt_reprepare`

- Description: Number of prepared statements reprepared.
- Scope: Global, Session

- Data Type: `numeric`

`Com_stmt_reset`

- Description: Number of prepared statements where the data of a prepared statement which was accumulated in chunks by sending long data has been reset.
- Scope: Global, Session
- Data Type: `numeric`

`Com_stmt_send_long_data`

- Description: Number of prepared statements where the parameter data has been sent in chunks (long data).
- Scope: Global, Session
- Data Type: `numeric`

`Com_truncate`

- Description: Number of TRUNCATE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_uninstall_plugin`

- Description: Number of UNINSTALL PLUGIN commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_unlock_tables`

- Description: Number of UNLOCK TABLES commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_update`

- Description: Number of UPDATE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_update_multi`

- Description: Number of multi-table UPDATE commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_xa_commit`

- Description: Number of XA statements committed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_xa_end`

- Description: Number of XA statements ended.
- Scope: Global, Session

- Data Type: `numeric`

`Com_xa_prepare`

- Description: Number of XA statements prepared.
- Scope: Global, Session
- Data Type: `numeric`

`Com_xa_recover`

- Description: Number of XA RECOVER statements executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_xa_rollback`

- Description: Number of XA statements rolled back.
- Scope: Global, Session
- Data Type: `numeric`

`Com_xa_start`

- Description: Number of XA statements started.
- Scope: Global, Session
- Data Type: `numeric`

`Compression`

- Description: Whether client-server traffic is compressed.
- Scope: Session
- Data Type: `boolean`

`Connection_errors_accept`

- Description: Number of errors that occurred during calls to accept() on the listening port. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Connection_errors_internal`

- Description: Number of refused connections due to internal server errors, for example out of memory errors, or failed thread starts. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Connection_errors_max_connections`

- Description: Number of refused connections due to the max_connections limit being reached. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Connection_errors_peer_address`

- Description: Number of errors while searching for the connecting client IP address. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Connection_errors_select`

- Description: Number of errors during calls to select() or poll() on the listening port. The client would not necessarily have been rejected in these cases. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Connection_errors_tcpwrap`

- Description: Number of connections the libwrap library refused. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Connections`

- Description: Number of connection attempts (both successful and unsuccessful)
- Scope: Global
- Data Type: `numeric`

`Cpu_time`

- Description: Total CPU time used. Part of User Statistics. Requires the userstat system variable to be set in order to be recorded.
- Scope: Global, Session
- Data Type: `numeric`

`Created_tmp_disk_tables`

- Description: Number of on-disk temporary tables created.
- Scope: Global, Session
- Data Type: `numeric`

`Created_tmp_files`

- Description: Number of temporary files created. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Created_tmp_tables`

- Description: Number of in-memory temporary tables created.
- Scope: Global
- Data Type: `numeric`

`Delayed_errors`

- Description: Number of errors which occurred while doing INSERT DELAYED. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Delayed_insert_threads`

- Description: Number of INSERT DELAYED threads.
- Scope: Global
- Data Type: `numeric`

`Delayed_writes`

- Description: Number of INSERT DELAYED rows written. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Delete_scan`

- Description: Number of DELETE s that required a full table scan.
- Scope: Global
- Data Type: `numeric`

`Empty_queries`

- Description: Number of queries returning no results. Note this is not the same as Com_empty_query.
- Scope: Global, Session
- Data Type: `numeric`

`Executed_events`

- Description: Number of times events created with CREATE EVENT have executed. This differs from Com_create_event in that it is only incremented when the event has run, not when it executes.
- Scope: Global, Session
- Data Type: `numeric`

`Executed_triggers`

- Description: Number of times triggers created with CREATE TRIGGER have executed. This differs from Com_create_trigger in that it is only incremented when the trigger has run, not when it executes.
- Scope: Global, Session
- Data Type: `numeric`

`Feature_application_time_periods`

- Description: Number of times a table created with periods has been opened.
- Scope: Global, Session
- Data Type: `numeric`

`Feature_check_constraint`

- Description: Number of times constraints were checked. The global value can be flushed by FLUSH STATUS.
- Scope: Global, Session

- Data Type: `numeric`

`Feature_custom_aggregate_functions`

- Description: Number of queries which make use of custom aggregate functions.
- Scope: Global, Session
- Data Type: `numeric`

`Feature_delay_key_write`

- Description: Number of tables opened that are using delay_key_write. The global value can be flushed by FLUSH STATUS.
- Scope: Global, Session
- Data Type: `numeric`

`Feature_dynamic_columns`

- Description: Number of times the COLUMN_CREATE() function was used.
- Scope: Global, Session
- Data Type: `numeric`

`Feature_fulltext`

- Description: Number of times the MATCH … AGAINST() function was used.
- Scope: Global, Session
- Data Type: `numeric`

`Feature_gis`

- Description: Number of times a table with a any of the geometry columns was opened.
- Scope: Global, Session
- Data Type: `numeric`

`Feature_insert_returning`

- Description:
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.5.0

`Feature_invisible_columns`

- Description: Number of invisible columns in all opened tables.
- Scope: Global, Session
- Data Type: `numeric`

`Feature_json`

- Description: Number of times JSON functionality has been used, such as one of the JSON functions. Does not include the CONNECT engine JSON type, or EXPLAIN/ANALYZE FORMAT=JSON.
- Scope: Global, Session
- Data Type: `numeric`

`Feature_locale`

- Description: Number of times the @@lc_messages variable was assigned into.
- Scope: Global, Session
- Data Type: `numeric`

`Feature_subquery`

- Description: Number of subqueries (excluding subqueries in the FROM clause) used.
- Scope: Global, Session
- Data Type: `numeric`

`Feature_system_versioning`

- Description: Number of times system versioning functionality has been used (opening a table WITH SYSTEM VERSIONING).
- Scope: Global, Session
- Data Type: `numeric`

`Feature_timezone`

- Description: Number of times an explicit timezone (excluding UTC and SYSTEM) was specified.
- Scope: Global, Session
- Data Type: `numeric`

`Feature_trigger`

- Description: Number of triggers loaded.
- Scope: Global, Session
- Data Type: `numeric`

`Feature_window_functions`

- Description: Number of times window functions were used.
- Scope: Global, Session
- Data Type: `numeric`

`Feature_xml`

- Description: Number of times XML functions (EXTRACTVALUE() and UPDATEXML()) were used.
- Scope: Global, Session
- Data Type: `numeric`

`Flush_commands`

- Description: Number of FLUSH statements executed, as well as due to internal server flush requests. This differs from Com_flush, which simply counts FLUSH statements, not internal server flush operations.
- Scope: Global
- Data Type: `numeric`
- Removed: MariaDB 10.5.1

`Handler_commit`

- Description: Number of internal COMMIT requests. Differs from Com_commit, which counts the number of COMMIT statements executed.

- Scope: Global, Session
- Data Type: `numeric`

`Handler_delete`

- Description: Number of times rows have been deleted from tables. Differs from Com_delete, which counts DELETE statements.
- Scope: Global, Session
- Data Type: `numeric`

`Handler_discover`

- Description: Discovery is when the server asks the NDBCLUSTER storage engine if it knows about a table with a given name. Handler_discover indicates the number of times that tables have been discovered in this way.
- Scope: Global, Session
- Data Type: `numeric`

`Handler_external_lock`

- Description: Incremented for each call to the external_lock() function, which generally occurs at the beginning and end of access to a table instance.
- Scope: Global, Session
- Data Type: `numeric`

`Handler_icp_attempts`

- Description: Number of times pushed index condition was checked. The smaller the ratio of Handler_icp_attempts to Handler_icp_match the better the filtering. See Index Condition Pushdown.
- Scope: Global, Session
- Data Type: `numeric`

`Handler_icp_match`

- Description: Number of times pushed index condition was matched. The smaller the ratio of Handler_icp_attempts to Handler_icp_match the better the filtering. See Index Condition Pushdown.
- Scope: Global, Session
- Data Type: `numeric`

`Handler_mrr_init`

- Description: Counts how many MRR (multi-range read) scans were performed. See Multi Range Read optimization.
- Scope: Global, Session
- Data Type: `numeric`

`Handler_mrr_key_refills`

- Description: Number of times key buffer was refilled (not counting the initial fill). A non-zero value indicates there wasn't enough memory to do key sort-and-sweep passes in one go. See Multi Range Read optimization.
- Scope: Global, Session
- Data Type: `numeric`

`Handler_mrr_rowid_refills`

- Description: Number of times rowid buffer was refilled (not counting the initial fill). A non-zero value indicates there wasn't enough memory to do rowid sort-and-sweep passes in one go. See Multi Range Read optimization.
- Scope: Global, Session
- Data Type: `numeric`

`Handler_prepare`

- Description: Number of two-phase commit prepares.
- Scope: Global, Session
- Data Type: `numeric`

`Handler_read_first`

- Description: Number of requests to read the first row from an index. A high value indicates many full index scans, e.g. `SELECT a FROM table_name` where `a` is an indexed column.
- Scope: Global, Session
- Data Type: `numeric`

`Handler_read_key`

- Description: Number of row read requests based on an index value. A high value indicates indexes are regularly being used, which is usually positive.
- Scope: Global, Session
- Data Type: `numeric`

`Handler_read_last`

- Description: Number of requests to read the last row from an index. ORDER BY DESC results in a last-key request followed by several previous-key requests.
- Scope: Global, Session
- Data Type: `numeric`

`Handler_read_next`

- Description: Number of requests to read the next row from an index (in order). Increments when doing an index scan or querying an index column with a range constraint.
- Scope: Global, Session
- Data Type: `numeric`

`Handler_read_prev`

- Description: Number of requests to read the previous row from an index (in order). Mostly used with ORDER BY DESC.
- Scope: Global, Session
- Data Type: `numeric`

`Handler_read_retry`

- Description: Number of read retrys triggered by semi_consistent_read (InnoDB feature).
- Scope: Global
- Data Type: `numeric`

`Handler_read_rnd`

- Description: Number of requests to read a row based on its position. If this value is high, you may not be using joins that don't use indexes properly, or be doing many full table scans.
- Scope: Global, Session
- Data Type: `numeric`

`Handler_read_rnd_deleted`

- Description: Number of requests to delete a row based on its position.
- Scope: Global, Session
- Data Type: `numeric`

`Handler_read_rnd_next`

- Description: Number of requests to read the next row. A large number of these may indicate many table scans and improperly used indexes.
- Scope: Global, Session
- Data Type: `numeric`

`Handler_rollback`

- Description: Number of transaction rollback requests given to a storage engine. Differs from Com_rollback, which is the number of ROLLBACK commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Handler_savepoint`

- Description: Number of transaction savepoint creation requests. Differs from Com_savepoint which is the number of SAVEPOINT commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Handler_savepoint_rollback`

- Description: Number of requests to rollback to a transaction savepoint.
- Scope: Global, Session
- Data Type: `numeric`

`Handler_tmp_delete`

- Description: Number of requests to delete a row in a temporary table.
- Scope: Global, Session
- Data Type: `numeric`

`Handler_tmp_update`

- Description: Number of requests to update a row to a temporary table.
- Scope: Global, Session
- Data Type: `numeric`

`Handler_tmp_write`

- Description: Number of requests to write a row to a temporary table.

- Scope: Global, Session
- Data Type: `numeric`

`Handler_update`

- Description: Number of requests to update a row in a table. Since MariaDB 5.3, this no longer counts temporary tables - see Handler_tmp_update.
- Scope: Global, Session
- Data Type: `numeric`

`Handler_write`

- Description: Number of requests to write a row to a table. Since MariaDB 5.3, this no longer counts temporary tables - see Handler_tmp_write.
- Scope: Global, Session
- Data Type: `numeric`

`Key_blocks_not_flushed`

- Description: Number of key cache blocks which have been modified but not flushed to disk.
- Scope: Global
- Data Type: `numeric`

`Key_blocks_unused`

- Description: Number of unused key cache blocks.
- Scope: Global
- Data Type: `numeric`

`Key_blocks_used`

- Description: Max number of key cache blocks which have been used simultaneously.
- Scope: Global
- Data Type: `numeric`

`Key_blocks_warm`

- Description: Number of key cache blocks in the warm list.
- Scope: Global
- Data Type: `numeric`

`Key_read_requests`

- Description: Number of key cache block read requests. See Optimizing key_buffer_size.
- Scope: Global
- Data Type: `numeric`

`Key_reads`

- Description: Number of physical index block reads. See Optimizing key_buffer_size.
- Scope: Global
- Data Type: `numeric`

`Key_write_requests`

- Description: Number of requests to write a block to the key cache.
- Scope: Global
- Data Type: `numeric`

`Key_writes`

- Description: Number of key cache block write requests
- Scope: Global
- Data Type: `numeric`

`Last_query_cost`

- Description: The most recent query optimizer query cost calculation. Can not be calculated for complex queries, such as subqueries or UNION. It will be set to 0 for complex queries.
- Scope: Session
- Data Type: `numeric`

`Maria_*`

- Description: When the Maria storage engine was renamed Aria, the Maria variables existing at the time were renamed at the same time. See Aria Server Status Variables.

`Max_memory_used`

- Description: The maximum memory allocation used by the current connection.
- Scope: Session
- Data Type: `numeric`
- Introduced: MariaDB 10.6.21

`Max_statement_time_exceeded`

- Description: Number of queries that exceeded the execution time specified by max_statement_time. See Aborting statements that take longer than a certain time to execute.
- Data Type: `numeric`

`Max_tmp_space_used`

- Description: Maximum temporary space used. See Limiting Size of Created Disk Temporary Files and Tables Overview
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 11.5

`Max_used_connections`

- Description: Max number of connections ever open at the same time. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Max_used_connections_time`

- Description: The time at which the last change of max_used_connections occurred. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `datetime`
- Introduced: MariaDB 11.0.2, MariaDB 11.1.1

`Memory_used`

> **Note:**
>
> `Memory_used` now encompasses `Innodb_buffer_pool_bytes_data` rather than reporting them as separate pools.

- Description: Memory used by the server (Global scope) or the current connection (Session scope), in bytes. Since MariaDB 10.6.16, Global scope includes major buffers (InnoDB buffer pool, MyISAM key buffer, and Aria page cache) that were previously excluded.
- Scope: Global, Session
- Data Type: `numeric`

`Memory_used_initial`

- Description: Amount of memory that was used when the server started to service the user connections.
- Scope: Global
- Data Type: `numeric`

`Not_flushed_delayed_rows`

- Description: Number of INSERT DELAYED rows waiting to be written.
- Scope: Global
- Data Type: `numeric`

`Open_files`

- Description: Number of regular files currently opened by the server. Does not include sockets or pipes, or storage engines using internal functions.
- Scope: Global
- Data Type: `numeric`

`Open_streams`

- Description: Number of currently opened streams, usually log files.
- Scope: Global
- Data Type: `numeric`

`Open_table_definitions`

- Description: Number of currently cached .frm files.
- Scope: Global
- Data Type: `numeric`

`Open_tables`

- Description: Number of currently opened tables, excluding temporary tables.

- Scope: Global, Session
- Data Type: `numeric`

`Opened_files`

- Description: Number of files the server has opened.
- Scope: Global
- Data Type: `numeric`

`Opened_plugin_libraries`

- Description: Number of shared libraries that the server has opened to load plugins.
- Scope: Global
- Data Type: `numeric`

`Opened_table_definitions`

- Description: Number of .frm files that have been cached.
- Scope: Global, Session
- Data Type: `numeric`

`Opened_tables`

- Description: Number of tables the server has opened.
- Scope: Global, Session
- Data Type: `numeric`

`Opened_views`

- Description: Number of views the server has opened.
- Scope: Global, Session
- Data Type: `numeric`

`Prepared_stmt_count`

- Description: Current number of prepared statements.
- Scope: Global
- Data Type: `numeric`

`Qcache_free_blocks`

- Description: Number of free query cache memory blocks.
- Scope: Global
- Data Type: `numeric`

`Qcache_free_memory`

- Description: Amount of free query cache memory.
- Scope: Global
- Data Type: `numeric`

`Qcache_hits`

- Description: Number of requests served by the query cache. The global value can be flushed by FLUSH STATUS.

- Scope: Global
- Data Type: `numeric`

`Qcache_inserts`

- Description: Number of queries ever cached in the query cache. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Qcache_lowmem_prunes`

- Description: Number of pruning operations performed to remove old results to make space for new results in the query cache. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Qcache_not_cached`

- Description: Number of queries that are uncacheable by the query cache, or use SQL_NO_CACHE. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Qcache_queries_in_cache`

- Description: Number of queries currently cached by the query cache.
- Scope: Global
- Data Type: `numeric`

`Qcache_total_blocks`

- Description: Number of blocks used by the query cache.
- Scope: Global
- Data Type: `numeric`

`Queries`

- Description: Number of statements executed by the server, excluding COM_PING and COM_STATISTICS. Differs from Questions in that it also counts statements executed within stored programs.
- Scope: Global, Session
- Data Type: `numeric`

`Query_time`

- Description: Cumulative time in seconds, with microsecond precision, of running queries.
- Scope: Global,Session
- Data Type: `numeric`
- Introduced: MariaDB 11.4

`Questions`

- Description: Number of statements executed by the server, excluding COM_PING, COM_STATISTICS, COM_STMT_PREPARE, COM_STMT_CLOSE, and COM_STMT_RESET statements. Differs from Queries in

that it doesn't count statements executed within stored programs.
- Scope: Global, Session
- Data Type: `numeric`

`Resultset_metadata_skipped`

- Description: Number of times sending the metadata has been skipped. Metadata is not resent if metadata does not change between prepare and execute of prepared statement, or between executes.
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.6.0

`Rows_read`

- Description: Number of requests to read a row (excluding temporary tables).
- Scope: Global, Session
- Data Type: `numeric`

`Rows_sent`

- Description:
- Scope: Global, Session
- Data Type: `numeric`

`Rows_tmp_read`

- Description: Number of requests to read a row in a temporary table.
- Scope: Global, Session
- Data Type: `numeric`

`Select_full_join`

- Description: Number of joins which did not use an index. If not zero, you may need to check table indexes.
- Scope: Global, Session
- Data Type: `numeric`

`Select_full_range_join`

- Description: Number of joins which used a range search of the first table.
- Scope: Global, Session
- Data Type: `numeric`

`Select_range`

- Description: Number of joins which used a range on the first table.
- Scope: Global, Session
- Data Type: `numeric`

`Select_range_check`

- Description: Number of joins without keys that check for key usage after each row. If not zero, you may need to check table indexes.
- Scope: Global, Session
- Data Type: `numeric`

`Select_scan`

- Description: Number of joins which used a full scan of the first table.
- Scope: Global, Session
- Data Type: `numeric`

`Slow_launch_threads`

- Description: Number of threads which took longer than slow_launch_time to create. The global value can be flushed by FLUSH STATUS.
- Scope: Global, Session
- Data Type: `numeric`

`Slow_queries`

- Description: Number of queries which took longer than long_query_time to run. The slow query log does not need to be active for this to be recorded.
- Scope: Global, Session
- Data Type: `numeric`

`Sort_merge_passes`

- Description: Number of merge passes performed by the sort algorithm. If too high, you may need to look at improving your query indexes, or increasing the sort_buffer_size.
- Scope: Global, Session
- Data Type: `numeric`

`Sort_priority_queue_sorts`

- Description: The number of times that sorting was done through a priority queue. (The total number of times sorting was done is a sum Sort_range and Sort_scan). See filesort with small LIMIT optimization.
- Scope: Global, Session
- Data Type: `numeric`

`Sort_range`

- Description: Number of sorts which used a range.
- Scope: Global, Session
- Data Type: `numeric`

`Sort_rows`

- Description: Number of rows sorted.
- Scope: Global, Session
- Data Type: `numeric`

`Sort_scan`

- Description: Number of sorts which used a full table scan.
- Scope: Global, Session
- Data Type: `numeric`

`Subquery_cache_hit`

- Description: Counter for all subquery cache hits. The global value can be flushed by FLUSH STATUS.

- Scope: Global, Session
- Data Type: `numeric`

`Subquery_cache_miss`

- Description: Counter for all subquery cache misses. The global value can be flushed by FLUSH STATUS.
- Scope: Global, Session
- Data Type: `numeric`

`Syncs`

- Description: Number of times my_sync() has been called, or the number of times the server has had to force data to disk. Covers the binary log, .frm creation (if these operations are configured to sync) and some storage engines (Archive,CSV, Aria), but not XtraDB/InnoDB).
- Scope: Global, Session
- Data Type: `numeric`

`Table_locks_immediate`

- Description: Number of table locks which were completed immediately. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Table_locks_waited`

- Description: Number of table locks which had to wait. Indicates table lock contention. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Table_open_cache_active_instances`

- Description: Number of active instances for open tables cache lookups.
- Scope:
- Data Type: `numeric`

`Table_open_cache_hits`

- Description: Number of hits for open tables cache lookups.
- Scope:
- Data Type: `numeric`

`Table_open_cache_misses`

- Description: Number of misses for open tables cache lookups.
- Scope:
- Data Type: `numeric`

`Table_open_cache_overflows`

- Description: Number of overflows for open tables cache lookups.
- Scope:
- Data Type: `numeric`

`Tc_log_max_pages_used`

- Description: Max number of pages used by the memory-mapped file-based transaction coordinator log. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Tc_log_page_size`

- Description: Page size of the memory-mapped file-based transaction coordinator log.
- Scope: Global
- Data Type: `numeric`

`Tc_log_page_waits`

- Description: Number of times a two-phase commit was forced to wait for a free memory-mapped file-based transaction coordinator log page. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Threads_cached`

- Description: Number of threads cached in the thread cache. This value will be zero if the thread pool is in use.
- Scope: Global
- Data Type: `numeric`

`Threads_connected`

- Description: Number of clients connected to the server. See Handling Too Many Connections. The `Threads_connected` name is inaccurate when the thread pool is in use, since each client connection does not correspond to a dedicated thread in that case.
- Scope: Global
- Data Type: `numeric`

`Threads_created`

- Description: Number of threads created to respond to client connections. If too large, look at increasing thread_cache_size.
- Scope: Global
- Data Type: `numeric`

`Threads_running`

- Description: Number of client connections that are actively running a command, and not just sleeping while waiting to receive the next command to execute. Some internal system threads also count towards this status variable if they would show up in the output of the SHOW PROCESSLIST statement.
  - In MariaDB 10.3.2 and before, a global counter was updated each time a client connection dispatched a command. In these versions, the global and session status variable are always the same value.
  - In MariaDB 10.3.3 and later, the global counter has been removed as a performance improvement. Instead, when the global status variable is queried, it is calculated dynamically by essentially adding up all the running client connections as they would appear in SHOW PROCESSLIST output. A client connection is only considered to be running if its thread COMMAND value is not equal to `Sleep`. When the session status variable is queried, it always returns `1`.

- Scope: Global
- Data Type: `numeric`

`Tmp_space_used`

- Description: Temporary space used. See Limiting Size of Created Disk Temporary Files and Tables Overview
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 11.5

`Update_scan`

- Description: Number of updates that required a full table scan.
- Scope: Global
- Data Type: `numeric`

`Uptime`

- Description: Number of seconds the server has been running.
- Scope: Global
- Data Type: `numeric`

`Uptime_since_flush_status`

- Description: Number of seconds since the last FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

Server System Variables

Overview

MariaDB has many system variables that can be changed to suit your needs.

> **Note:**
>
> **For a full list of server options, system variables and status variables, see this page.**

Many of the general system variables are described on this page, but others are described elsewhere:

- Aria System Variables
- CONNECT System Variables
- Galera System Variables
- Global Transaction ID System Variables
- HandlerSocket Plugin System Variables
- InnoDB System Variables
- Mroonga System Variables
- MyRocks System Variables
- MyISAM System Variables
- Performance Schema System Variables
- Replication and Binary Log System Variables

- S3 Storage Engine System Variables
- Server_Audit System Variables
- Spider System Variables
- SQL_ERROR_LOG Plugin System Variables
- SSL System Variables
- Threadpool System Variables
- Vector System Variables

See also the Full list of MariaDB options, system and status variables.

Most of these can be set with command line options and many of them can be changed at runtime.
Variables that can be changed at runtime (and therefore are not read-only) are described as “Dynamic” below, and elsewhere in the documentation.

There are a few ways to see the full list of server system variables:

- While in the mariadb client, run:

```
SHOW VARIABLES;
```

- See SHOW VARIABLES for instructions on using this command.
- From your shell, run mariadbd like so:

```
mariadbd --verbose --help
```

- View the Information Schema GLOBAL_VARIABLES, SESSION_VARIABLES, and SYSTEM_VARIABLES tables.

Setting Server System Variables

There are several ways to set server system variables:

- Specify them on the command line:

```
shell> ./mariadbd-safe --aria_group_commit="hard"
```

- Specify them in your my.cnf file (see Configuring MariaDB with my.cnf for more information):

```
aria_group_commit = "hard"
```

- Set them from the mariadb client using the SET command. Only variables that are dynamic can be set at runtime in this way. Note that variables set in this way will not persist after a restart.

```
SET GLOBAL aria_group_commit="hard";
```

By convention, server variables have usually been specified with an underscore in the configuration files, and a dash on the command line. You can however specify underscores as dashes - they are interchangeable.

Variables that take a numeric size can either be specified in full, or with a suffix for easier readability. Valid suffixes are:

Suffix	Description	Value
K	kilobytes	1024
M	megabytes	10242
G	gigabytes	10243

Suffix	Description	Value
T	terabytes	10244 (from MariaDB 10.3.3)
P	petabytes	10245 (from MariaDB 10.3.3)
E	exabytes	10246 (from MariaDB 10.3.3)

The suffix can be upper or lower-case.

List of Server System Variables

`allow_suspicious_udfs`

- Description: Allows use of user-defined functions consisting of only one symbol `x()` without corresponding `x_init()` or `x_deinit()`. That also means that one can load any function from any library, for example `exit()` from `libc.so`. Not recommended unless you require old UDFs with one symbol that cannot be recompiled. Before MariaDB 10.10, available as an option only.
- Command line: `--allow-suspicious-udfs`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`
- Introduced: MariaDB 10.10

`alter_algorithm`

- Description: The implied `ALGORITHM` for ALTER TABLE if no `ALGORITHM` clause is specified. The deprecated variable old_alter_table is an alias for this. The feature was removed in MariaDB 11.5. See ALGORITHM=DEFAULT.
  - `COPY` corresponds to the pre-MySQL 5.1 approach of creating an intermediate table, copying data one row at a time, and renaming and dropping tables.
  - `INPLACE` requests that the operation be refused if it cannot be done natively inside a the storage engine.
  - `DEFAULT` (the default) chooses `INPLACE` if available, and falls back to `COPY`.
  - `NOCOPY` refuses to copy a table.
  - `INSTANT` refuses an operation that would involve any other than metadata changes.
- Command line: `--alter-algorithm=default`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `enumerated`
- Default Value: `DEFAULT`
- Valid Values: `DEFAULT`, `COPY`, `INPLACE`, `NOCOPY`, `INSTANT`
- Introduced: MariaDB 10.3.7
- Deprecated: MariaDB 11.5

`analyze_max_length`

- Description: Prevents collection of column statistics for `CHAR`/`VARCHAR` columns that can be analyzed automatically by `ANALYZE TABLE PERSISTENT`. Columns exceeding this threshold in bytes will be skipped unless included explicitly in `FOR COLUMNS(...)`.
- Command line: `--analyze-max-length=val`
- Scope: Global, Session

- Dynamic: Yes
- Data Type: `INT UNSIGNED`
- Default Value: `4294967295 (4G)`
- Range: `32` to `4294967295`
- Introduced: MariaDB 10.6.23, MariaDB 10.11.14, MariaDB 11.4.8, MariaDB 11.8.3, MariaDB 12.0.2, MariaDB 12.1.1, MariaDB Enterprise Server 10.6, MariaDB Enterprise Server 11.4, MariaDB Enterprise Server 11.8

`analyze_sample_percentage`

- Description: Percentage of rows from the table ANALYZE TABLE will sample to collect table statistics. Set to 0 to let MariaDB decide what percentage of rows to sample.
- Command line: `--analyze-sample-percentage=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `100.000000`
- Range: `0` to `100`
- Introduced: MariaDB 10.4.3

`autocommit`

- Description: If set to 1, the default, all queries are committed immediately. The LOCK IN SHARE MODE and FOR UPDATE clauses therefore have no effect. If set to 0, they are only committed upon a COMMIT statement or rolled back with a ROLLBACK statement. If autocommit is set to 0, and then changed to 1, all open transactions are immediately committed.
- Command line: `--autocommit[=#]`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `1`

`automatic_sp_privileges`

- Description: When set to 1, the default, when a stored routine is created, the creator is automatically granted permission to ALTER (which includes dropping) and to EXECUTE the routine. If set to 0, the creator is not automatically granted these privileges.
- Command line: `--automatic-sp-privileges`, `--skip-automatic-sp-privileges`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `1`

`back_log`

- Description: Connections take a small amount of time to start, and this setting determines the number of outstanding connection requests MariaDB can have, or the size of the listen queue for incoming TCP/IP requests. Requests beyond this will be refused. Increase if you expect short bursts of connections. Cannot be set higher than the operating system limit (see the Unix listen() man page). If not set, set to `0`, or the `--autoset-back-log` option is used, will be autoset to the lower of `900` and (50 + max_connections/5).
- Command line: `--back-log=#`

- Scope: Global
- Dynamic: No
- Type: number
- Default Value:
  - The lower of `900` and (50 + max_connections/5)

`basedir`

- Description: Path to the MariaDB installation directory. Other paths are usually resolved relative to this base directory.
- Command line: `--basedir=path` or `-b path`
- Scope: Global
- Dynamic: No
- Type: directory name

`big_tables`

- Description: If this system variable is set to 1, then temporary tables will be saved to disk instead of memory.
  - This system variable's original intention was to allow result sets that were too big for memory-based temporary tables and to avoid the resulting 'table full' errors.
  - This system variable is no longer needed, because the server can automatically convert large memory-based temporary tables into disk-based temporary tables when they exceed the value of the tmp_memory_table_size system variable.
  - To prevent memory-based temporary tables from being used at all, set the tmp_memory_table_size system variable to `0`.
  - In MariaDB 5.5 and earlier, sql_big_tables is a synonym.
  - From MariaDB 10.5, this system variable is deprecated.
- Command line: `--big-tables`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `0`
- Deprecated: MariaDB 10.5.0
- Removed: MariaDB 12.0

`bind_address`

- Description: By default, the MariaDB server listens for TCP/IP connections on all addresses. You can specify an alternative when the server starts using this option; either a host name, an IPv4 or an IPv6 address, "::" or "" *(all addresses). In some systems, such as Debian and Ubuntu, the bind_address is set to 127.0.0.1, which binds the server to listen on localhost only.* `bind_address` *has always been available as a mariadbd option; from MariaDB 10.3.3 it's also available as a system variable. Before MariaDB 10.6.0 "::" implied listening additionally on IPv4 addresses like ""*. From 10.6.0 onwards it refers to IPv6 stictly. Starting with MariaDB 10.11, a comma-separated list of addresses to bind to can be given. See also Configuring MariaDB for Remote Client Access.
- Command line: `--bind-address=addr`
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value: (Empty string)

- Valid Values: Host name, IPv4, IPv6, ::, *
- Introduced: MariaDB 10.3.3 (as a system variable)

`block_encryption_mode`

- Description: Default block encryption mode for AES_ENCRYPT() and AES_DECRYPT() functions.
- Command line: `--block-encryption-mode=val`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `aes-128-ecb`
- Valid values: `aes-128-ecb`, `aes-192-ecb`, `aes-256-ecb`, `aes-128-cbc`, `aes-192-cbc`, `aes-256-cbc`, `aes-128-ctr`, `aes-192-ctr`, `aes-256-ctr`
- Introduced: MariaDB 11.2.0

`bulk_insert_buffer_size`

- Description: Size in bytes of the per-thread cache tree used to speed up bulk inserts into MyISAM and Aria tables. A value of 0 disables the cache tree.
- Command line: `--bulk-insert-buffer-size=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `8388608`
- Range - 32 bit: `0` to `4294967295`
- Range - 64 bit: `0` to `18446744073709547520`

`character_set_client`

- Description: Determines the character set for queries arriving from the client. It can be set per session by the client, although the server can be configured to ignore client requests with the `--skip-character-set-client-handshake` option. If the client does not request a character set or requests a character set that the server does not support, the global value will be used. utf16, utf16le, utf32 and ucs2 cannot be used as client character sets. From MariaDB 10.6, the `utf8` character set (and related collations) was by default an alias for `utf8mb3` rather than the other way around. From MariaDB 13.1, `utf8` is by default an alias for `utf8mb4`; the previous `utf8mb3` default can be restored with the deprecated `UTF8_IS_UTF8MB3` flag of the old_mode system variable.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `string`
- Default Value:
  - >= MariaDB 11.6: `utf8mb4`
  - <= MariaDB 11.5: `latin1`

`character_set_collations`

- Description: Overrides for character set default collations. Takes a comma-delimited list of character set and collation settings, for example `SET @@character_set_collations = 'utf8mb4=uca1400_ai_ci, latin2=latin2_hungarian_ci';` The new variable will take effect in all cases where a character set is explicitly or implicitly specified without an explicit COLLATE clause, including but not limited to:
  - Column collation

    - Table collation
    - Database collation
    - CHAR(expr USING csname)
    - CONVERT(expr USING csname)
    - CAST(expr AS CHAR CHARACTER SET csname)
    - '' - character string literal
    - _utf8mb3'text' - a character string literal with an introducer
    - _utf8mb3 X'61' - a character string literal with an introducer with hex notation
    - _utf8mb3 0x61 - a character string literal with an introducer with hex hybrid notation
    - @@collation_connection after a SET NAMES without COLLATE
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `string`
- Default Value:
    - `utf8mb3=utf8mb3_uca1400_ai_ci, ucs2=ucs2_uca1400_ai_ci, utf8mb4=utf8mb4_uca1400_ai_ci, utf16=utf16_uca1400_ai_ci, utf32=utf32_uca1400_ai_ci` (>= MariaDB 11.5)
    - Empty (<= MariaDB 11.4)
- Introduced: MariaDB 11.2

`character_set_connection`

- Description: Character set used for number to string conversion, as well as for literals that don't have a character set introducer. From MariaDB 10.6, the `utf8` character set (and related collations) was by default an alias for `utf8mb3` rather than the other way around. From MariaDB 13.1, `utf8` is by default an alias for `utf8mb4`; the previous `utf8mb3` default can be restored with the deprecated `UTF8_IS_UTF8MB3` flag of the old_mode system variable.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `string`
- Default Value:
    - >=MariaDB 11.6: `utf8mb4`
    - >= MariaDB 10.6: `utf8mb3`
    - <= MariaDB 10.5: `utf8`

`character_set_database`

- Description: Character set used by the default database and set by the server whenever the default database is changed. If there's no default database, character_set_database contains the same value as character_set_server. This variable is dynamic, but should not be set manually, only by the server.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `string`
- Default Value: `utf8mb4` (>= MariaDB 11.6.0), `latin1` (<= MariaDB 11.5)

`character_set_filesystem`

- Description: The character set for the filesystem. Used for converting file names specified as a string literal from character_set_client to character_set_filesystem before opening the file. By default, set to `binary`, so no

conversion takes place. This could be useful for statements such as LOAD_FILE() or LOAD DATA INFILE on system where multi-byte file names are use.

- Command line: `--character-set-filesystem=name`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `string`
- Default Value: `binary`

`character_set_results`

- Description: Character set used for results and error messages returned to the client. From MariaDB 10.6, the `utf8` character set (and related collations) was by default an alias for `utf8mb3` rather than the other way around. From MariaDB 13.1, `utf8` is by default an alias for `utf8mb4`; the previous `utf8mb3` default can be restored with the deprecated `UTF8_IS_UTF8MB3` flag of the old_mode system variable.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `string`
- Default Value: `utf8mb3` (>= MariaDB 10.6), `utf8` (<= MariaDB 10.5)

`character_set_server`

- Description: Default character set used by the server. See character_set_database for character sets used by the default database. Defaults may be different on some systems, see for example Differences in MariaDB in Debian.
- Command line: `--character-set-server`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `string`
- Default Value: `utf8mb4` (>= MariaDB 11.6.0), `latin1` (<= MariaDB 11.5)

`character_set_system`

- Description: Character set used by the server to store identifiers, always set to utf8, or its synonym utf8mb3 starting with MariaDB 10.6. From MariaDB 10.6, the `utf8` character set (and related collations) was by default an alias for `utf8mb3` rather than the other way around. From MariaDB 13.1, `utf8` is by default an alias for `utf8mb4`; the previous `utf8mb3` default can be restored with the deprecated `UTF8_IS_UTF8MB3` flag of the old_mode system variable.
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value: `utf8mb3` (>= MariaDB 10.6), `utf8` (<= MariaDB 10.5)

`character_sets_dir`

- Description: Directory where the character sets are installed.
- Command line: `--character-sets-dir=path`
- Scope: Global
- Dynamic: No
- Type: directory name

`check_constraint_checks`

- Description: If set to `0`, will disable constraint checks, for example when loading a table that violates some constraints that you plan to fix later.
- Scope: Global, Session
- Dynamic: Yes
- Type: boolean
- Default: ON

`collation_connection`

- Description: Collation used for the connection character set.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `string`

`collation_database`

- Description: Collation used for the default database. Set by the server if the default database changes, if there is no default database the value from the `collation_server` variable is used. This variable is dynamic, but should not be set manually, only by the server.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `string`

`collation_server`

- Description: Default collation used by the server. This is set to the default collation for a given character set automatically when character_set_server is changed, but it can also be set manually. Defaults may be different on some systems, see for example Differences in MariaDB in Debian.
- Command line: `--collation-server=name`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `string`
- Default Value: `latin1_swedish_ci`

`completion_type`

- Description: The transaction completion type. If set to `NO_CHAIN` or `0` (the default), there is no effect on commits and rollbacks. If set to `CHAIN` or `1`, a COMMIT statement is equivalent to COMMIT AND CHAIN, while a ROLLBACK is equivalent to ROLLBACK AND CHAIN, so a new transaction starts straight away with the same isolation level as transaction that's just finished. If set to `RELEASE` or `2`, a COMMIT statement is equivalent to COMMIT RELEASE, while a ROLLBACK is equivalent to ROLLBACK RELEASE, so the server will disconnect after the transaction completes. Note that the transaction completion type only applies to explicit commits, not implicit commits.
- Command line: `--completion-type=name`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `enumerated`
- Default Value: `NO_CHAIN`
- Valid Values: `0`, `1`, `2`, `NO_CHAIN`, `CHAIN`, `RELEASE`

`concurrent_insert`

- Description: If set to `AUTO` or `1`, the default, MariaDB allows concurrent INSERTs and SELECTs for MyISAM tables with no free blocks in the data (deleted rows in the middle). If set to `NEVER` or `0`, concurrent inserts are disabled. If set to `ALWAYS` or `2`, concurrent inserts are permitted for all MyISAM tables, even those with holes, in which case new rows are added at the end of a table if the table is being used by another thread. If the –skip-new option is used when starting the server, concurrent_insert is set to `NEVER`. Changing the variable only affects new opened tables. Use FLUSH TABLES If you want it to also affect cached tables. See Concurrent Inserts for more.
- Command line: `--concurrent-insert[=value]`
- Scope: Global
- Dynamic: Yes
- Data Type: `enumerated`
- Default Value: `AUTO`
- Valid Values: `0`, `1`, `2`, `AUTO`, `NEVER`, `ALWAYS`

`connect_timeout`

- Description: Time in seconds that the server waits for a connect packet before returning a 'Bad handshake'. Increasing may help if clients regularly encounter 'Lost connection to MySQL server at 'X', system error: error_number' type-errors.
- Command line: `--connect-timeout=#`
- Scope: Global
- Dynamic: Yes
- Type: numeric
- Default Value: `10`
- Range: `2` to `31536000`

`core_file`

- Description: Write a core-file on crashes. The file name and location are system dependent. On Linux it is usually called `core.${PID}`, and it is usually written to the data directory. However, this can be changed.
  - See Enabling Core Dumps for more information.
  - Previously this system variable existed only as an option, but it was also made into a read-only system variable starting with MariaDB 10.3.9, MariaDB 10.2.17 and MariaDB 10.1.35.
  - On Windows >= MariaDB 10.4.3, this option is set by default.
  - Note that the option accepts no arguments; specifying `--core-file` sets the value to `ON`. It cannot be disabled in the case of Windows >= MariaDB 10.4.3.
- Command line: `--core-file`
- Scope: Global
- Dynamic: No
- Type: boolean
- Default Value:
  - Windows >= MariaDB 10.4.3: `ON`
  - All other systems: `OFF`

`datadir`

- Description: Directory where the data is stored.
- Command line: `--datadir=path` or `-h path`

- Scope: Global
- Dynamic: No
- Type: directory name

`date_format`

- Description: Unused.
- Removed: MariaDB 11.3.0

`datetime_format`

- Description: Unused.
- Removed: MariaDB 11.3.0

`debug/debug_dbug`

- Description: Available in debug builds only (built with -DWITH_DEBUG=1). Used in debugging through the DBUG library to write to a trace file. Just using `--debug` will write a trace of what mariadbd is doing to the default trace file.
- Command line: `-#`, `--debug[=debug_options]`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `string`
- Default Value:
  - = MariaDB 10.5: `d:t:i:o,/tmp/mariadbd.trace` (Unix) or `d:t:i:O,\mariadbd.trace` (Windows)
- Debug Options: See the option flags on the mysql_debug page

`debug_no_thread_alarm`

- Description: Disable system thread alarm calls. Disabling it may be useful in debugging or testing, never do it in production.
- Command line: `--debug-no-thead-alarm=#`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`
- Removed: MariaDB 11.4

`debug_sync`

- Description: Used in debugging to show the interface to the Debug Sync facility. MariaDB needs to be configured with -DENABLE_DEBUG_SYNC=1 for this variable to be available.
- Scope: Session
- Dynamic: Yes
- Data Type: `string`
- Default Value: `OFF` or `ON - current signal name`

`default_password_lifetime`

- Description: This defines the global password expiration policy. 0 means automatic password expiration is disabled. If the value is a positive integer N, the passwords must be changed every N day. This behavior can be

overridden using the password expiration options in ALTER USER.

- Command line: `--default-password-lifetime=#`
- Scope: Global
- Dynamic: Yes
- Type: numeric
- Default Value: `0`
- Range: `0` to `4294967295`

`default_regex_flags`

- Description: Introduced to address remaining incompatibilities between PCRE and the old regex library. Accepts a comma-separated list of zero or more of the following values:

Value	Pattern equivalent	Meaning
DOTALL	(?s)	. matches anything including NL
DUPNAMES	(?J)	Allow duplicate names for subpatterns
EXTENDED	(?x)	Ignore white space and comments
EXTRA	(?X)	extra features (e.g. error on unknown escape character)
MULTILINE	(?m)	^ and $ match newlines within data
UNGREEDY	(?U)	Invert greediness of quantifiers

- Command line: `--default-regex-flags=value`
- Scope: Global, Session
- Dynamic: Yes
- Type: enumeration
- Default Value: empty
- Valid Values: `DOTALL`, `DUPNAMES`, `EXTENDED`, `EXTRA`, `MULTILINE`, `UNGREEDY`

`default_storage_engine`

- Description: The default storage engine. The default storage engine must be enabled at server startup, or the server won't start.
- Command line: `--default-storage-engine=name`
- Scope: Global, Session
- Dynamic: Yes
- Type: enumeration
- Default Value: `InnoDB`

`default_table_type`

- Description: A synonym for default_storage_engine. Removed in MariaDB 5.5.
- Command line: `--default-table-type=name`
- Scope: Global, Session
- Dynamic: Yes
- Removed: MariaDB 5.5

`default_tmp_storage_engine`

- Description: Default storage engine that will be used for tables created with CREATE TEMPORARY TABLE where no engine is specified. For internal temporary tables see aria_used_for_temp_tables). The storage engine used must be active or the server will not start. See default_storage_engine for the default for non-temporary tables. Defaults to NULL, in which case the value from default_storage_engine is used. ROCKSDB temporary tables cannot be created. Before MariaDB 10.7, attempting to do so would silently fail, and a MyISAM table would instead be created. From MariaDB 10.7, an error is returned.
- Command line: `--default-tmp-storage-engine=name`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `enumeration`
- Default Value: NULL

`default_week_format`

- Description: Default mode for the WEEK() function. See that page for details on the different modes
- Command line: `--default-week-format=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `7`

`delay_key_write`

- Description: Specifies how MyISAM tables handles CREATE TABLE DELAY_KEY_WRITE. If set to `ON`, the default, any DELAY KEY WRITEs are honored. The key buffer is then flushed only when the table closes, speeding up writes. MyISAM tables should be automatically checked upon startup in this case, and –external locking should not be used, as it can lead to index corruption. If set to `OFF`, DELAY KEY WRITEs are ignored, while if set to `ALL`, all new opened tables are treated as if created with DELAY KEY WRITEs enabled.
- Command line: `--delay-key-write[=name]`
- Scope: Global
- Dynamic: Yes
- Data Type: `enumeration`
- Default Value: `ON`
- Valid Values: `ON`, `OFF`, `ALL`

`delayed_insert_limit`

- Description: After this many rows have been inserted with INSERT DELAYED, the handler will check for and execute any waiting SELECT statements.
- Command line: `--delayed-insert-limit=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `100`
- Range: `1` to `4294967295`

`delayed_insert_timeout`

- Description: Time in seconds that the INSERT DELAYED handler will wait for INSERTs before terminating.
- Command line: `--delayed-insert-timeout=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `300`

`delayed_queue_size`

- Description: Number of rows, per table, that can be queued when performing INSERT DELAYED statements. If the queue becomes full, clients attempting to perform INSERT DELAYED's will wait until the queue has room available again.
- Command line: `--delayed-queue-size=#`
- Scope: Global
- Dynamic: Yes
- Type: numeric
- Default Value: `1000`
- Range: `1 to 4294967295`

`disconnect_on_expired_password`

- Description: When a user password has expired (see User Password Expiry), this variable controls how the server handles clients that are not aware of the sandbox mode. If enabled, the client is not permitted to connect, otherwise the server puts the client in a sandbox mode.
- Command line: `--disconnect-on-expired-password[={0|1}]`
- Scope: Global
- Dynamic: Yes
- Type: boolean
- Default Value: `OFF`

`div_precision_increment`

- Description: The precision of the result of the decimal division will be the larger than the precision of the dividend by that number. By default it's `4`, so `SELECT 2/15` would return 0.1333 and `SELECT 2.0/15` would return 0.13333. After setting div_precision_increment to `6`, for example, the same operation would return 0.133333 and 0.1333333 respectively. `div_precision_increment` is taken into account in intermediate calculations. Instead of truncating decimal values after every division, they are instead truncated for comparison purposes only.
- Command line: `--div-precision-increment=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `4`
- Range: `0` to `30`

`encrypt_tmp_disk_tables`

- Description: Enables automatic encryption of all internal on-disk temporary tables that are created during query execution if aria_used_for_temp_tables=ON is set. See Data at Rest Encryption and Enabling Encryption for

Internal On-disk Temporary Tables.

- Command line: `--encrypt-tmp-disk-tables[={0|1}]`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`encrypt_tmp_files`

- Description: Enables automatic encryption of temporary files, such as those created for filesort operations, binary log file caches, etc. See Data at Rest Encryption.
- Command line: `--encrypt-tmp-files[={0|1}]`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`

`encryption_algorithm`

- Description: Which encryption algorithm to use for table encryption. `aes_cbc` is the recommended one. See Table and Tablespace Encryption.
- Command line: `--encryption-algorithm=value`
- Scope: Global
- Dynamic: No
- Data Type: `enum`
- Default Value: `none`
- Valid Values: `none`, `aes_ecb`, `aes_cbc`, `aes_ctr`
- Introduced: MariaDB 10.1.3
- Removed: MariaDB 10.1.4

`enforce_storage_engine`

- Description: Force the use of a particular storage engine for new tables. Used to avoid unwanted creation of tables using another engine. For example, setting to InnoDB will prevent any MyISAM tables from being created. If another engine is specified in a CREATE TABLE statement, the outcome depends on whether the `NO_ENGINE_SUBSTITUTION` SQL_MODE has been set or not. If set, the query will fail, while if not set, a warning will be returned and the table created according to the engine specified by this variable. The variable has a session scope but is only modifiable by a user with the SUPER privilege.
- Command line: None
- Scope: Session
- Dynamic: Yes
- Data Type: `string`
- Default Value: `none`

`engine_condition_pushdown`

- Description: Deprecated in MariaDB 5.5 and removed and replaced by the optimizer_switch `engine_condition_pushdown={on|off}` flag in MariaDB 10.0. Specifies whether the engine condition pushdown optimization is enabled. Since MariaDB 10.1.1, engine condition pushdown is enabled for all engines that support it.

- Command line: `--engine-condition-pushdown`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`
- Deprecated: MariaDB 5.5
- Removed: MariaDB 10.0

`eq_range_index_dive_limit`

- Description: Limit used for speeding up queries listed by long nested INs. The optimizer will use existing index statistics instead of doing index dives for equality ranges if the number of equality ranges for the index is larger than or equal to this number. If set to `0` (unlimited), index dives are always used.
- Command line: `--eq-range-index-dive-limit=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `200`
- Range: `0` to `4294967295`

`error_count`

- Description: Read-only variable denoting the number of errors from the most recent statement in the current session that generated errors. See SHOW_ERRORS().
- Scope: Session
- Dynamic: Yes
- Data Type: `numeric`

`event_scheduler`

- Description: Status of the Event Scheduler. Can be set to `ON` or `OFF`, while `DISABLED` means it cannot be set at runtime. Setting the variable will cause a load of events if they were not loaded at startup.
- Command line: `--event-scheduler[=value]`
- Scope: Global
- Dynamic: Yes
- Data Type: `enumeration`
- Default Value: `OFF`
- Valid Values: `ON` (or `1`), `OFF` (or `0`), `DISABLED`

`expensive_subquery_limit`

- Description: Number of rows to be examined for a query to be considered expensive, that is, maximum number of rows a subquery may examine in order to be executed during optimization and used for constant optimization.
- Command line: `--expensive-subquery-limit=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `100`
- Range: `0` upwards

`explicit_defaults_for_timestamp`

- Description: This option causes CREATE TABLE to create all TIMESTAMP columns as NULL with the DEFAULT NULL attribute, without this option, TIMESTAMP columns are NOT NULL and have implicit DEFAULT clauses.
- Command line: `--explicit-defaults-for-timestamp=[={0|1}]`
- Scope:
  - Global, Session (>= MariaDB 10.8.4, MariaDB 10.7.5, MariaDB 10.6.9, MariaDB 10.5.17)
  - Global (<= MariaDB 10.8.3, MariaDB 10.7.4, MariaDB 10.6.8, MariaDB 10.5.16)
- Dynamic:
  - Yes (>= MariaDB 10.8.4, MariaDB 10.7.5, MariaDB 10.6.9, MariaDB 10.5.17)
  - No (<= MariaDB 10.8.3, MariaDB 10.7.4, MariaDB 10.6.8, MariaDB 10.5.16)
- Data Type: `boolean`
- Default Value: `ON` (>= MariaDB 10.10), `OFF` (<= MariaDB 10.9)

`external_user`

- Description: External user name set by the plugin used to authenticate the client. `NULL` if native MariaDB authentication is used. For example, from MariaDB 11.6, the Unix socket authentication plugin permits an authentication string, so that the OS and MariaDB user will be different. `external_user` then contains the external OS user. See Authentication Plugin - Unix Socket: Creating Users
- Scope: Session
- Dynamic: No
- Data Type: `string`
- Default Value: `NULL`

`flush`

- Description: Usually, MariaDB writes changes to disk after each SQL statement, and the operating system handles synchronizing (flushing) it to disk. If set to `ON`, the server will synchronize all changes to disk after each statement.
- Command line: `--flush`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`flush_time`

- Description: Interval in seconds that tables are closed to synchronize (flush) data to disk and free up resources. If set to 0, the default, there is no automatic synchronizing tables and closing of tables. This option should not be necessary on systems with sufficient resources.
- Command line: `--flush_time=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`

`foreign_key_checks`

- Description: If set to 1 (the default) foreign key constraints (including ON UPDATE and ON DELETE behavior) InnoDB tables are checked, while if set to 0, they are not checked. `0` is not recommended for normal use, though it can be useful in situations where you know the data is consistent, but want to reload data in a different order from that specified by parent/child relationships. Setting this variable to 1 does not retrospectively check for inconsistencies introduced while set to 0. Setting it to 0 suspends the checks on data only; it does not permit schema changes that would leave a constraint invalid, so a column used in a foreign key still cannot be dropped, renamed, or changed in type, character set, or collation. See Changing the Character Set or Collation of a Foreign Key Column.
- Command line: None
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `1`

`ft_boolean_syntax`

- Description: List of operators supported by an IN BOOLEAN MODE full-text search. If you wish to change, note that each character must be ASCII and non-alphanumeric, the full string must be 14 characters and the first or second character must be a space (marking the behavior by default). Positions 10, 13 and 14 are reserved for future extensions. Also, no duplicates are permitted except for the phrase quoting characters in positions 11 and 12, which may be the same.
- Command line: `--ft-boolean-syntax=name`
- Scope: Global
- Dynamic: Yes
- Data Type: `string`
- Default Value: `+ -><()*:""&|`

`ft_max_word_len`

- Description: Maximum length for a word to be included in the MyISAM full-text index. If this variable is changed, the full-text index must be rebuilt in order for the new value to take effect. The quickest way to do this is by issuing a `REPAIR TABLE table_name QUICK` statement. See innodb_ft_max_token_size for the InnoDB equivalent.
- Command line: `--ft-max-word-len=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `84`
- Minimum Value: `10`

`ft_min_word_len`

- Description: Minimum length for a word to be included in the MyISAM full-text index. If this variable is changed, the full-text index must be rebuilt in order for the new value to take effect. The quickest way to do this is by issuing a `REPAIR TABLE table_name QUICK` statement. See innodb_ft_min_token_size for the InnoDB equivalent.
- Command line: `--ft-min-word-len=#`
- Scope: Global
- Dynamic: No

- Data Type: `numeric`
- Default Value: `4`
- Minimum Value: `1`

`ft_query_expansion_limit`

- Description: For full-text searches, denotes the number of top matches when using `WITH QUERY EXPANSION`.
- Command line: `--ft-query-expansion-limit=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `20`
- Range: `0` to `1000`

`ft_stopword_file`

- Description: File containing a list of stopwords for use in MyISAM full-text searches. Unless an absolute path is specified the file will be looked for in the data directory. The file is not parsed for comments, so all words found become stopwords. By default, a built-in list of words (built from `storage/myisam/ft_static.c file`) is used. Stopwords can be disabled by setting this variable to `''` (an empty string). If this variable is changed, the full-text index must be rebuilt. The quickest way to do this is by issuing a `REPAIR TABLE table_name QUICK` statement. See innodb_ft_server_stopword_table for the InnoDB equivalent.
- Command line: `--ft-stopword-file=file_name`
- Scope: Global
- Dynamic: No
- Data Type: `file name`
- Default Value: `(built-in)`

`general_log`

- Description: If set to 0, the default unless the –general-log option is used, the general query log is disabled, while if set to 1, the general query log is enabled. See log_output for how log files are written. If that variable is set to `NONE`, no logs will be written even if general_query_log is set to `1`.
- Command line: `--general-log`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `0`

`general_log_file`

- Description: Name of the general query log file. If this is not specified, the name is taken from the log-basename setting or from your system hostname with `.log` as a suffix. If –log-basename is also set, `general_log_file` should be placed after in the config files. Later settings override earlier settings, so `log-basename` will override any earlier log file name settings.
- Command line: `--general-log-file=file_name`
- Scope: Global
- Dynamic: Yes
- Data Type: `file name`
- Default Value: `host_name.log`

`group_concat_max_len`

- Description: Maximum length in bytes of the returned result for the functions GROUP_CONCAT(), JSON_OBJECTAGG and JSON_ARRAYAGG.
- Command line: `--group-concat-max-len=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value:
  - `1048576` (1M)
- Range: `4` to `1073741824`

.

`have_compress`

- Description: If the zlib compression library is accessible to the server, this will be set to `YES`, otherwise it will be `NO`. The COMPRESS() and UNCOMPRESS() functions will only be available if set to `YES`.
- Scope: Global
- Dynamic: No

`have_crypt`

- Description: If the crypt() system call is available this variable will be set to `YES`, otherwise it will be set to `NO`. If set to `NO`, the ENCRYPT() function cannot be used.
- Scope: Global
- Dynamic: No

`have_csv`

- Description: If the server supports CSV tables, will be set to `YES`, otherwise will be set to `NO`. Removed in MariaDB 10.0, use the Information Schema PLUGINS table or SHOW ENGINES instead.
- Scope: Global
- Dynamic: No
- Removed: MariaDB 10.0

`have_dynamic_loading`

- Description: If the server supports dynamic loading of plugins, will be set to `YES`, otherwise will be set to `NO`.
- Scope: Global
- Dynamic: No

`have_geometry`

- Description: If the server supports spatial data types, will be set to `YES`, otherwise will be set to `NO`.
- Scope: Global
- Dynamic: No

`have_ndbcluster`

- Description: If the server supports NDBCluster.
- Scope: Global
- Dynamic: No

- Removed: MariaDB 10.0

`have_partitioning`

- Description: If the server supports partitioning, will be set to `YES`, unless the `--skip-partition` option is used, in which case will be set to `DISABLED`. Will be set to `NO` otherwise. Removed in MariaDB 10.0 - SHOW PLUGINS should be used instead.
- Scope: Global
- Dynamic: No
- Removed: MariaDB 10.0

`have_profiling`

- Description: If statement profiling is available, will be set to `YES`, otherwise will be set to `NO`. See SHOW PROFILES() and SHOW PROFILE().
- Scope: Global
- Dynamic: No

`have_query_cache`

- Description: If the server supports the query cache, will be set to `YES`, otherwise will be set to `NO`.
- Scope: Global
- Dynamic: No

`have_rtree_keys`

- Description: If RTREE indexes (used for spatial indexes) are available, will be set to `YES`, otherwise will be set to `NO`.
- Scope: Global
- Dynamic: No

`have_symlink`

- Description: This system variable can be used to determine whether the server supports symbolic links (note that it has no meaning on Windows).
  - If symbolic links are supported, then the value will be `YES`.
  - If symbolic links are not supported, then the value will be `NO`.
  - If symbolic links are disabled with the –symbolic-links option and the `skip` option prefix (i.e. –skip-symbolic-links), then the value will be `DISABLED`.
  - Symbolic link support is required for the INDEX DIRECTORY and DATA DIRECTORY table options.
- Scope: Global
- Dynamic: No

`histogram_size`

- Description: Number of bytes used for a histogram, or, from MariaDB 10.7 when histogram_type is set to `JSON_HB`, number of buckets. If set to 0, no histograms are created by ANALYZE.
- Command line: `--histogram-size=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `254`

- Range: `0` to `255`

`histogram_type`

- Description: Specifies the type of histograms created by ANALYZE..
  - `SINGLE_PREC_HB` - single precision height-balanced.
  - `DOUBLE_PREC_HB` - double precision height-balanced.
  - `JSON_HB` - JSON height-balanced histograms (from MariaDB 10.8)
- Command line: `--histogram-type=value`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `enumeration`
- Default Value:
  - `JSON_HB` (>= MariaDB 11.0)
  - `DOUBLE_PREC_HB` (<= MariaDB 10.11, >= MariaDB 10.4.3)
- Valid Values:
  - `SINGLE_PREC_HB`, `DOUBLE_PREC_HB` (<= MariaDB 10.6)
  - `SINGLE_PREC_HB`, `DOUBLE_PREC_HB`, `JSON_HB` (>= MariaDB 10.8)

`host_cache_size`

- Description: Number of host names that will be cached to avoid resolving. Setting to `0` disables the cache. Changing the value while the server is running causes an implicit FLUSH HOSTS, clearing the host cache and truncating the performance_schema.host_cache table. If you are connecting from a lot of different machines you should consider increasing. Some container configs explicitly set `host_cache_size` to `0`, rather than leave it as the default, `128`.
- Command line: `--host-cache-size=#`.
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `128`
- Range: `0` to `65536`

`hostname`

- Description: When the server starts, this variable is set to the server host name.
- Scope: Global
- Dynamic: No
- Data Type: `string`

`identity`

- Description: A synonym for last_insert_id variable.

`idle_readonly_transaction_timeout`

- Description: Time in seconds that the server waits for idle read-only transactions before killing the connection. If set to `0`, the default, connections are never killed. See also idle_transaction_timeout, idle_write_transaction_timeout and Transaction Timeouts.
- Scope: Global, Session

- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `31536000`

`idle_transaction_timeout`

- Description: Time in seconds that the server waits for idle transactions before killing the connection. If set to `0`, the default, connections are never killed. See also idle_readonly_transaction_timeout, idle_write_transaction_timeout and Transaction Timeouts.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `31536000`

`idle_write_transaction_timeout`

- Description: Time in seconds that the server waits for idle read-write transactions before killing the connection. If set to `0`, the default, connections are never killed. See also idle_transaction_timeout, idle_readonly_transaction_timeout and Transaction Timeouts. Called `idle_readwrite_transaction_timeout` until MariaDB 10.3.2.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `31536000`

`ignore_db_dirs`

- Description: Tells the server that this directory can never be a database. That means two things - firstly it is ignored by the SHOW DATABASES command and INFORMATION_SCHEMA tables. And secondly, USE, CREATE DATABASE and SELECT statements will return an error if the database from the ignored list specified. Use this option for several times if you need to ignore more than one directory. To make the list empty set the void value to the option as –ignore-db-dir=. If the option or configuration is specified multiple times, viewing this value will list the ignore directories separated by commas.
- Command line: `--ignore-db-dirs=dir`.
- Scope: Global
- Dynamic: No
- Data Type: `string`

`in_predicate_conversion_threshold`

- Description: The minimum number of scalar elements in the value list of an IN predicate that triggers its conversion to an IN subquery. Set to 0 to disable the conversion. See Conversion of Big IN Predicates Into Subqueries.
- Command line: `--in-predicate-conversion-threshold=#`
- Scope: Global, Session
- Dynamic: No
- Data Type: `numeric`

- Default Value: `1000`
- Range: `0` to `4294967295`

`in_transaction`

- Description: Session-only and read-only variable that is set to `1` if a transaction is in progress, `0` if not.
- Command line: No
- Scope: Session
- Dynamic: No
- Data Type: `boolean`
- Default Value: `0`

`init_connect`

- Description: String containing one or more SQL statements, separated by semicolons, that will be executed by the server for each client connecting. If there's a syntax error in the one of the statements, the client will fail to connect. For this reason, the statements are not executed for users with the SUPER privilege or, from MariaDB 10.5.2, the CONNECTION ADMIN privilege, who can then still connect and correct the error. See also init_file.
- Command line: `--init-connect=name`
- Scope: Global
- Dynamic: Yes
- Data Type: `string`

`init_file`

- Description: Name of a file containing SQL statements that will be executed by the server on startup. Each statement should be on a new line, and end with a semicolon. See also init_connect.
- Command line: `init-file=file_name`
- Scope: Global
- Dynamic: No
- Data Type: `file name`

`insert_id`

- Description: Value to be used for the next statement inserting a new AUTO_INCREMENT value.
- Scope: Session
- Dynamic: Yes
- Data Type: `numeric`

`interactive_timeout`

- Description: Time in seconds that the server waits for an interactive connection (one that connects with the mysql_real_connect() CLIENT_INTERACTIVE option) to become active before closing it. See also wait_timeout.
- Command line: `--interactive-timeout=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `28800`
- Range: (Windows): `1` to `2147483`
- Range: (Other): `1` to `31536000`

`join_buffer_size`

- Description: Minimum size in bytes of the buffer used for queries that cannot use an index, and instead perform a full table scan. Increase to get faster full joins when adding indexes is not possible, although be aware of memory issues, since joins will always allocate the minimum size. Best left low globally and set high in sessions that require large full joins. In 64-bit platforms, Windows truncates values above 4GB to 4GB with a warning.
- Command line: `--join-buffer-size=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `262144` (256kB)
- Range (non-Windows): `128` to `18446744073709547520`
- Range (Windows): `8228` to `18446744073709547520`

`join_buffer_space_limit`

- Description: Maximum size in bytes of the query buffer, By default 1024_128_10.
- Command line: `--join-buffer-space-limit=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `2097152`
- Range: `2048` to `18446744073709551615`

`join_cache_level`

- Description: Controls which of the eight block-based algorithms can be used for join operations.
  - 1 – flat (Block Nested Loop) BNL
  - 2 – incremental BNL
  - 3 – flat Block Nested Loop Hash (BNLH)
  - 4 – incremental BNLH
  - 5 – flat Batch Key Access (BKA)
  - 6 – incremental BKA
  - 7 – flat Batch Key Access Hash (BKAH)
  - 8 – incremental BKAH
- Command line: `--join-cache-level=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `2`
- Range: `0` to `8`

`keep_files_on_create`

- Description: If a MyISAM table is created with no DATA DIRECTORY option, the .MYD file is stored in the database directory. When set to `0`, the default, if MariaDB finds another .MYD file in the database directory it will overwrite it. Setting this variable to `1` means that MariaDB will return an error instead, just as it usually does in the same situation outside of the database directory. The same applies for .MYI files and no INDEX DIRECTORY

option. This variable was deprecated in MariaDB 10.8.0, but that deprecation was reverted in MariaDB 13.0 and the variable is no longer deprecated.

- Command line: `--keep-files-on-create=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`large_files_support`

- Description: `ON` if the server if was compiled with large file support, else `OFF` .
- Scope: Global
- Dynamic: No

`large_page_size`

- Description: Indicates the size of memory page if large page support (Linux only) is enabled. The page size is determined from the Hugepagesize setting in `/proc/meminfo`. See large_pages. Deprecated and unused (since multiple page size support was added).
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `0` (zero, from MariaDB 10.5.3)
- Deprecated: MariaDB 10.5.3
- Removed: MariaDB 12.0

`large_pages`

- Description: Whether or not large page support is used.
  - This is set with `--large-pages` or disabled with `--skip-large-pages`.
  - Large pages are used for the innodb buffer pool and for online DDL (of size 3* innodb_sort_buffer_size (or 6 when encryption is used)).
  - **Linux**: The `sysctl` variable `kernel.shmmax` must be larger than `llocation`, and the `sysctl` variable `vm.nr_hugepages` must be larger than the usage. The `ulimit` for locked memory must be sufficient to cover the amount used (`ulimit -l` and equivalent in `/etc/security/limits.conf/` or in systemd LimitMEMLOCK). If these operating system controls or insufficient free huge pages are available, the allocation of large pages falls back to conventional memory allocation, and a warning appears in the logs. Only allocations of the default `Hugepagesize` currently occur (see `/proc/meminfo`). The implementation supports multiple page sizes using the Linux built-in huge page feature with the enhancements available in the Linux kernel 3.8 and later.
    - To configure Linux to use huge pages, set the `hugepages` and `hugepagesz` kernel parameters, which can be done via GRUB_CMDLINE_LINUX.
    - To find possible huge page size values, issue this command: `ls -la /sys/devices/system/node/node0/hugepages/`
    - To determine how many huge pages are free, issue this command: `more /sys/devices/system/node/node*/hugepages/hugepages-*kB/free_hugepages`
  - **Windows**: The implementation uses the Windows `GetLargePageMinimum()` syscall to determine the supported page sizes.
    - This works only if the user that runs `mariadbd` has the `SeLockMemoryPrivilege` privilege.

    - **Solaris, FreeBSD, NetBSD**: The implementation uses the `getpagesizes()` syscall to determine the supported page sizes.
        - On Solaris, find possible huge page sizes by calling getpagessizes syscall.
    - **macOS, OpenBSD**: The implementation uses the `getpagesize()` syscall to determine the system's current page size.
- Command line: `--large-pages`, `--skip-large-pages`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`

`last_insert_id`

- Description: Contains the same value as that returned by LAST_INSERT_ID(). Note that setting this variable doesn't update the value returned by the underlying function.
- Scope: Session
- Dynamic: Yes
- Data Type: `numeric`

`lc_messages`

- Description: This system variable can be specified as a locale name. The language of the associated locale will be used for error messages. See Server Locales for a list of supported locales and their associated languages.
    - This system variable is set to `en_US` by default, which means that error messages are in English by default.
    - If this system variable is set to a valid locale name, but the server can't find an error message file for the language associated with the locale, then the default language will be used instead.
    - This system variable is used along with the lc_messages_dir system variable to construct the path to the error messages file.
    - See Setting the Language for Error Messages for more information.
- Command line: `--lc-messages=name`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `string`
- Default Value: `en_us`

`lc_messages_dir`

- Description: This system variable can be specified either as the path to the directory storing the server's error message files or as the path to the directory storing the specific language's error message file. See Server Locales for a list of available locales and their related languages.
    - The server initially tries to interpret the value of this system variable as a path to the directory storing the server's error message files. Therefore, it constructs the path to the language's error message file by concatenating the value of this system variable with the language name of the locale specified by the lc_messages system variable.
    - If the server does not find the error message file for the language, then it tries to interpret the value of this system variable as a direct path to the directory storing the specific language's error message file.
    - See Setting the Language for Error Messages for more information.
- Command line: `--lc-messages-dir=path`

- Scope: Global
- Dynamic: No
- Data Type: `directory name`

`lc_time_names`

- Description: The locale that determines the language used for the date and time functions DAYNAME(), MONTHNAME() and DATE_FORMAT(). Locale names are language and region subtags, for example 'en_ZA' (English - South Africa) or 'es_US: Spanish - United States'. The default is always 'en-US' regardless of the system's locale setting. See server locale for a full list of supported locales.
- Command line: `--lc-time-names=name`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `string`
- Default Value: `en_US`

`license`

- Description: Server license, for example `GPL`.
- Scope: Global
- Dynamic: No
- Data Type: `string`

`local_infile`

- Description: If set to `1`, LOCAL is supported for LOAD DATA INFILE statements. If set to `0`, usually for security reasons, attempts to perform a LOAD DATA LOCAL will fail with an error message.
- Command line: `--local-infile=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `ON`

`lock_wait_timeout`

- Description: Timeout in seconds for attempts to acquire metadata locks. Statements using metadata locks include FLUSH TABLES WITH READ LOCK, LOCK TABLES, HANDLER and DML and DDL operations on tables, stored procedures and functions, and views. The timeout is separate for each attempt, of which there may be multiple in a single statement. `0` means no wait. See WAIT and NOWAIT.
- Command line: `--lock-wait-timeout=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value:
  - `86400` (1 day)
- Range:
  - `0` to `31536000`

`locked_in_memory`

- Description: Indicates whether –memlock was used to lock mariadbd in memory.

- Command line: `--memlock`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`

`log`

- Description: Deprecated and removed in MariaDB 10.0, use general_log instead.
- Command line: `-l [filename]` or `--log[=filename]`
- Scope: Global
- Dynamic: Yes
- Data Type: `string`
- Default Value: `OFF`
- Removed: MariaDB 10.0

`log_disabled_statements`

- Description: If set, the specified type of statements (slave and/or stored procedure statements) will not be logged to the general log. Multiple values are comma-separated, without spaces.
- Command line: `--log-disabled_statements=value`
- Scope: Global, Session
- Dynamic: No
- Data Type: `set`
- Default Value: `sp`
- Valid Values: `slave` and/or `sp`, or empty string for none

`log_error`

- Description: Specifies the name of the error log. If –console is specified later in the configuration (Windows only) or this option isn't specified, errors will be logged to stderr. If no name is provided, errors will still be logged to `hostname.err` in the `datadir` directory by default. If a configuration file sets `--log-error`, one can reset it with `--skip-log-error` (useful to override a system wide configuration file). MariaDB always writes its error log, but the destination is configurable. See error log for details. Note that if –log-basename is also set, `log_error` should be placed after in the config files. Later settings override earlier settings, so `log-basename` will override any earlier log file name settings.
- Command line: `--log-error[=name]`, `--skip-log-error`
- Scope: Global
- Dynamic: No
- Data Type: `file name`
- Default Value: (empty string)

`log_output`

- Description: How the output for the general query log and the slow query log is stored. By default, written to file (`FILE`), it can also be stored in the general_log and slow_log tables in the mysql database (`TABLE`) or not stored at all (`NONE`). More than one option can be chosen at the same time, with `NONE` taking precedence if present. Logs will not be written if logging is not enabled. See Writing logs into tables, and the slow_query_log and general_log server system variables.
- Command line: `--log-output=name`

- Scope: Global
- Dynamic: Yes
- Data Type: `set`
- Default Value: `FILE`
- Valid Values: `TABLE`, `FILE` or `NONE`

`log_queries_not_using_indexes`

- Description: Queries that don't use an index, or that perform a full index scan where the index doesn't limit the number of rows, will be logged to the slow query log (regardless of time taken). The slow query log needs to be enabled for this to have an effect. Mapped to `log_slow_filter='not_using_index'` from MariaDB 10.3.1.
- Command line: `--log-queries-not-using-indexes`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`log_slow_admin_statements`

- Description: Log slow OPTIMIZE, ANALYZE, ALTER and other administrative statements to the slow log if it is open. See also log_slow_disabled_statements and log_slow_filter. Deprecated, use log_slow_filter without `admin`.
- Command line: `--log-slow-admin-statements`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value:
  - `ON`
- Deprecated: MariaDB 11.0.1

`log_slow_disabled_statements`

- Description: If set, the specified type of statements will not be logged to the slow query log. See also log_slow_admin_statements and log_slow_filter.
- Command line: `--log-slow-disabled_statements=value`
- Scope: Global, Session
- Dynamic: No
- Data Type: `set`
- Default Value: `sp`
- Valid Vales: `admin`, `call`, `slave` and/or `sp`

`log_slow_filter`

- Description: Comma-delimited string (without spaces) containing one or more settings for filtering what is logged to the slow query log. If a query matches one of the types listed in the filter, and takes longer than long_query_time, it will be logged (except for 'not_using_index' which is always logged if enabled, regardless of the time). Sets log-slow-admin-statements to ON. See also log_slow_disabled_statements.
  - `admin` log administrative queries (create, optimize, drop etc…)
  - `filesort` logs queries that use a filesort.
  - `filesort_on_disk` logs queries that perform a filesort on disk.

    - `filesort_priority_queue`
    - `full_join` logs queries that perform a join without indexes.
    - `full_scan` logs queries that perform full table scans.
    - `not_using_index` logs queries that don't use an index, or that perform a full index scan where the index doesn't limit the number of rows. Disregards long_query_time, unlike other options. log_queries_not_using_indexes maps to this option. From MariaDB 10.3.1.
    - `query_cache` log queries that are resolved by the query cache.
    - `query_cache_miss` logs queries that are not found in the query cache.
    - `tmp_table` logs queries that create an implicit temporary table.
    - `tmp_table_on_disk` logs queries that create a temporary table on disk.
- Command line: `log-slow-filter=value1[,value2...]`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `enumeration`
- Default Value:
    - `admin`, `filesort`, `filesort_on_disk`, `filesort_priority_queue`, `full_join`, `full_scan`, `query_cache`, `query_cache_miss`, `tmp_table`, `tmp_table_on_disk`
- Valid Values:
    - `admin`, `filesort`, `filesort_on_disk`, `filesort_priority_queue`, `full_join`, `full_scan`, `not_using_index`, `query_cache`, `query_cache_miss`, `tmp_table`, `tmp_table_on_disk`

`log_slow_max_warnings`

- Description: Max numbers of warnings printed to slow query log per statement
- Command line: `log-slow-max-warnings=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `10`
- Range: `0` to `1000`
- Introduced: MariaDB 10.6.16, MariaDB 10.10.7, MariaDB 10.11.6, MariaDB 11.0.4, MariaDB 11.1.3

`log_slow_min_examined_row_limit`

- Description: Don't write queries to slow query log that examine fewer rows than the set value. If set to `0`, the default, no row limit is used. `min_examined_row_limit` is an alias. From MariaDB 11.7, queries slower than log_slow_always_query_time will always be logged.
- Command line: `--log-slow-min-examined-row-limit=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0-4294967295`
- Introduced: MariaDB 10.11

`log_slow_queries`

- Description: Deprecated and removed in MariaDB 10.0, use slow_query_log instead.

- Command line: `--log-slow-queries[=name]`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`
- Removed: MariaDB 10.0

`log_slow_query`

- Description: If set to 0, the default unless the –slow-query-log option is used, the slow query log is disabled, while if set to 1 (both global and session variables), the slow query log is enabled. Named slow_query_log before MariaDB 10.11.0, which is now an alias.
- Command line: `--slow-query-log`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `0`
- Introduced: MariaDB 10.11.0
- See also: See log_output to see how log files are written. If that variable is set to `NONE`, no logs will be written even if log_slow_query is set to `1`.

`log_slow_query_file`

- Description: Name of the slow query log file. Before MariaDB 10.11, was named slow_query_log_file. This was named `log_slow_query_file_name` in the MariaDB 10.11.0 preview release. If –log-basename is also set, `log_slow_query_file` should be placed after in the config files. Later settings override earlier settings, so `log-basename` will override any earlier log file name settings.
- Command line: `--log-slow-query-file=file_name`
- Scope: Global
- Dynamic: Yes
- Data Type: `file name`
- Default Value: `host_name-slow.log`
- Introduced: MariaDB 10.11.0

`log_slow_query_time`

- Description: If a query takes longer than this many seconds to execute (microseconds can be specified too), the Slow_queries status variable is incremented and, if enabled, the query is logged to the slow query log. Before MariaDB 10.11, was named long_query_time. Affected by log_slow_rate_limit and log_slow_min_examined_row_limit.
- Command line: `--log-slow-query-time=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `10.000000`
- Range: `0` to `31536000`
- Introduced: MariaDB 10.11.0

`log_slow_rate_limit`

- Description: The slow query log will log every this many queries. The default is `1`, or every query, while setting it to `20` would log every 20 queries, or five percent. Aims to reduce I/O usage and excessively large slow query logs. See also Slow Query Log Extended Statistics. From MariaDB 11.7, queries slower than log_slow_always_query_time will always be logged.
- Command line: `log-slow-rate-limit=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `1`
- Range: `1` upwards

`log_slow_verbosity`

- Description: Controls information to be added to the slow query log. Options are added in a comma-delimited string. See also Slow Query Log Extended Statistics. log_slow_verbosity is not supported when log_output='TABLE'.
  - `query_plan` logs query execution plan information
  - `innodb` Alias to `engine` (from MariaDB 10.6.15 and MariaDB 10.11.5), previously ignored.
  - `explain` prints EXPLAIN output in the slow query log. See EXPLAIN in the Slow Query Log.
  - `engine` Logs engine statistics (from MariaDB 10.6.15 and MariaDB 10.11.5).
  - `warnings` Print all errors, warnings and notes for the statement to the slow query log. (from MariaDB 10.6.16).
  - `all` Enables all above options (From MariaDB 10.6.16)
  - `full` Enables all above options.
- Command line: `log-slow-verbosity=value1[,value2...]`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `enumeration`
- Default Value: (Empty)
- Valid Values:
  - > = MariaDB 10.6.16, MariaDB 10.11.6: (Empty), `query_plan`, `innodb`, `explain`, `engine`, `warnings`, `all`, `full`
  - > = MariaDB 10.6.15, MariaDB 10.11.5: (Empty), `query_plan`, `innodb`, `explain`, `engine`, `full`
  - <= MariaDB 10.6.14, MariaDB 10.11.4: (Empty), `query_plan`, `innodb`, `explain`

`log_tc_size`

- Description: Defines the size in bytes of the memory-mapped file-based transaction coordinator log, which is only used if the binary log is disabled. If you have two or more XA-capable storage engines enabled, then a transaction coordinator log must be available. This size is defined in multiples of 4096. See Transaction Coordinator Log for more information. Also see the –log-tc server option and the –tc-heuristic-recover option.
- Command line: `log-tc-size=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`

- Default Value: `24576`
- Range: `12288` to `18446744073709551615`

`log_warnings`

- Description: Determines which additional warnings are logged. Setting to `0` disables additional warning logging. Note that this does not prevent all warnings, there is a core set of warnings that will always be written to the error log. The additional warnings are as follows:
  - log_warnings = 0
    - No notes from the event scheduler, only warnings and errors (from MariaDB 10.11.16, 11.4.10, 11.8.6, 12.2.2)
  - log_warnings >= 1
    - Only startup and shutdown event scheduler notes (from MariaDB 10.11.16, 11.4.10, 11.8.6, 12.2.2)
    - Event scheduler information.
    - System signals.
    - Wrong usage of `--user`.
    - Failed `setrlimit()` and `mlockall()`.
    - Changed limits.
    - Wrong values of `lower_case_table_names` and `stack_size`.
    - Wrong values for command line options.
    - Start log position and some master information when starting slaves.
    - Slave reconnects.
    - Killed slaves.
    - Error reading relay logs.
    - Unsafe statements for statement-based replication. If this warning occurs frequently, it is throttled to prevent flooding the log.
    - Disabled plugins that one tried to enable or use.
    - UDF files that didn't include the required init functions.
    - DNS lookup failures.
  - log_warnings >= 2
    - Access denied errors.
    - Connections aborted or closed due to errors or timeouts.
    - Table handler errors.
    - Messages related to the files used to persist replication state:
      - Either the default `master.info` file or the file that is configured by the master_info_file option.
      - Either the default `relay-log.info` file or the file that is configured by the relay_log_info_file system variable.
    - Information about a master's binary log dump thread.
  - log_warnings >= 3
    - All errors and warnings during MyISAM repair and auto recover.
    - Information about old-style language options.
    - Information about progress of InnoDB online DDL.
  - log_warnings >=4
    - Connections aborted due to "Too many connections" errors.
    - Connections closed normally without authentication.
    - Connections aborted due to KILL.

        - Connections closed due to released connections, such as when completion_type is set to `RELEASE`.
        - Could not read packet: (a lot more information)
        - All read/write errors for a connection are logged to the error log.
    - log_warnings >=9
        - Information about initializing plugins.

- Command line: `-W [level]` or `--log-warnings[=level]`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `2`
- Range: `0` to `4294967295`

`long_query_time`

- Description: If a query takes longer than this many seconds to execute (microseconds can be specified too), the Slow_queries status variable is incremented and, if enabled, the query is logged to the slow query log. From MariaDB 10.11.0, this is an alias for log_slow_query_time.
- Command line: `--long-query-time=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `10.000000`
- Range: `0` upwards

`low_priority_updates`

- Description: If set to 1 (0 is the default), for storage engines that use only table-level locking (Aria, MyISAM, MEMORY and MERGE), all INSERTs, UPDATEs, DELETEs and LOCK TABLE WRITEs will wait until there are no more SELECTs or LOCK TABLE READs pending on the relevant tables. Set this to 1 if reads are prioritized over writes.
    - In MariaDB 5.5 and earlier, sql_low_priority_updates is a synonym.
- Command line: `--low-priority-updates`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `0`

`lower_case_file_system`

- Description: Read-only variable describing whether the file system is case-sensitive. If set to `OFF`, file names are case-sensitive. If set to `ON`, they are not case-sensitive.
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `##`

`lower_case_table_names`

- Description: If set to `0` (the default on Unix-based systems), table names and aliases and database names are compared in a case-sensitive manner. If set to `1` (the default on Windows), names are stored in lowercase and not compared in a case-sensitive manner. If set to `2` (the default on Mac OS X), names are stored as declared but compared in lowercase.
  This system variable's value cannot be changed after the datadir has been initialized. lower_case_table_names is set when a MariaDB instance starts, and it remains constant afterwards.
- Command line: `--lower-case-table-names[=#]`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `0` (Unix), `1` (Windows), `2` (Mac OS X)
- Range: `0` to `2`

`max_allowed_packet`

- Description: Maximum size in bytes of a packet or a generated/intermediate string. The packet message buffer is initialized with the value from net_buffer_length, but can grow up to max_allowed_packet bytes. Set as large as the largest BLOB, in multiples of 1024. If this value is changed, it should be changed on the client side as well. See slave_max_allowed_packet for a specific limit for replication purposes.
- Command line: `--max-allowed-packet=#`
- Scope: Global, Session
- Dynamic: Yes (Global), No (Session)
- Data Type: `numeric`
- Default Value:
  - `16777216` (16M)
  - `1073741824` (1GB) (client-side)
- Range: `1024` to `1073741824`

`max_connect_errors`

- Description: Limit to the number of successive failed connects from a host before the host is blocked from making further connections. The count for a host is reset to zero if they successfully connect. To unblock, flush the host cache with a FLUSH HOSTS statement or mariadb-admin flush-hosts. The performance_schema.host_cache table contains the status of the current hosts.
- Command line: `--max-connect-errors=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `100`
- Range: `1` to `4294967295`

`max_connections`

- Description: The maximum number of simultaneous client connections. See also Handling Too Many Connections. Note that this value affects the number of file descriptors required on the operating system. Minimum was changed from `1` to `10` to avoid possible unexpected results for the user (MDEV-18252). Note that MariaDB always has one reserved connection for a `SUPER` (or `CONNECTION ADMIN` user). Additionally, it can listen on a separate port, so will be available even when the max_connections limit is reached.

- Command line: `--max-connections=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `151`
- Range: `10` to `100000`

> **Note:**
>
> **Systemd thread limit (MDEV-30236)**
> When running MariaDB under systemd, be aware that systemd's default `TasksMax` (≈ 4,915 tasks per service) may prevent reaching high `max_connections` values—even if configured higher. Starting with MariaDB 10.4.33, the systemd unit includes:
>
> ```
> [Service]
> TasksMax=infinity
> ```
>
> This setting removes the artificial cap, allowing `max_connections` to scale per your configuration (subject to OS memory and thread limits).

`max_delayed_threads`

- Description: Limits to the number of INSERT DELAYED threads. Once this limit is reached, the insert is handled as if there was no DELAYED attribute. If set to `0`, DELAYED is ignored entirely. The session value can only be set to `0` or to the same as the global value.
- Command line: `--max-delayed-threads=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `20`
- Range: `0` to `16384`

`max_digest_length`

- Description: Maximum length considered for computing a statement digest, such as used by the Performance Schema and query rewrite plugins. Statements that differ after this many bytes produce the same digest, and are aggregated for statistics purposes. The variable is allocated per session. Increasing will allow longer statements to be distinguished from each other, but increase memory use, while decreasing will reduce memory use, but more statements may become indistinguishable.
- Command line: `--max-digest-length=#`
- Scope: Global,
- Dynamic: No
- Data Type: `numeric`
- Default Value: `1024`
- Range: `0` to `1048576`

`max_error_count`

- Description: Specifies the maximum number of messages stored for display by SHOW ERRORS and SHOW WARNINGS statements.
- Command line: `--max-error-count=#`

- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `64`
- Range: `0` to `65535`

`max_heap_table_size`

- Description: Maximum size in bytes for user-created MEMORY tables. Setting the variable while the server is active has no effect on existing tables unless they are recreated or altered. The smaller of max_heap_table_size and tmp_table_size also limits internal in-memory tables. When the maximum size is reached, any further attempts to insert data will receive a “table … is full” error. Temporary tables created with CREATE TEMPORARY will not be converted to Aria, as occurs with internal temporary tables, but will also receive a table full error.
- Command line: `--max-heap-table-size=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `16777216`
- Range : `16384` to `4294966272`

`max_insert_delayed_threads`

- Description: Synonym for max_delayed_threads.

`max_join_size`

- Description: Statements will not be performed if they are likely to need to examine more than this number of rows, row combinations or do more disk seeks. Can prevent poorly-formatted queries from taking server resources. Changing this value to anything other the default will reset sql_big_selects to 0. If sql_big_selects is set again, max_join_size will be ignored. This limit is also ignored if the query result is sitting in the query cache. Previously named sql_max_join_size, which is still a synonym.
- Command line: `--max-join-size=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `18446744073709551615`
- Range: `1` to `18446744073709551615`

`max_length_for_sort_data`

- Description: Used to decide which algorithm to choose when sorting rows. If the total size of the column data, not including columns that are part of the sort, is less than `max_length_for_sort_data`, then we add these to the sort key. This can speed up the sort as we don’t have to re-read the same row again later. Setting the value too high can slow things down as there will be a higher disk activity for doing the sort.
- Command line: `--max-length-for-sort-data=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `1024`
- Range: `4` to `8388608`

`max_long_data_size`

- Description: Maximum size for parameter values sent with mysql_stmt_send_long_data(). If not set, will default to the value of max_allowed_packet. Deprecated in MariaDB 5.5 and removed in MariaDB 10.5.0; use max_allowed_packet instead.
- Command line: `--max-long-data-size=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `16777216` (16M)
- Range: `1024` to `4294967295`
- Deprecated: MariaDB 5.5
- Removed: MariaDB 10.5.0

`max_open_cursors`

- Description: The maximum number of open cursors allowed per session.
- Command line: `--max-open-cursors=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `50`
- Range: `0` to 65536
- Introduced: MariaDB 12.0

`max_password_errors`

- Description: The maximum permitted number of failed connection attempts due to an invalid password before a user is blocked from further connections. FLUSH_PRIVILEGES will permit the user to connect again. This limit is not applicable for users with the SUPER privilege or, from MariaDB 10.5.2, the CONNECTION ADMIN privilege, with a hostname of localhost, 127.0.0.1 or ::1. See also the Information Schema USERS table.
- Command line: `--max-password-errors=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `4294967295`
- Range: `1` to `4294967295`

`max_prepared_stmt_count`

- Description: Maximum number of prepared statements on the server. Can help prevent certain forms of denial-of-service attacks. If set to `0`, no prepared statements are permitted on the server.
- Command line: `--max-prepared-stmt-count=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `16382`
- Range: `0` to `4294967295`

`max_recursive_iterations`

- Description: Maximum number of iterations when executing recursive queries, used to prevent infinite loops in recursive CTEs.
- Command line: `--max-recursive-iterations=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `1000` (>= MariaDB 10.6.0), `4294967295` (<= MariaDB 10.5)
- Range: `0` to `4294967295`

`max_rowid_filter_size`

- Description: The maximum size of the container of a rowid filter.
- Command line: `--max-rowid-filter-size=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `131072`
- Range: `1024` to `18446744073709551615`

`max_seeks_for_key`

- Description: The optimizer assumes that the number specified here is the most key seeks required when searching with an index, regardless of the actual index cardinality. If this value is set lower than its default and maximum, indexes will tend to be preferred over table scans.
- Command line: `--max-seeks-for-key=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `4294967295`
- Range: `1` to `4294967295`

`max_session_mem_used`

- Description: Amount of memory a single user session is allowed to allocate. This limits the value of the session variable Memory_used.
- Command line: `--max-session-mem-used=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `9223372036854775807` (8192 PB)
- Range: `8192` to `18446744073709551615`

`max_sort_length`

- Description: Maximum size in bytes used for sorting data values - anything exceeding this is ignored. The server uses only the first `max_sort_length` bytes of each value and ignores the rest. Increasing this may require sort_buffer_size to be increased (especially if ER_OUT_OF_SORTMEMORY errors start appearing). From MariaDB 11.7, a warning is generated when max_sort_length is exceeded.

- Command line: `--max-sort-length=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `1024`
- Range:
  - `4` to `8388608` (<= MariaDB 10.4.13, MariaDB 10.5.3)
  - `8` to `8388608` (>= MariaDB 10.4.14, MariaDB 10.5.4)
  - `64` to `8388608` (>= MariaDB 10.4.16, MariaDB 10.5.7)

`max_sp_recursion_depth`

- Description: Permitted number of recursive calls for a stored procedure. `0`, the default, no recursion is permitted. Increasing this value increases the thread stack requirements, so you may need to increase thread_stack as well. This limit doesn't apply to stored functions.
- Command line: `--max-sp-recursion-depth[=#]`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `255`

`max_statement_time`

- Description: Maximum time in seconds that a query can execute before being aborted. This includes all queries, not just SELECT statements, but excludes statements in stored procedures. If set to 0, no limit is applied. See Aborting statements that take longer than a certain time to execute for details and limitations. Useful when combined with SET STATEMENT for limiting the execution times of individual queries. Replicas are not affected by this variable, however, from MariaDB 10.10, there's slave_max_statement_time that sets the limit to abort queries on a replica.
- Command line: `--max-statement-time[=#]`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0.000000`
- Range: `0` to `31536000`

`max_tmp_tables`

- Description: Unused.
- Removed: MariaDB 11.3.0

`max_user_connections`

- Description:
  Maximum simultaneous connections permitted for each user account. When set to `0`, there is no per user limit. Setting it to `-1` stops users without the SUPER privilege or, from MariaDB 10.5.2, the CONNECTION ADMIN privilege, from connecting to the server. The session variable is always read-only, and only privileged users can modify user limits. The session variable defaults to the global `max_user_connections` variable, unless the user's specific MAX_USER_CONNECTIONS resource option is non-zero. When both global variable and the

user resource option are set, the user's MAX_USER_CONNECTIONS is used. Note: This variable does not affect users with the SUPER privilege or, from MariaDB 10.5.2, the CONNECTION ADMIN privilege.

- Command line: `--max-user-connections=#`
- Scope: Global, Session
- Dynamic: Yes, (except when globally set to `0` or `-1`)
- Data Type: `numeric`
- Default Value: `0`
- Range: `-1` to `4294967295`

`max_write_lock_count`

- Description: Read lock requests will be permitted for processing after this many write locks. Applies only to storage engines that use table level locks (thr_lock), so no effect with InnoDB or Archive.
- Command line: `--max-write-lock-count=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `4294967295`
- Range: `1` to `4294967295`

`metadata_locks_cache_size`

- Description: Unused since 10.1.4
- Command line: `--metadata-locks-cache-size=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `1024`
- Range: `1` to `1048576`

`metadata_locks_hash_instances`

- Description: Unused since 10.1.4
- Command line: `--metadata-locks-hash-instances=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `8`
- Range: `1` to `1024`

`metadata_locks_instances`

- Description: Number of fast lanes to create for metadata locks. Can be used to improve DML scalability by eliminating MDL_lock::rwlock load. Use 1 to disable MDL fast lanes. Supported MDL namespaces: BACKUP.
- Command line: `--metadata-locks-instances=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `8`

- Range: `1` to `256`
- Introduced: MariaDB 12.1

`min_examined_row_limit`

- Description: Don't write queries to slow query log that examine fewer rows than the set value. If set to `0`, the default, no row limit is used. From MariaDB 10.11.0, this is an alias for log_slow_min_examined_row_limit.
- Command line: `--min-examined-row-limit=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0-4294967295`

`mrr_buffer_size`

- Description: Size of buffer to use when using multi-range read with range access. See Multi Range Read optimization for more information.
- Command line: `--mrr-buffer-size=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `262144`
- Range `8192` to `2147483647`

`multi_range_count`

- Description: Ignored. Use mrr_buffer_size instead.
- Command line: `--multi-range-count=#`
- Default Value: `256`
- Removed: MariaDB 10.5.1

`mysql56_temporal_format`

- Description: If set (the default), MariaDB uses the MySQL 5.6 low level formats for TIME, DATETIME and TIMESTAMP instead of the MariaDB 5.3 version. The version MySQL introduced in 5.6 requires more storage, but potentially allows negative dates and has some advantages in replication. There should be no reason to revert to the old MariaDB 5.3 microsecond format. See also MDEV-10723.
- Command line: `--mysql56-temporal-format`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `ON`

`named_pipe`

- Description: On Windows systems, determines whether connections over named pipes are permitted.
- Command line: `--named-pipe`
- Scope: Global
- Dynamic: No

- Data Type: `boolean`
- Default Value: `OFF`

`net_buffer_length`

- Description: The starting size, in bytes, for the connection and thread buffers for each client thread. The size can grow to max_allowed_packet. This variable's session value is read-only. Can be set to the expected length of client statements if memory is a limitation.
- Command line: `--net-buffer-length=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `16384`
- Range: `1024` to `1048576`

`net_read_timeout`

- Description: Time in seconds the server will wait for a client connection to send more data before aborting the read. See also net_write_timeout and slave_net_timeout
- Command line: `--net-read-timeout=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `30`
- Range: `1` to `31536000`

`net_retry_count`

- Description: Permit this many retries before aborting when attempting to read or write on a communication port. On FreeBSD systems should be set higher as threads are sent internal interrupts..
- Command line: `--net-retry-count=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `10`
- Range: `1` to `4294967295`

`net_write_timeout`

- Description: Time in seconds to wait on writing a block to a connection before aborting the write. See also net_read_timeout and slave_net_timeout.
- Command line: `--net-write-timeout=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `60`
- Range: `1` upwards

`new_mode`

- Description: Used to enable new behavior in otherwise stable versions. See NEW Mode. Non-default NEW_MODE options are by design deprecated and will eventually be removed.
- Command line: `--new-mode`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `string`
- Default Value: `(empty string)`
- Valid Values: See NEW Mode for the full list.

`note_verbosity`

- Description: Verbosity level for note-warnings given to the user. Options are added in a comma-delimited string, except for `all`, which sets all options. Be aware that if the old sql_notes variable is 0, one will not get any notes. Setting `note_verbosity` to "" is the recommended way to disable notes.
  - `basic` All old notes.
  - `unusable_keys` Give warnings for unusable keys for SELECT, DELETE and UPDATE.
  - `explain` Give warnings for unusable keys for EXPLAIN.
  - `all` Enables all above options. This has to be given alone.
- Command line: `note-verbosity=value1[,value2...]`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `enumeration`
- Default Value: `basic,explain`
- Valid Values: `basic,explain,unusable_keys` or `all`.
- Introduced: MariaDB 10.6.16

`old`

- Description: Disabled by default, enabling it reverts index hints to those used before MySQL 5.1.17. Enabling may lead to replication errors. Deprecated and replaced by old_mode from MariaDB 10.9.
- Command line: `--old`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`
- Deprecated: MariaDB 10.9
- Removed: MariaDB 13.0. Use old_mode instead.

`old_alter_table`

- Description: From MariaDB 10.3.7, an alias for alter_algorithm. Prior to that, if set to `1` (`0` is default), MariaDB reverts to the non-optimized, pre-MySQL 5.1, method of processing ALTER TABLE statements. A temporary table is created, the data is copied over, and then the temporary table is renamed to the original.
- Command line: `--old-alter-table`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `enumerated` (>=MariaDB 10.3.7)

- Default Value: See alter_algorithm
- Valid Values: See alter_algorithm for the full list.
- Deprecated: MariaDB 10.3.7 (superseded by alter_algorithm)
- Removed: MariaDB 11.2.0

`old_mode`

- Description: Used for getting MariaDB to emulate behavior from an old version of MySQL or MariaDB. See OLD Mode. Fully replaces the old variable from MariaDB 10.9. Non-default OLD_MODE options are by design deprecated and will eventually be removed.
- Command line: `--old-mode`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `string`
- Default Value: `(empty string)` (>= MariaDB 13.1), `UTF8_IS_UTF8MB3` (MariaDB 10.6 to MariaDB 13.0), `(empty string)` (<= MariaDB 10.5)
- Valid Values: See OLD Mode for the full list.

`old_passwords`

- Description: If set to `1` (`0` is default), MariaDB reverts to using the mysql_old_password authentication plugin by default for newly created users and passwords, instead of the mysql_native_password authentication plugin.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`open_files_limit`

- Description: The number of file descriptors available to MariaDB. If you are getting the `Too many open files` error, then you should increase this limit. If set to 0, then MariaDB will calculate a limit based on the following:

MAX(max_connections*5, max_connections +table_open_cache*2)

MariaDB sets the limit with setrlimit. MariaDB cannot set this to exceed the hard limit imposed by the operating system. Therefore, you may also need to change the hard limit. There are a few ways to do so.

- If you are using mariadbd_safe to start `mariadbd`, then see the instructions at mariadbd_safe: Configuring the Open Files Limit.
- If you are using systemd to start `mariadbd`, then see the instructions at systemd: Configuring the Open Files Limit.
- Otherwise, you can change the hard limit for the `mysql` user account by modifying /etc/security/limits.conf. See Configuring Linux for MariaDB: Configuring the Open Files Limit for more details.
- Command line: `--open-files-limit=count`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: Autosized (see description)
- Range: `0` to `4294967295`

`optimizer_extra_pruning_depth`

- Description:If the optimizer needs to enumerate a join prefix of this size or larger, then it will try aggressively prune away the search space.
- Command line: `--optimizer-extra-pruning-depth[=#]`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `8`
- Range: `0` to `62`
- Introduced: MariaDB 10.10.1

optimizer_join_limit_pref_ratio

- Description:Controls the optimizer_join_limit_pref_ratio optimization.
- Command line: `--optimizer-join-limit-pref-ratio[=#]`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0` (Disable)
- Range: `0` to `4294967295`
- Introduced: MariaDB 10.6.20, MariaDB 10.11.10, MariaDB 11.2.6, MariaDB 11.4.4, MariaDB 11.6.2

`optimizer_max_sel_arg_weight`

- Description: This is an actively enforced maximum effective SEL_ARG tree weight limit. A SEL_ARG weight is the number of effective “ranges” hanging off this root (that is, merged tree elements are “unmerged” to count the weight). During range analysis, looking for possible index merges, SEL_ARG graphs related to key ranges in query conditions are being processed. Graphs exceeding this limit will stop keys being ‘and’ed and ’or’ed together to form a new larger SEL_ARG graph. After each ’and’ or ‘or’ process, this maximum weight limit is enforced. It enforces this limit by pruning the key part being used. This key part pruning can be used to limit/disable index merge SEL_ARG graph construction on overly long query conditions.
- Command line: `--optimizer-max-sel-arg-weight=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `32000`
- Range: `0` to `18446744073709551615`
- Introduced: MariaDB 10.5.9

`optimizer_max_sel_args`

- Description: The maximum number of SEL_ARG objects created when optimizing a range. If more objects would be needed, range scans will not be used by the optimizer.
- Command line: `--optimizer-max-sel-args=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `16000`
- Range: `0` to `4294967295`

- Introduced: MariaDB 10.6.16, MariaDB 10.10.7, MariaDB 10.11.6, MariaDB 11.0.4, MariaDB 11.1.3

`optimizer_prune_level`

- Description:Controls the heuristic(s) applied during query optimization to prune less-promising partial plans from the optimizer search space.
  - `0` : heuristics are disabled and an exhaustive search is performed
  - `1` : the optimizer will use heuristics to prune less-promising partial plans from the optimizer search space
  - `2` : tables using EQ_REF will be joined together as 'one entity' and the different combinations of these tables will not be considered (from MariaDB 10.10)
- Command line: `--optimizer-prune-level[=#]`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `2` (>= MariaDB 10.10), `1` (<= MariaDB 10.9)

`optimizer_search_depth`

- Description: Maximum search depth by the query optimizer. Smaller values lead to less time spent on execution plans, but potentially less optimal results. If set to `0`, MariaDB will automatically choose a reasonable value. Since the better results from more optimal planning usually offset the longer time spent on planning, this is set as high as possible by default. `63` is a valid value, but its effects (switching to the original find_best search) are deprecated.
- Command line: `--optimizer-search-depth[=#]`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `62`
- Range: `0` to `63`

`optimizer_selectivity_sampling_limit`

- Description: Controls number of record samples to check condition selectivity. Only used if `[optimizer_use_condition_selectivity](#pg-mization-and-tuning-system-variables-server-system-variables-e441845d) > 4.`
- Command line: `optimizer-selectivity-sampling-limit[=#]`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `100`
- Range: `10` upwards

`optimizer_switch`

- Description: A series of flags for controlling the query optimizer. See Optimizer Switch for defaults, and a comparison to MySQL.
- Command line: `--optimizer-switch=value`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `string`

- Valid Values:
  - `condition_pushdown_for_derived={on|off}`
  - `condition_pushdown_for_subquery={on|off}`
  - `condition_pushdown_from_having={on|off}`
  - `cset_narrowing={on|off}` - see Charset Narrowing Optimization (>= MariaDB 10.6.16, MariaDB 10.11.6, MariaDB 11.0.4, MariaDB 11.1.3 and MariaDB 11.2.2)
  - `default` - set all optimizations to their default values.
  - `derived_merge={on|off}` - see Derived table merge optimization
  - `derived_with_keys={on|off}` - see Derived table with key optimization
  - `duplicateweedout={on|off}`. From MariaDB 12.0.
  - `engine_condition_pushdown={on|off}`. Deprecated in MariaDB 10.1.1 as engine condition pushdown is now automatically enabled for all engines that support it.
  - `exists_to_in={on|off}` - see EXISTS-to-IN optimization
  - `extended_keys={on|off}` - see Extended Keys
  - `firstmatch={on|off}` - see First Match Strategy
  - `hash_join_cardinality={on|off}` - see hash_join_cardinality-optimizer_switch-flag (>= MariaDB 11.0.2, MariaDB 10.11.3, MariaDB 10.6.13)
  - `index_condition_pushdown={on|off}` - see Index Condition Pushdown
  - `index_merge={on|off}`
  - `index_merge_intersection={on|off}`
  - `index_merge_sort_intersection={on|off}` - more details
  - `index_merge_sort_union={on|off}`
  - `index_merge_union={on|off}`
  - `in_to_exists={on|off}` - see IN-TO-EXISTS transformation
  - `join_cache_bka={on|off}` - see Block-Based Join Algorithms
  - `join_cache_hashed={on|off}` - see Block-Based Join Algorithms
  - `join_cache_incremental={on|off}` - see Block-Based Join Algorithms
  - `loosescan={on|off}` - see LooseScan strategy
  - `materialization={on|off}` - Semi-join and non semi-join materialization.
  - `mrr={on|off}` - see Multi Range Read optimization
  - `mrr_cost_based={on|off}` - see Multi Range Read optimization
  - `mrr_sort_keys={on|off}` - see Multi Range Read optimization
  - `not_null_range_scan={on|off}` - see not_null_range_scan optimization (>= MariaDB 10.5.0)
  - `optimize_join_buffer_size={on|off}` - see Block-Based Join Algorithms
  - `orderby_uses_equalities={on|off}` - if not set, the optimizer ignores equality propagation. See MDEV-8989.
  - `outer_join_with_cache={on|off}` - see Block-Based Join Algorithms
  - `partial_match_rowid_merge={on|off}` - see Non-semi-join subquery optimizations
  - `partial_match_table_scan={on|off}` - see Non-semi-join subquery optimizations
  - `reorder_outer_joins` - see reorder_outer_joins (MariaDB 12.3)
  - `rowid_filter={on|off}` - see Rowid Filtering Optimization
  - `sargable_casefold={on|off}` (>= MariaDB 11.3.0)
  - `semijoin={on|off}` - see Semi-join subquery optimizations
  - `semijoin_with_cache={on|off}` - see Block-Based Join Algorithms
  - `split_materialized={on|off}`

- `subquery_cache={on|off}` - see subquery cache.
- `table_elimination={on|off}` - see Table Elimination User Interface

`optimizer_record_context`

- Description: Controls storing of optimizer context of all tables that are referenced in a query.
- Command line: `--optimizer-record-context{=0|1}`
- Scope: Session
- Dynamic: Yes
- Data Type: boolean
- Default Value: `OFF`
- Introduced: MariaDB 12.1

`optimizer_trace`

- Description: Controls tracing of the optimizer: optimizer_trace=option=val[,option=val…], where option is one of {enabled} and val is one of {on, off, default}
- Command line: `--optimizer-trace=value`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `enum`
- Default Value: `enabled=off`
- Valid Values: `enabled={on|off|default}`

`optimizer_trace_max_mem_size`

- Description: Limits the memory used while tracing a query by specifying the maximum allowed cumulated size, in bytes, of stored optimizer traces.
- Command line: `--optimizer-trace-max-mem-size=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `1048576`
- Range: `1` to `18446744073709551615`

`optimizer_use_condition_selectivity`

- Description: Controls which statistics can be used by the optimizer when looking for the best query execution plan. In most cases, the default value, `4` will be suitable. However, if you are hitting some of the rare cases where this does not work well (see MDEV-23707), you can usually work around this by setting this variable to `1`.
  - `1` Use selectivity of predicates as in MariaDB 5.5.
  - `2` Use selectivity of all range predicates supported by indexes.
  - `3` Use selectivity of all range predicates estimated without histogram.
  - `4` Use selectivity of all range predicates estimated with histogram.
  - `5` Additionally use selectivity of certain non-range predicates calculated on record sample.
- Command line: `--optimizer-use-condition-selectivity=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`

- Default Value: `4`
- Range: `1` to `5`

`pid_file`

- Description: Full path of the process ID file. If –log-basename is also set, `pid_file` should be placed after in the config files. Later settings override earlier settings, so `log-basename` will override any earlier log file name settings.
- Command line: `--pid-file=file_name`
- Scope: Global
- Dynamic: No
- Data Type: `file name`

`plugin_dir`

- Description: Path to the plugin directory. For security reasons, either make sure this directory can only be read by the server, or set secure_file_priv.
- Command line: `--plugin-dir=path`
- Scope: Global
- Dynamic: No
- Data Type: `directory name`
- Default Value: `BASEDIR/lib/plugin`

`plugin_maturity`

- Description: The lowest acceptable plugin maturity. MariaDB will not load plugins less mature than the specified level.
- Command line: `--plugin-maturity=level`
- Scope: Global
- Dynamic: No
- Type: enum
- Default Value: One less than the server maturity
- Valid Values: `unknown`, `experimental`, `alpha`, `beta`, `gamma`, `stable`

`port`

- Description: Port to listen for TCP/IP connections. If set to `0`, will default to, in order of preference, my.cnf, the `MYSQL_TCP_PORT` environment variable, /etc/services, built-in default (3306).
- Command line: `--port=#`, `-P`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `3306`
- Range: `0` to `65535`

`preload_buffer_size`

- Description: Size in bytes of the buffer allocated when indexes are preloaded.
- Command line: `--preload-buffer-size=#`
- Scope: Global, Session

- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `32768`
- Range: `1024` to `1073741824`

`profiling`

- Description: If set to `1` (`0` is default), statement profiling will be enabled. See SHOW PROFILES() and SHOW PROFILE().
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`profiling_history_size`

- Description: Number of statements about which profiling information is maintained. If set to `0`, no profiles are stored. See SHOW PROFILES.
- Command line: `--profiling-history-size=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `15`
- Range: `0` to `100`

`progress_report_time`

- Description: Time in seconds between sending progress reports to the client for time-consuming statements. If set to `0`, progress reporting will be disabled.
- Command line: `--progress-report-time=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `5`
- Range: `0` to `4294967295`

`protocol_version`

- Description: The version of the client/server protocol used by the MariaDB server.
- Command line: None
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `10`
- Range: `0` to `4294967295`

`proxy_protocol_networks`

- Description: Enable proxy protocol for these source networks. The syntax is a comma separated list of IPv4 and IPv6 networks. If the network doesn't contain a mask, it is considered to be a single host. "*" represents all

networks and must be the only directive on the line. String “localhost” represents non-TCP local connections (Unix domain socket, Windows named pipe or shared memory). See Proxy Protocol Support.

- Command line: `--proxy-protocol-networks=value`
- Scope: Global
- Dynamic: Yes
- Data Type: `string`
- Default Value: (empty)

`proxy_user`

- Description: Set to the proxy user account name if the current client is a proxy, else `NULL`.
- Scope: Session
- Dynamic: No
- Data Type: `string`

`pseudo_slave_mode`

- Description: For internal use by the server.
- Scope: Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `OFF`

`pseudo_thread_id`

- Description: For internal use only.
- Scope: Session
- Dynamic: Yes
- Data Type: `numeric`

`query_alloc_block_size`

- Description: Size in bytes of the extra blocks allocated during query parsing and execution (after query_prealloc_size is used up).
- Command line: `--query-alloc-block-size=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `BIGINT UNSIGNED`
- Default Value:
  - >= MariaDB 11.4.5, MariaDB 10.11.11, MariaDB 10.6.22: `32768`
  - <= MariaDB 11.4.4, MariaDB 10.11.10, MariaDB 10.6.21: `16384`
- Range: `1024` to `4294967295`
- Block size: `1024`

`query_cache_limit`

- Description: Size in bytes for which results larger than this are not stored in the query cache.
- Command line: `--query-cache-limit=#`
- Scope: Global
- Dynamic: Yes

- Data Type: `numeric`
- Default Value: `1048576` (1MB)
- Range: `0` to `4294967295`

`query_cache_min_res_unit`

- Description: Minimum size in bytes of the blocks allocated for query cache results.
- Command line: `--query-cache-min-res-unit=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `4096` (4KB)
- Range - 32 bit: `1024` to `4294967295`
- Range - 64 bit: `1024` to `18446744073709547520`

`query_cache_size`

- Description: Size in bytes available to the query cache. About 40KB is needed for query cache structures, so setting a size lower than this will result in a warning. `0`, the default before MariaDB 10.1.7, effectively disables the query cache.

Warning: Starting from MariaDB 10.1.7, query_cache_type is automatically set to ON if the server is started with the query_cache_size set to a non-zero (and non-default) value. This will happen even if query_cache_type is explicitly set to OFF in the configuration.

- Command line: `--query-cache-size=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `1M` (although frequently given a default value in some setups)
- Valid Values: `0` upwards in units of 1024.

`query_cache_strip_comments`

- Description: If set to `1` (`0` is default), the server will strip any comments from the query before searching to see if it exists in the query cache. Multiple space, line feeds, tab and other white space characters will also be removed.
- Command line: `query-cache-strip-comments`
- Scope: Session, Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`query_cache_type`

- Description: If set to `0`, the query cache is disabled (although a buffer of query_cache_size bytes is still allocated). If set to `1` all SELECT queries will be cached unless SQL_NO_CACHE is specified. If set to `2` (or `DEMAND`), only queries with the SQL CACHE clause will be cached. Note that if the server is started with the query cache disabled, it cannot be enabled at runtime.

Warning: Starting from MariaDB 10.1.7, query_cache_type is automatically set to ON if the server is started with the query_cache_size set to a non-zero (and non-default) value. This will happen even if query_cache_type is explicitly

set to OFF in the configuration.

- Command line: `--query-cache-type=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `enumeration`
- Default Value: `OFF`
- Valid Values: `0` or `OFF`, `1` or `ON`, `2` or `DEMAND`

`query_cache_wlock_invalidate`

- Description: If set to `0`, the default, results present in the query cache will be returned even if there's a write lock on the table. If set to `1`, the client will first have to wait for the lock to be released.
- Command line: `--query-cache-wlock-invalidate`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`query_prealloc_size`

- Description: Size in bytes of the persistent buffer for query parsing and execution, allocated on connect and freed on disconnect. Increasing may be useful if complex queries are being run, as this will reduce the need for more memory allocations during query operation. See also query_alloc_block_size.
- Command line: `--query-prealloc-size=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value:
  - >= MariaDB 11.4.5, MariaDB 10.11.11, MariaDB 10.6.22: `32768`
  - <= MariaDB 11.4.4, MariaDB 10.11.10, MariaDB 10.6.21: `24576`
- Range: `1024` to `4294967295`

`rand_seed1`

- Description: `rand_seed1` and `rand_seed2` facilitate replication of the RAND() function. The master passes the value of these to the slaves so that the random number generator is seeded in the same way, and generates the same value, on the slave as on the master.
- Command line: None
- Scope: Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: Varies
- Range: `0` to `18446744073709551615`

`rand_seed2`

- Description: See rand_seed1.

`range_alloc_block_size`

- Description: Size in bytes of blocks allocated during range optimization. The unit size in 1024.
- Command line: `--range-alloc-block-size=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `4096`
- Range - 32 bit: `4096` to `4294967295`
- Range - 64 bit: `4096` to `18446744073709547520`

`read_buffer_size`

- Description: Each thread performing a sequential scan (for MyISAM, Aria and MERGE tables) allocates a buffer of this size in bytes for each table scanned. Increase if you perform many sequential scans. If not in a multiple of 4KB, will be rounded down to the nearest multiple. Also used in ORDER BY's for caching indexes in a temporary file (not temporary table), for caching results of nested queries, for bulk inserts into partitions, and to determine the memory block size of MEMORY tables.
- Command line: `--read-buffer-size=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `131072`
- Range: `8192` to `2147479552`

`read_only`

> **CURRENT**
>
> - Description: Do not allow changes to non-temporary tables. Options are: `OFF` — changes allowed; `ON` — Disallow changes for users without the `READ ONLY ADMIN` privilege; `NO_LOCK` — Additionally disallows `LOCK TABLES` and `SELECT ... IN SHARE MODE`; `NO_LOCK_NO_ADMIN` — Disallows also for users with `READ_ONLY ADMIN` privilege. Replication (slave) threads are not affected by this option.
> - Command line: `--read-only`
> - Scope: Global
> - Dynamic: Yes
> - Data Type: `enum`
> - Default Value: `OFF`
> - Valid values: `OFF`, `ON`, `NO_LOCK`, `NO_LOCK_NO_ADMIN`
>
> **< 12.0**
>
> - Description: When set to `1` (`0` is default), no updates are permitted except from users with the SUPER privilege or, from MariaDB 10.5.2, the READ ONLY ADMIN privilege, or replica servers updating from a primary. The `read_only` variable is useful for replica servers to ensure no updates are accidentally made outside of what are performed on the primary. Inserting rows to log tables, updates to temporary tables and OPTIMIZE TABLE or ANALYZE TABLE statements are excluded from this limitation. If `read_only` is set to `1`, then the SET PASSWORD statement is limited only to users with the SUPER privilege (<= MariaDB 10.5.1) or READ ONLY ADMIN privilege (>= MariaDB 10.5.2). Attempting to set this variable to `1` will fail if the current session has table locks or transactions pending, while if other sessions hold table locks, the statement will wait until these locks are released before completing. While the attempt to set `read_only` is waiting, other requests

> for table locks or transactions will also wait until `read_only` has been set. See Read-Only Replicas for more. From MariaDB 10.5.2, the READ_ONLY ADMIN privilege will allow users granted that privilege to perform writes, even if the `read_only` variable is set. In earlier versions, and until MariaDB 10.11.0, users with the SUPER can perform writes while this variable is set.
> - Command line: `--read-only`
> - Scope: Global
> - Dynamic: Yes
> - Data Type: `boolean`
> - Default Value: `OFF`

`read_rnd_buffer_size`

- Description: Size in bytes of the buffer used when reading rows from a MyISAM table in sorted order after a key sort. Larger values improve ORDER BY performance, although rather increase the size by SESSION where the need arises to avoid excessive memory use.
- Command line: `--read-rnd-buffer-size=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `262144`
- Range: `8200` to `2147483647`

`redirect_url`

- Description: URL of another server to redirect clients to. Format should be `{mysql,mariadb}://host [:port]`. Empty string means no redirection. For example, `set global redirect_url="mysql://mariadb.org:12345"`. See Connection Redirection Mechanism in the MariaDB Client/Server Protocol.
- Command line: `--redirect_url=val`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `string`
- Default Value: Empty
- Introduced: MariaDB 11.3.0

`require_secure_transport`

- Description: When this option is enabled, connections attempted using insecure transport will be rejected. Secure transports are SSL/TLS, Unix sockets or named pipes. Note that per-account requirements take precedence.
- Command line: `--require-secure-transport[={0|1}]`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`
- Introduced: MariaDB 10.5.2

`rowid_merge_buff_size`

- Description: The maximum size in bytes of the memory available to the Rowid-merge strategy. See Non-semi-join subquery optimizations for more information.
- Command line: `--rowid-merge-buff-size=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `8388608`
- Range: `0` to `2147483647`

`rpl_recovery_rank`

- Description: Unused.
- Removed: MariaDB 10.1.2

`safe_show_database`

- Description: This variable was removed in MariaDB 5.5 and has been replaced by the more flexible SHOW DATABASES privilege.
- Command line: `--safe-show-database` (until MySQL 4.1.1)
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Removed: MariaDB 5.5

`secure_auth`

- Description: Connections will be blocked if they use the mysql_old_password authentication plugin. The server will also fail to start if the privilege tables are in the old, pre-MySQL 4.1 format. `secure_auth=0` was deprecated in MariaDB 10.6.17, MariaDB 10.11.7, MariaDB 11.0.5, MariaDB 11.1.4, MariaDB 11.2.3.
- Command line: `--secure-auth`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `ON`
- Removed: MariaDB 13.0. The `secure_auth` system variable and the `--secure-auth` server option were removed. The protection they provided (blocking connections that use the mysql_old_password authentication plugin, and refusing to start when the privilege tables are in the old, pre-MySQL 4.1 format) is now always enforced and can no longer be disabled.

`secure_file_priv`

- Description: LOAD DATA, SELECT … INTO and LOAD FILE() will only work with files in the specified path. If not set, the default, or set to empty string, the statements will work with any files that can be accessed.
- Command line: `--secure-file-priv=path`
- Scope: Global
- Dynamic: No
- Data Type: `path name`
- Default Value: None

`secure_timestamp`

- Description: Restricts direct setting of a session timestamp. Possible levels are:
  - YES - timestamp cannot deviate from the system clock. Intended to prevent tampering with system versioning history. Should not be used on replicas, as when a value based on the timestamp is inserted in statement mode, discrepancies can occur.
  - REPLICATION - replication thread can adjust timestamp to match the primary's
  - SUPER - a user with this privilege and a replication thread can adjust timestamp
  - NO - historical behavior, anyone can modify session timestamp
- Command line: `--secure-timestamp=value`
- Scope: Global
- Dynamic: No
- Data Type: `enum`
- Default Value: `NO`

`server_uid`

- Description: Automatically calculated server unique id hash. Added to the error log to allow one to verify if error reports are from the same server. UID is a base64-encoded SHA1 hash of the MAC address of one of the interfaces, and the tcp port that the server is listening on.
- Command line: None
- Scope: Global
- Dynamic: No
- Data Type: `varchar`
- Default Value: None
- Introduced: MariaDB 10.5.26, MariaDB 10.6.19, MariaDB 10.11.9, MariaDB 11.1.6, MariaDB 11.2.5, MariaDB 11.4.3, MariaDB 11.5.2, MariaDB 11.6.1

`session_track_schema`

- Description: Whether to track changes to the default schema within the current session.
- Command line: `--session-track-schema={0|1}`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `ON`

`session_track_state_change`

- Description: Whether to track changes to the session state.
- Command line: `--session-track-state-change={0|1}`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`session_track_system_variables`

- Description: Comma-separated list of session system variables for which to track changes. For compatibility with MySQL defaults, this variable should be set to "autocommit, character_set_client, character_set_connection,

character_set_results, time_zone". The `*` character tracks all session variables.

- Command line: `--session-track-system-variables=value`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `string`
- Default Value:
  - > = MariaDB 11.3: `autocommit,character_set_client,character_set_connection,character_set_results,redirect_url,time_zone`
  - <= MariaDB 11.2: `autocommit, character_set_client, character_set_connection, character_set_results, time_zone`

`session_track_transaction_info`

- Description: Track changes to the transaction attributes. OFF to disable; STATE to track just transaction state (Is there an active transaction? Does it have any data? etc.); CHARACTERISTICS to track transaction state and report all statements needed to start a transaction with the same characteristics (isolation level, read only/read write,snapshot - but not any work done / data modified within the transaction).
- Command line: `--session-track-transaction-info=value`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `enum`
- Default Value: `OFF`
- Valid Values: `OFF`, `STATE`, `CHARACTERISTICS`

`shared_memory`

- Description: Windows only, determines whether the server permits shared memory connections. See also shared_memory_base_name.
- Scope: Global
- Dynamic: No

`shared_memory_base_name`

- Description: Windows only, specifies the name of the shared memory to use for shared memory connection. Mainly used when running more than one instance on the same physical machine. By default the name is `MYSQL` and is case sensitive. See also shared_memory.
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value: `MYSQL`

`shutdown_wait_for_slaves`

- Description: When `ON, SHUTDOWN` command runs with implicit `WAIT FOR ALL SLAVES` option. That is, when running `SHUTDOWN`, before killing the binary log dump threads, the server will first kill all client threads and send all binary log events to all connected replicas.
- Scope: Global
- Dynamic: No

- Data Type: `Boolean`
- Default Value: `OFF`

`skip_external_locking`

- Description: If this system variable is set, then some kinds of external table locks will be disabled for some storage engines.
  - If this system variable is set, then the MyISAM storage engine will not use file-based locks. Otherwise, it will use the fcntl() function with the `F_SETLK` option to get file-based locks on Unix, and it will use the LockFileEx() function to get file-based locks on Windows.
  - If this system variable is set, then the Aria storage engine will not lock a table when it decrements the table's in-file counter that keeps track of how many connections currently have the table open. See MDEV-19393 for more information.
  - Note that command line option name is the opposite of the variable name, and the value is the opposite too. `--external-locking=1` means `@@skip_external_locking=0`, and vice versa.
- Command line: `--external-locking`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `1` (for the variable, that is `0` for the command line option)

`skip_grant_tables`

- Description: Start without grant tables. This gives all users FULL ACCESS to all tables. Before MariaDB 10.10, available as an option only. Use mariadb-admin flush-privileges, mariadb-admin reload or FLUSH PRIVILEGES to resume using the grant tables.
- Command line: `--skip-grant-tables`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`
- Introduced: MariaDB 10.10

`skip_name_resolve`

- Description: If set to `ON` (`OFF` is the default), only IP addresses are used for connections. Host names are not resolved. All host values in the GRANT tables must be IP addresses (or localhost). Some container configs explicitly set `skip_name_resolve` to `ON`, rather than leave it as the default, `OFF`.
- Command line: `--skip-name-resolve`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`

`skip_networking`

- Description: If set to 1, (0 is the default), the server does not listen for TCP/IP connections. All interaction with the server will be through socket files (Unix) or named pipes or shared memory (Windows). It's recommended to use this option if only local clients are permitted to connect to the server.
- Command line: `--skip-networking`

- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `0`

`skip_show_database`

- Description: If set to 1, (0 is the default), only users with the SHOW DATABASES privilege can use the SHOW DATABASES statement to see all database names.
- Command line: `--skip-show-database`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `0`

`slow_launch_time`

- Description: Time in seconds. If a thread takes longer than this to launch, the `slow_launch_threads` server status variable is incremented.
- Command line: `--slow-launch-time=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `2`

`slow_query_log`

- Description: If set to 0, the default unless the –slow-query-log option is used, the slow query log is disabled, while if set to 1 (both global and session variables), the slow query log is enabled. From MariaDB 10.11.0, an alias for log_slow_query.
- Command line: `--slow-query-log`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Data Type: `boolean`
- Default Value: `0`
- See also: See log_output to see how log files are written. If that variable is set to `NONE`, no logs will be written even if slow_query_log is set to `1`.

`slow_query_log_file`

- Description: Name of the slow query log file. From MariaDB 10.11, an alias for log_slow_query_file. If –log-basename is also set, `slow_query_log_file` should be placed after in the config files. Later settings override earlier settings, so `log-basename` will override any earlier log file name settings.
- Command line: `--slow-query-log-file=file_name`
- Scope: Global
- Dynamic: Yes
- Data Type: `file name`
- Default Value: `host_name-slow.log`

`socket`

- Description: On Unix-like systems, this is the name of the socket file used for local client connections, by default `/tmp/mysql.sock`, often changed by the distribution, for example `/var/lib/mysql/mysql.sock`. On Windows, this is the name of the named pipe used for local client connections, by default `MySQL`. On Windows, this is not case-sensitive.
- Command line: `--socket=name`
- Scope: Global
- Dynamic: No
- Data Type: `file name`
- Default Value: `/tmp/mysql.sock` (Unix), `MySQL` (Windows)

`sort_buffer_size`

- Description: Each session performing a sort allocates a buffer with this amount of memory. Not specific to any storage engine. If the status variable sort_merge_passes is too high, you may need to look at improving your query indexes or increasing this. Consider reducing where there are many small sorts, such as OLTP, and increasing where needed by session. 16k is a suggested minimum.
- Command line: `--sort-buffer-size=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `number`
- Default Value: `2M (2097152)` (some distributions increase the default)

`sql_auto_is_null`

- Description: If set to 1, the query `SELECT * FROM table_name WHERE auto_increment_column IS NULL` will return an auto-increment that has just been successfully inserted, the same as the LAST_INSERT_ID() function. Some ODBC programs make use of this IS NULL comparison.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `0`

`sql_big_selects`

- Description: If set to 0, MariaDB will not perform large SELECTs. See max_join_size for details. If max_join_size is set to anything but DEFAULT, sql_big_selects is automatically set to 0. If sql_big_selects is again set, max_join_size will be ignored.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `1`

`sql_big_tables`

- Description: Old variable, which if set to 1, allows large result sets by saving all temporary sets to disk, avoiding 'table full' errors. No longer needed, as the server now handles this automatically.
  - This is a synonym for big_tables.
- Command line: `--sql-big-tables`
- Scope: Global, Session

- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `0`
- Removed: MariaDB 10.0

`sql_buffer_result`

- Description: If set to 1 (0 is default), results from SELECT statements are always placed into temporary tables. This can help the server when it takes a long time to send the results to the client by allowing the table locks to be freed early.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `0`

`sql_if_exists`

- Description: If set to 1, adds an implicit IF EXISTS to ALTER, RENAME and DROP of TABLES, VIEWS, FUNCTIONS and PACKAGES. This variable is mainly used in replication to tag DDLs that can be ignored on the slave if the target table doesn't exist.
- Command line: `--sql-if-exists[={0|1}]`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`
- Introduced: MariaDB 10.5.2

`sql_log_off`

- Description: If set to 1 (0 is the default), no logging to the general query log is done for the client. Only clients with the SUPER privilege can update this variable.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `0`

`sql_log_update`

- Description: Removed. Use sql_log_bin instead.
- Removed: MariaDB/MySQL 5.5

`sql_low_priority_updates`

- Description: If set to 1 (0 is the default), for storage engines that use only table-level locking (Aria, MyISAM, MEMORY and MERGE), all INSERTs, UPDATEs, DELETEs and LOCK TABLE WRITEs will wait until there are no more SELECTs or LOCK TABLE READs pending on the relevant tables. Set this to 1 if reads are prioritized over writes.
  - This is a synonym for low_priority_updates.
- Command line: `--sql-low-priority-updates`
- Scope: Global, Session
- Dynamic: Yes

- Data Type: `boolean`
- Default Value: `0`
- Removed: MariaDB 10.0

`sql_max_join_size`

- Description: Synonym for max_join_size, the preferred name.
- Deprecated: MariaDB 5.5
- Removed: MariaDB 10.0

`sql_mode`

- Description: Sets the SQL Mode. Multiple modes can be set, separated by a comma.
- Command line: `--sql-mode=value[,value[,value...]]`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `string`
- Default Value:
  - `STRICT_TRANS_TABLES,ERROR_FOR_DIVISION_BY_ZERO,NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION`
- Valid Values: See SQL Mode for the full list.

`sql_notes`

- Description: If set to 1, the default, warning_count is incremented each time a Note warning is encountered. If set to 0, Note warnings are not recorded. mariadb-dump has outputs to set this variable to 0 so that no unnecessary increments occur when data is reloaded. See also note_verbosity, which defines which notes should be given. The recommended way, as of MariaDB 10.6.16, to disable notes is to set `note_verbosity` to ““.
- Command line: None
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `1`

`sql_quote_show_create`

- Description: If set to 1, the default, the server will quote identifiers for SHOW CREATE DATABASE, SHOW CREATE TABLE and SHOW CREATE VIEW statements. Quoting is disabled if set to 0. Enable to ensure replication works when identifiers require quoting.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `1`

`sql_safe_updates`

- Description: If set to 1, UPDATEs and DELETEs must be executed by using an index (simply mentioning an indexed column in a WHERE clause is not enough, optimizer must actually use it) or they must mention an indexed column and specify a LIMIT clause. Otherwise a statement will be aborted. Prevents the common mistake of accidentally deleting or updating every row in a table. Until MariaDB 10.3.11, could not be set as a command-line option or in my.cnf.

- Command line: `--sql-safe-updates[={0|1}]`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`sql_select_limit`

- Description: Maximum number of rows that can be returned from a SELECT query. Default is the maximum number of rows permitted per table by the server, usually 232-1 or 264-1. Can be restored to the default value after being changed by assigning it a value of DEFAULT. If a SELECT has a LIMIT clause, the LIMIT takes precedence over the value of the variable.
- Command line: None
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `18446744073709551615`

`sql_warnings`

- Description: If set to 1, single-row INSERTs will produce a string containing warning information if a warning occurs.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF (0)`

`storage_engine`

- Description: See default_storage_engine.
- Deprecated: MariaDB 5.5
- Removed: MariaDB 12.0

`standard_compliant_cte`

- Description: Allow only standard-compliant common table expressions. Prior to MariaDB 10.2.4, this variable was named `standards_compliant_cte`.
- Command line: `--standard-compliant-cte={0|1}`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `ON`

`stored_program_cache`

- Description: Limit to the number of stored routines held in the stored procedures and stored functions caches. Each time a stored routine is executed, this limit is first checked, and if the number held in the cache exceeds this, that cache is flushed and memory freed.
- Command line: `--stored-program-cache=#`
- Scope: Global
- Dynamic: Yes

- Data Type: `numeric`
- Default Value: `256`
- Range: `256` to `524288`

`strict_password_validation`

- Description: When password validation plugins are enabled, reject passwords that cannot be validated (passwords specified as a hash). This excludes direct updates to the privilege tables.
- Command line: `--strict-password-validation`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `ON`

`sync_frm`

- Description: If set to 1, the default, each time a non-temporary table is created, its .frm definition file is synced to disk. Fractionally slower, but safer in case of a crash.
- Command line: `--sync-frm`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `TRUE`

`system_time_zone`

- Description: The system time zone is determined when the server starts. The system time zone is usually read from the operating system's environment but can be overridden by setting the 'TZ' environment variable before starting the server. See Time Zones: System Time Zone for the various ways to change the system time zone. This variable is not the same as the time_zone system variable, which is the variable that actually controls a session's active time zone. The system time zone is used for a session when `time_zone` is set to the special value `SYSTEM`.
- Scope: Global
- Dynamic: No
- Data Type: `string`

`table_definition_cache`

- Description: Number of table definitions that can be cached. Table definitions are taken from the .frm files, and if there are a large number of tables increasing the cache size can speed up table opening. Unlike the table_open_cache, as the table_definition_cache doesn't use file descriptors and is much smaller.
- Command line: `--table-definition-cache=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `400`
- Range: `400` to `2097152`

`table_lock_wait_timeout`

- Description: Unused, and removed.

- Command line: `--table-lock-wait-timeout=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `50`
- Range: `1` to `1073741824`
- Removed: MariaDB 5.5

`table_open_cache`

- Description: Maximum number of open tables cached in one table cache instance. See Optimizing table_open_cache for suggestions on optimizing. Increasing table_open_cache increases the number of file descriptors required.
- Command line: `--table-open-cache=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `2000`
- Range:
  - `1` to `1048576` (1024K)

`table_open_cache_instances`

- Description: This system variable specifies the maximum number of table cache instances. MariaDB Server initially creates just a single instance. However, whenever it detects contention on the existing instances, it will automatically create a new instance. When the number of instances has been increased due to contention, it does not decrease again. The default value of this system variable is `8`, which is expected to handle up to 100 CPU cores. If your system is larger than this, then you may benefit from increasing the value of this system variable.
  - Depending on the ratio of actual available file handles, and table_open_cache size, the max. instance count may be auto adjusted to a lower value on server startup.
  - The implementation and behavior of this feature is different than the same feature in MySQL 5.6.
  - See Optimizing table_open_cache: Automatic Creation of New Table Open Cache Instances for more information.
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `8` (>= MariaDB 10.2.2)
- Range: `1` to `64`

`table_type`

- Description: Removed and replaced by storage_engine. Use default_storage_engine instead.

`tcp_keepalive_interval`

- Description: The interval, in seconds, between when successive keep-alive packets are sent if no acknowledgement is received. If set to 0, the system dependent default is used.
- Command line: `--tcp-keepalive-interval=#`
- Scope: Global

- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `2147483`

`tcp_keepalive_probes`

- Description: The number of unacknowledged probes to send before considering the connection dead and notifying the application layer. If set to 0, a system dependent default is used.
- Command line: `--tcp-keepalive-probes=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `2147483`

`tcp_keepalive_time`

- Description: Timeout, in seconds, with no activity until the first TCP keep-alive packet is sent. If set to 0, a system dependent default is used.
- Command line: `--tcp-keepalive-time=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `2147483`

`tcp_nodelay`

- Description: Set the TCP_NODELAY option (disable Nagle's algorithm) on socket.
- Command line: `--tcp-nodelay={0|1}`
- Scope: Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `1`

`thread_cache_size`

- Description: Number of threads server caches for reuse. If this limit hasn't been reached, when a client disconnects, its threads are put into the cache and reused where possible. In MariaDB 10, MariaDB 5.5, and newer, the threads are freed after 5 minutes of idle time. Normally this setting has little effect, as the other aspects of the thread implementation are more important, but increasing it can help servers with high volumes of connections per second so that most can use a cached, rather than a new, thread. The cache miss rate can be calculated as the server status variables threads_created/connections. If the thread pool is active, `thread_cache_size` is ignored. If `thread_cache_size` is set to greater than the value of max_connections, `thread_cache_size` will be set to the max_connections value.
- Command line: `--thread-cache-size=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`

- Default Value: `256` (adjusted if thread pool is active)
- Range: `0` to `16384`

`thread_concurrency`

- Description: Allows applications to give the system a hint about the desired number of threads. Specific to Solaris only, invokes thr_setconcurrency(). Deprecated and has no effect from MariaDB 5.5.
- Command line: `--thread-concurrency=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `10`
- Range: `1` to `512`
- Deprecated: MariaDB 5.5
- Removed: MariaDB 10.5.1

`thread_stack`

- Description: Stack size for each thread. If set too small, limits recursion depth of stored procedures and complexity of SQL statements the server can handle in memory. Also affects limits in the crash-me test.
- Command line: `--thread-stack=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value:
  - `299008`
- Range: `131072` to `18446744073709551615`

`time_format`

- Description: Unused.
- Removed: MariaDB 11.3.0

`time_zone`

- Description: The global value determines the default time zone for sessions that connect. The session value determines the session's active time zone. When it is set to `SYSTEM`, the session's time zone is determined by the system_time_zone system variable.
- Command line: `--default-time-zone=string`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `string`
- Default Value: `SYSTEM`

`timed_mutexes`

- Description: Determines whether InnoDB mutexes are timed. `OFF`, the default, disables mutex timing, while `ON` enables it. See also SHOW ENGINE for more on mutex statistics. Deprecated and has no effect.
- Command line: `--timed-mutexes`
- Scope: Global

- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`
- Deprecated: MariaDB 5.5.39
- Removed: MariaDB 10.5.1

`timestamp`

- Description: Sets the time for the client. This will affect the result returned by the NOW() function, not the SYSDATE() function, unless the server is started with the –sysdate-is-now option, in which case SYSDATE becomes an alias of NOW, and will also be affected. Also used to get the original timestamp when restoring rows from the binary log.
- Scope: Session
- Dynamic: Yes
- Valid Values: `timestamp_value` (Unix epoch timestamp, not MariaDB timestamp), `DEFAULT`

`tmp_disk_table_size`

- Description: Max size for data for an internal temporary on-disk MyISAM or Aria table. These tables are created as part of complex queries when the result doesn't fit into the memory engine. You can set this variable if you want to limit the size of temporary tables created in your temporary directory tmpdir.
- Command line: `--tmp-disk-table-size=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `18446744073709551615` (max unsigned integer, no limit)
- Range: `1024` to `18446744073709551615`

`tmp_memory_table_size`

- Description: An alias for tmp_table_size.
- Command line: `--tmp-memory-table-size=#`

`tmp_table_size`

- Description: The largest size for temporary tables in memory (not MEMORY tables) although if max_heap_table_size is smaller the lower limit will apply. You can see if it's necessary to increase by comparing the status variables `Created_tmp_disk_tables` and `Created_tmp_tables` to see how many temporary tables out of the total created needed to be converted to disk. Often complex GROUP BY queries are responsible for exceeding the limit. Defaults may be different on some systems, see for example Differences in MariaDB in Debian. tmp_memory_table_size is an alias.
- Command line: `--tmp-table-size=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `16777216` (16MB)
- Range:
  - `1024` to `4294967295` (< MariaDB 10.5)
  - `0` to `4294967295` (>= MariaDB 10.5.0)

`tmpdir`

- Description: Directory for storing temporary tables and files. Can specify a list (separated by semicolons in Windows, and colons in Unix) that will then be used in round-robin fashion. This can be used for load balancing across several disks. Note that if the server is a replication replica, and slave_load_tmpdir, which overrides `tmpdir` for replicas, is not set, you should not set `tmpdir` to a directory that is cleared when the machine restarts, or else replication may fail.
- Command line: `--tmpdir=path` or `-t path`
- Scope: Global
- Dynamic: No
- Type: directory name/s
- Default:
  - `$TMPDIR` (environment variable) if set
  - otherwise `$TEMP` if set and on Windows
  - otherwise `$TMP` if set and on Windows
  - otherwise, `P_tmpdir` (`"/tmp"`) or `C:\TEMP` (unless overridden during build time)

`transaction_alloc_block_size`

- Description: Size in bytes to increase the memory pool available to each transaction when the available pool is not large enough. See transaction_prealloc_size.
- Command line: `--transaction-alloc-block-size=#`
- Scope: Global, Session
- Dynamic: Yes
- Type: numeric
- Default Value: `8192`
- Range: `1024` to `134217728` (128M)
- Block Size: `1024`

`transaction_isolation`

- Description: The transaction isolation level. See also SET TRANSACTION ISOLATION LEVEL. Introduced in MariaDB 11.1.1 to replace the tx_isolation system variable and align the option and the system variable name.
- Command line: `--transaction-isolation=name`
- Scope: Global, Session
- Dynamic: Yes
- Type: enumeration
- Default Value: `REPEATABLE-READ`
- Valid Values: `READ-UNCOMMITTED`, `READ-COMMITTED`, `REPEATABLE-READ`, `SERIALIZABLE`
- Introduced: MariaDB 11.1.1

`transaction_prealloc_size`

- Description: Initial size of a memory pool available to each transaction for various memory allocations. If the memory pool is not large enough for an allocation, it is increased by transaction_alloc_block_size bytes, and truncated back to transaction_prealloc_size bytes when the transaction is completed. If set large enough to contain all statements in a transaction, extra malloc() calls are avoided.
- Command line: `--transaction-prealloc-size=#`
- Scope: Global, Session
- Dynamic: Yes

- Type: numeric
- Default Value: `4096`
- Range: `1024` to `134217728` (128M)
- Block Size: `1024`

`transaction_read_only`

- Description: Default transaction access mode. If set to `OFF`, the default, access is read/write. If set to `ON`, access is read-only. The `SET TRANSACTION` statement can also change the value of this variable. See SET TRANSACTION and START TRANSACTION.
- Command line: None
- Scope: Global, Session
- Dynamic: Yes
- Type: boolean
- Default Value: `OFF`
- Introduced: MariaDB 11.1

`tx_isolation`

- Description: The transaction isolation level. Setting this session variable via `set @@tx_isolation=` will take effect for only the subsequent transaction in the current session, much like SET TRANSACTION ISOLATION LEVEL. To set for a session, use `SET SESSION tx_isolation` or `SET @@session.tx_isolation`. See MDEV-31751. See also SET TRANSACTION ISOLATION LEVEL. In MariaDB 11.1, this system variable is deprecated and replaced by transaction_isolation.
- Command line: `--transaction-isolation=name`
- Scope: Global, Session
- Dynamic: Yes
- Type: enumeration
- Default Value: `REPEATABLE-READ`
- Valid Values: `READ-UNCOMMITTED`, `READ-COMMITTED`, `REPEATABLE-READ`, `SERIALIZABLE`
- Deprecated: MariaDB 11.1

`tx_read_only`

- Description: Default transaction access mode. If set to `OFF`, the default, access is read/write. If set to `ON`, access is read-only. The `SET TRANSACTION` statement can also change the value of this variable. See SET TRANSACTION and START TRANSACTION. In MariaDB 11.1, this system variable is deprecated and replaced by transaction_read_only.
- Command line: `--transaction-read-only=#`
- Scope: Global, Session
- Dynamic: Yes
- Type: boolean
- Default Value: `OFF`
- Deprecated: MariaDB 11.1

`unique_checks`

- Description: If set to 0, storage engines can (but are not required to) assume that duplicate keys are not present in input data. If set to 0, inserting duplicates into a `UNIQUE` index can succeed, causing the table to become corrupted. Set to 0 to speed up imports of large tables to InnoDB.

- Scope: Global, Session
- Dynamic: Yes
- Type: boolean
- Default Value: `1`

`updatable_views_with_limit`

- Description: Determines whether view updates can be made with an UPDATE or DELETE statement with a LIMIT clause if the view does not contain all primary or not null unique key columns from the underlying table. `0` prohibits this, while `1` permits it while issuing a warning (the default).
- Command line: `--updatable-views-with-limit=#`
- Scope: Global, Session
- Dynamic: Yes
- Type: boolean
- Default Value: `1`

`use_stat_tables`

- Description: Controls the use of engine-independent table statistics.
  - `never`: The optimizer will not use data from statistics tables.
  - `complementary`: The optimizer uses data from statistics tables if the same kind of data is not provided by the storage engine.
  - `preferably`: Prefer the data from statistics tables, if it's not available there, use the data from the storage engine.
  - `complementary_for_queries`: Same as `complementary`, but for queries only (to avoid needlessly collecting for ANALYZE TABLE).
  - `preferably_for_queries`: Same as `preferably`, but for queries only (to avoid needlessly collecting for ANALYZE TABLE).
- Command line: `--use-stat-tables=mode`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `enum`
- Default Value: `preferably_for_queries`

`validate_config`

- Description: Validates the server configuration (from configuration files and command line). Exits with exit code `0` on success, or non-zero on failure, without actually starting the server. Example:

  ```
  mariadbd --defaults-file=/etc/my.cnf --validate-config
  ```

  > `-help` or `-version` take precedence. If used with this option, the configuration check is **not** performed.

- Exit codes:
  - `0`: valid configuration
  - `2`: unknown option
  - `7`: unknown variable
- Command line: `--validate-config`

- Scope: Global
- Dynamic: No
- Data Type: numeric
- Introduced: MariaDB 13.0

`version`

- Description: Server version number. It may also include a suffix with configuration or build information. `-debug` indicates debugging support was enabled on the server, and `-log` indicates at least one of the binary log, general log or slow query log are enabled, for example `10.0.1-MariaDB-mariadb1precise-log`. Can be set at startup in order to fake the server version.
- Command line: `-V`, `--version[=name]`
- Scope: Global
- Dynamic: No
- Data Type: string

`version_comment`

- Description: Value of the COMPILATION_COMMENT option specified by CMake when building MariaDB, for example `mariadb.org binary distribution`.
- Scope: Global
- Dynamic: No
- Type: string

`version_compile_machine`

- Description: The machine type or architecture MariaDB was built on, for example `i686`.
- Scope: Global
- Dynamic: No
- Type: string

`version_compile_os`

- Description: Operating system that MariaDB was built on, for example `debian-linux-gnu`.
- Scope: Global
- Dynamic: No
- Type: string

`version_malloc_library`

- Description: Version of the used malloc library.
- Command line: None
- Scope: Global
- Dynamic: No
- Type: string

`version_source_revision`

- Description: Source control revision id for MariaDB source code, enabling one to see exactly which version of the source was used for a build.
- Command line: None

- Scope: Global
- Dynamic: No
- Type: string

`wait_timeout`

- Description: Time in seconds that the server waits for a connection to become active before closing it. The session value is initialized when a thread starts up from either the global value, if the connection is non-interactive, or from the interactive_timeout value, if the connection is interactive.
- Command line: `--wait-timeout=#`
- Scope: Global, Session
- Dynamic: Yes
- Type: numeric
- Default Value: `28800`
- Range: (Windows): `1` to `2147483`
- Range: (Other): `1` to `31536000`

`warning_count`

- Description: Read-only variable indicating the number of warnings, errors and notes resulting from the most recent statement that generated messages. See SHOW WARNINGS for more. Note warnings will only be recorded if sql_notes is true (the default).
- Scope: Session
- Dynamic: No
- Type: numeric

NEW_MODE

The `NEW_MODE` system variable and command line switch were introduced in MariaDB 11.4 to provide a way to enable new behavior in otherwise stable versions. Specifying a flag in the `NEW_MODE` variable enables the corresponding new behavior; otherwise, the old (stable) behavior is used. This can be useful to preserve execution plans in stable versions that may change when the new behavior is active.

A sample usage scenario is:

- a fix (new behavior) is pushed into stable releases (for example, MariaDB 11.4 and MariaDB 11.8). It becomes available in `NEW_MODE` but isn't enabled by default.
- in MariaDB 12.1, the fix (new behavior) is enabled without the switch. There's no way to turn it off.
  - `NEW_MODE` does not list the fix as something that can be turned on.
  - if you specify `fix_X` that is no longer switchable, a warning is printed. However, if you specify `fix_that_never_existed`, an error is produced.

Syntax

You can set `NEW_MODE` from the command line using the `--new-mode` option, or by setting the new_mode system variable.

```
SET [GLOBAL|SESSION] new_mode = 'fix_1[,fix_2]...';
```

The session value only affects the current client and can be changed by the client when required. Setting the global value requires the SUPER privilege, and the change will affect any clients that connect from that point forward.

Example

```
SET GLOBAL new_mode = 'FIX_DISK_TMPTABLE_COSTS';
...
SET new_mode = 'FIX_DISK_TMPTABLE_COSTS,FIX_INDEX_STATS_FOR_ALL_NULLS';
...
SET SESSION new_mode = 'FIX_INDEX_STATS_FOR_ALL_NULLS';

SET new_mode = '';
```

Available NEW_MODE Flags

1. `FIX_DISK_TMPTABLE_COSTS`
2. `FIX_INDEX_STATS_FOR_ALL_NULLS`

FIX_DISK_TMPTABLE_COSTS

From MariaDB 11.8.4 to MariaDB 12.0. Starting from MariaDB 12.1.2, this behavior is enabled by default.

This flag improves the cost computation for using temporary tables in certain cases, including semi-join subquery materialization (MDEV-37723).

FIX_INDEX_STATS_FOR_ALL_NULLS

From MariaDB 11.4.9 to MariaDB 12.0.

This flag improves the selection of execution plans when indexed columns contain only NULL values (MDEV-36761). Starting from MariaDB 12.1.2, this behavior is enabled by default.

For proper application of the fix, engine-independent statistics must be collected for tables having columns with only NULL values:

```
ANALYZE TABLE table_name PERSISTENT FOR ALL;
```

or at least for indexed columns with only NULL values:

```
ANALYZE TABLE table_name PERSISTENT FOR COLUMNS (b) INDEXES (key_b);
```

This page is licensed: CC BY-SA / Gnu FDL

OLD_MODE

The old_mode system variable was introduced to replace the old variable with a new one with better granularity.

MariaDB supports several different modes which allow you to tune it to suit your needs.

The most important ways for doing this are with SQL_MODE and `OLD_MODE`.

SQL_MODE is used for getting MariaDB to emulate behavior from other SQL servers, while `OLD_MODE` is used for emulating behavior from older MariaDB or MySQL versions.

`OLD_MODE` is a string with different options separated by commas (‘`,`’) without spaces. The options are case insensitive.

Normally `OLD_MODE` should be empty. It’s mainly used to get old behavior when switching to MariaDB or to a new major version of MariaDB, until you have time to fix your application.

Between major versions of MariaDB various options supported by `OLD_MODE` may be removed. This is intentional as we assume that the application will be fixed to conform with the new MariaDB behavior between releases.

In other words, `OLD_MODE` options are by design deprecated from the day they were added and will eventually be removed as any other deprecated feature.

You can check the variable's local and global value with:

```
SELECT @@OLD_MODE, @@GLOBAL.OLD_MODE;
```

You can set the `OLD_MODE` either from the command line (option `--old-mode`) or by setting the old_mode system variable.

Non-default old mode features are deprecated by design, and a warning is issued when set.

Modes

The different values of `OLD_MODE` are:

2_DIGIT_YEAR

From MariaDB 13.0, restores support for the two-digit `YEAR(2)` data type, which is otherwise no longer accepted. Like other `OLD_MODE` flags, it is deprecated by design and intended only as a temporary migration aid.

COMPAT_5_1_CHECKSUM

From MariaDB 10.9, the –old option is deprecated. This option allows behaviour of the –old option for enabling the old-style checksum for `CHECKSUM TABLE` that MySQL 5.1 supports

IGNORE_INDEX_ONLY_FOR_JOIN

From MariaDB 10.9, the –old option is deprecated. This option allows behaviour of the –old option for disabling the index only for joins, but allow it for ORDER BY.

LOCK_ALTER_TABLE_COPY

From MariaDB 11.2. The non-locking copy ALTER introduced in MDEV-16329 should be beneficial in the vast majority of cases, but scenarios can exist which significantly impact performance. For example, RBR on tables without a primary key. When non-locking ALTER is performed on such a table, and DML affecting a large number of records is run in parallel, the ALTER can become extremely slow, and further DML can also be affected. If there is a chance of such scenarios (and no possibility of improving the schema by immediately adding primary keys), ALTER should be performed with the explicit LOCK=SHARED clause. If this is also impossible, then LOCK_ALTER_TABLE_COPY flag should be added to the old_mode variable until the schema can be improved.

NO_DUP_KEY_WARNINGS_WITH_IGNORE

Don't print duplicate key warnings when using INSERT IGNORE.

NO_NULL_COLLATION_IDS

A compatibility setting to support connectors (in particular MySQL Connector/NET) that give an exception when collation ids returned by SHOW COLLATION are NULL. It is automatically set when a MySQL Connector/NET connection is determined. From MariaDB 10.11.7, MariaDB 11.0.5, MariaDB 11.1.4, MariaDB 11.2.3.

NO_PROGRESS_INFO

Don't show progress information in SHOW PROCESSLIST.

OLD_FLUSH_STATUS

From MariaDB 11.5, restores the pre-MariaDB 11.5 behavior of FLUSH STATUS.

SESSION_USER_IS_USER

From MariaDB 11.7, restores the pre-MariaDB 11.7 behavior of SESSION_USER.

UTF8_IS_UTF8MB3

From MariaDB 10.6.1, the main name of the previous 3-byte `utf8` character set was changed to `utf8mb3`. When this flag is set, `utf8` is an alias for `utf8mb3`; when it is not set, `utf8` is an alias for `utf8mb4`.

> **Warning:**
>
> From MariaDB 13.1, `UTF8_IS_UTF8MB3` is no longer set by default. The default `old_mode` is now empty, so `utf8` is an alias for `utf8mb4` by default. The flag is also deprecated from MariaDB 13.1, and setting it raises a deprecation warning.

ZERO_DATE_TIME_CAST

When a TIME value is cast to a DATETIME, the date part will be `0000-00-00`, not CURRENT_DATE (as dictated by the SQL standard).

OLD_MODE and Stored Programs

In contrast to SQL_MODE, stored programs use the current user's `OLD_MODE` value.

Changes to `OLD_MODE` are not sent to replicas.

Examples

This example shows how to get a readable list of enabled OLD_MODE flags:

```
SELECT REPLACE(@@OLD_MODE, ',', '\n');
+--------------------------------------------------+
| REPLACE(@@OLD_MODE, ',', '\n')                   |
+--------------------------------------------------+
| NO_DUP_KEY_WARNINGS_WITH_IGNORE                  |
| NO_PROGRESS_INFO                                 |
+--------------------------------------------------+
```

Adding a new flag:

```
SET @@OLD_MODE = CONCAT(@@OLD_MODE, ',NO_PROGRESS_INFO');
```

If the specified flag is already ON, the above example has no effect but does not produce an error.

How to unset a flag:

```
SET @@OLD_MODE = REPLACE(@@OLD_MODE, 'NO_PROGRESS_INFO', '');
```

How to check if a flag is set:

```
SELECT @@OLD_MODE LIKE '%NO_PROGRESS_INFO';
+-----------------------------------+
| @@OLD_MODE LIKE '%NO_PROGESS_INFO' |
+-----------------------------------+
|                                 1 |
+-----------------------------------+
```

From MariaDB 11.3:

```
SET @@OLD_MODE = CONCAT(@@OLD_MODE, ',NO_PROGRESS_INFO');
Query OK, 0 rows affected, 1 warning (0.000 sec)

SHOW WARNINGS;
+---------+------+-----------------------------------------------------------------------------+
| Level   | Code | Message                                                                     |
+---------+------+-----------------------------------------------------------------------------+
| Warning | 1287 | 'NO_PROGRESS_INFO' is deprecated and will be removed in a future release |
+---------+------+-----------------------------------------------------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

SQL_MODE

MariaDB supports several different modes which allow you to tune it to suit your needs.

The most important ways for doing this are using `SQL_MODE` (controlled by the sql_mode system variable) and OLD_MODE (the old_mode system variable). `SQL_MODE` is used for getting MariaDB to emulate behavior from other SQL servers, while OLD_MODE is used for emulating behavior from older MariaDB or MySQL versions.

`SQL_MODE` is a string with different options separated by commas (‘`,`’) without spaces. The options are case insensitive.

You can check the local and global value of it with:

```
SELECT @@SQL_MODE, @@GLOBAL.SQL_MODE;
```

Setting SQL_MODE

Defaults

From version	Default sql_mode setting
MariaDB 10.2.4	STRICT_TRANS_TABLES, ERROR_FOR_DIVISION_BY_ZERO , NO_AUTO_CREATE_USER, NO_ENGINE_SUBSTITUTION
MariaDB 10.1.7	NO_ENGINE_SUBSTITUTION, NO_AUTO_CREATE_USER
<= MariaDB 10.1.6	No value

You can set the `SQL_MODE` either from the command line (the `--sql-mode` option) or by setting the sql_mode system variable.

```
SET sql_mode = 'modes';
SET GLOBAL sql_mode = 'modes';
```

The session value only affects the current client, and can be changed by the client when required. To set the global value, the SUPER privilege is required, and the change affects any clients that connect from that point on.

SQL_MODE Values

The different `SQL_MODE` values are:

ALLOW_INVALID_DATES

Allow any day between 1-31 in the day part. This is convenient when you want to read in all (including wrong data) into the database and then manipulate it there.

Note, that MariaDB assumes that table content matches the current setting of this mode. If you enable it, insert some invalid dates into the table and then disable it for a session, the result will be not well defined — some queries

might return invalid dates, while other will not.

ANSI

Changes the SQL syntax to be closer to ANSI SQL.

Sets: REAL_AS_FLOAT, PIPES_AS_CONCAT, ANSI_QUOTES, IGNORE_SPACE.

It also adds a restriction: an error will be returned if a subquery uses an aggregating function with a reference to a column from an outer query in a way that cannot be resolved.

If set, SHOW CREATE TABLE output will not display MariaDB-specific table attributes.

ANSI_QUOTES

Changes the double-quote character (`"`) to be treated as a backtick (`` ` ``), the identifier quote character. This can break old MariaDB applications which assume that `"` is used as a string quote character.

DB2

Same as: PIPES_AS_CONCAT, ANSI_QUOTES , IGNORE_SPACE, DB2, NO_KEY_OPTIONS, NO_TABLE_OPTIONS, NO_FIELD_OPTIONS

If set, SHOW CREATE TABLE output will not display MariaDB-specific table attributes.

EMPTY_STRING_IS_NULL

Oracle-compatibility option that translates Item_string created in the parser to `Item_null`, and translates binding an empty string as prepared statement parameters to binding `NULL`. For example, `SELECT '' IS NULL` returns TRUE, `INSERT INTO t1 VALUES ('')` inserts `NULL`.

ERROR_FOR_DIVISION_BY_ZERO

If not set, division by zero returns NULL. If set returns an error if one tries to update a column with 1/0 and returns a warning as well. Also see MDEV-8319. Default since MariaDB 10.2.4.

HIGH_NOT_PRECEDENCE

Compatibility option for MySQL 5.0.1 and before; This changes `NOT a BETWEEN b AND c` to be parsed as `(NOT a) BETWEEN b AND c`

IGNORE_BAD_TABLE_OPTIONS

If this is set generate a warning (not an error) for wrong table option in CREATE TABLE. Also, since 10.0.13, do not comment out these wrong table options in SHOW CREATE TABLE.

IGNORE_SPACE

Allow one to have spaces (including tab characters and new line characters) between function name and '('. The drawback is that this causes built in functions to become reserved words.

MAXDB

Same as: PIPES_AS_CONCAT, ANSI_QUOTES, IGNORE_SPACE, MAXDB, NO_KEY_OPTIONS, NO_TABLE_OPTIONS, NO_FIELD_OPTIONS, NO_AUTO_CREATE_USER.

Also has the effect of silently converting TIMESTAMP fields into DATETIME fields when created or modified.

If set, SHOW CREATE TABLE output will not display MariaDB-specific table attributes.

MSSQL

Additionally implies the following: PIPES_AS_CONCAT, ANSI_QUOTES, IGNORE_SPACE, NO_KEY_OPTIONS, NO_TABLE_OPTIONS, NO_FIELD_OPTIONS.

Additionally from MariaDB 10.4.5, implements a limited subset of Microsoft SQL Server's language. See SQL_MODE=MSSQL for more.

If set, SHOW CREATE TABLE output will not display MariaDB-specific table attributes.

MYSQL323

Same as: NO_FIELD_OPTIONS, HIGH_NOT_PRECEDENCE.

MYSQL40

Same as: NO_FIELD_OPTIONS, HIGH_NOT_PRECEDENCE.

NO_AUTO_CREATE_USER

Don't automatically create users with `GRANT` unless authentication information is specified. If none is provided, will produce a 1133 error: "Can't find any matching row in the user table". Default since MariaDB 10.1.7.

NO_AUTO_VALUE_ON_ZERO

If set, don't generate an AUTO_INCREMENT on INSERT of zero in an `AUTO_INCREMENT` column, or when adding an AUTO_INCREMENT attribute with the ALTER TABLE statement. Normally both `zero` and `NULL` generate new `AUTO_INCREMENT` values.

NO_BACKSLASH_ESCAPES

Disables using the backslash character `\` as an escape character within strings, making it equivalent to an ordinary character.

NO_DIR_IN_CREATE

Ignore all INDEX DIRECTORY and DATA DIRECTORY directives when creating a table. Can be useful on replica servers.

NO_ENGINE_SUBSTITUTION

If not set, if the available storage engine specified by a CREATE TABLE or ALTER TABLE is not available, a warning is given and the default storage engine is used instead. If set, generate a 1286 error when creating a table if the specified storage engine is not available. See also enforce_storage_engine. Default since MariaDB 10.1.7.

NO_FIELD_OPTIONS

Remove MariaDB-specific column options from the output of SHOW CREATE TABLE. This is also used by the portability mode of mariadb-dump.

NO_KEY_OPTIONS

Remove MariaDB-specific index options from the output of SHOW CREATE TABLE. This is also used by the portability mode of mariadb-dump.

NO_TABLE_OPTIONS

Remove MariaDB-specific table options from the output of SHOW CREATE TABLE. This is also used by the portability mode of mariadb-dump.

NO_UNSIGNED_SUBTRACTION

When enabled, subtraction results are signed even if the operands are unsigned.

NO_ZERO_DATE

Don't allow '0000-00-00' as a valid date in strict mode (produce a 1525 error). Zero dates can be inserted with IGNORE. If not in strict mode, a warning is generated.

NO_ZERO_IN_DATE

Don't allow dates where the year is not zero but the month or day parts of the date *are* zero (produce a 1525 error). For example, with this set, '0000-00-00' is allowed, but '1970-00-10' or '1929-01-00' are not. If the ignore option is used, MariaDB will insert '0000-00-00' for those types of dates. If not in strict mode, a warning is generated instead.

ONLY_FULL_GROUP_BY

For SELECT … GROUP BY queries, disallow SELECTing columns which are not referred to in the GROUP BY clause, unless they are passed to an aggregate function like COUNT() or MAX(). Produce a 1055 error.

ORACLE

In all versions of MariaDB up to MariaDB 10.2, this sets `sql_mode` that is equivalent to: PIPES_AS_CONCAT, ANSI_QUOTES, IGNORE_SPACE, NO_KEY_OPTIONS, NO_TABLE_OPTIONS, NO_FIELD_OPTIONS, NO_AUTO_CREATE_USER

From MariaDB 10.3, this mode also sets SIMULTANEOUS_ASSIGNMENT and configures the server to understand a large subset of Oracle's PL/SQL language instead of MariaDB's traditional syntax for stored routines. See SQL_MODE=ORACLE From MariaDB 10.3.

If set, SHOW CREATE TABLE output will not display MariaDB-specific table attributes.

PAD_CHAR_TO_FULL_LENGTH

Trailing spaces in CHAR columns are by default trimmed upon retrieval. With PAD_CHAR_TO_FULL_LENGTH enabled, no trimming occurs. Does not apply to VARCHARs.

PIPES_AS_CONCAT

Allows using the pipe character (ASCII 124) as string concatenation operator. This means that `"A" || "B"` can be used in place of `CONCAT("A", "B")`.

POSTGRESQL

Same as: PIPES_AS_CONCAT, ANSI_QUOTES, IGNORE_SPACE, POSTGRESQL, NO_KEY_OPTIONS, NO_TABLE_OPTIONS, NO_FIELD_OPTIONS.

If set, SHOW CREATE TABLE output will not display MariaDB-specific table attributes.

REAL_AS_FLOAT

`REAL` is a synonym for FLOAT rather than DOUBLE.

SIMULTANEOUS_ASSIGNMENT

Setting this makes the SET part of the UPDATE statement evaluate all assignments simultaneously, not left-to-right. From MariaDB 10.3.5.

STRICT_ALL_TABLES

Strict mode. Statements with invalid or missing data are aborted and rolled back. For a non-transactional storage engine with a statement affecting multiple rows, this may mean a partial insert or update if the error is found in a row beyond the first.

STRICT_TRANS_TABLES

Strict mode. Statements with invalid or missing data are aborted and rolled back, except that for non-transactional storage engines and statements affecting multiple rows where the invalid or missing data is not the first row, MariaDB will convert the invalid value to the closest valid value, or, if a value is missing, insert the column default value. Default since MariaDB 10.2.4.

TIME_ROUND_FRACTIONAL

With this mode unset, MariaDB truncates fractional seconds when changing precision to smaller. When set, MariaDB will round when converting to TIME, DATETIME and TIMESTAMP, and truncate when converting to DATE. Since MariaDB 10.4.1

TRADITIONAL

Makes MariaDB work like a traditional SQL server. Same as: STRICT_TRANS_TABLES, STRICT_ALL_TABLES, NO_ZERO_IN_DATE, NO_ZERO_DATE, ERROR_FOR_DIVISION_BY_ZERO, NO_ENGINE_SUBSTITUTION, NO_AUTO_CREATE_USER.

Strict Mode

A mode where at least one of `STRICT_TRANS_TABLES` or `STRICT_ALL_TABLES` is enabled is called *strict mode*.

With strict mode set (default from MariaDB 10.2.4), statements that modify tables (either transactional for `STRICT_TRANS_TABLES` or all for `STRICT_ALL_TABLES`) will fail, and an error will be returned instead. The IGNORE keyword can be used when strict mode is set to convert the error to a warning.

With strict mode not set (default in version <= MariaDB 10.2.3), MariaDB will automatically adjust invalid values, for example, truncating strings that are too long, or adjusting numeric values that are out of range, and produce a warning.

Statements that don't modify data will return a warning when adjusted regardless of mode.

SQL_MODE and Stored Programs

Stored programs and views always use the SQL_MODE that was active when they were created. This means that users can safely change session or global SQL_MODE; the stored programs they use will still work as usual.

It is possible to change session SQL_MODE within a stored program. In this case, the new SQL_MODE will be in effect only in the body of the current stored program. If it calls some stored procedures, they will not be affected by the change.

Some Information Schema tables (such as ROUTINES) and SHOW CREATE statements such as SHOW CREATE PROCEDURE show the SQL_MODE used by the stored programs.

Examples

This example shows how to get a readable list of enabled SQL_MODE flags:

```
SELECT REPLACE(@@SQL_MODE, ',', '\n');
+--------------------------------------------------------------------------+
| REPLACE(@@SQL_MODE, ',', '\n')                                           |
+--------------------------------------------------------------------------+
| STRICT_TRANS_TABLES
NO_ZERO_IN_DATE
NO_ZERO_DATE
NO_ENGINE_SUBSTITUTION |
+--------------------------------------------------------------------------+
```

Adding a new flag:

```
SET @@SQL_MODE = CONCAT(@@SQL_MODE, ',NO_ENGINE_SUBSTITUTION');
```

If the specified flag is already ON, the above example has no effect but does not produce an error.

How to unset a flag:

```
SET @@SQL_MODE = REPLACE(@@SQL_MODE, 'NO_ENGINE_SUBSTITUTION', '');
```

How to check if a flag is set:

```
SELECT @@SQL_MODE LIKE '%NO_ZERO_DATE%';
+-----------------------------------+
| @@SQL_MODE LIKE '%NO_ZERO_DATE%' |
+-----------------------------------+
|                                 1 |
+-----------------------------------+
```

Without and with strict mode:

```
CREATE TABLE strict (s CHAR(5), n TINYINT);

INSERT INTO strict VALUES ('MariaDB', '128');
Query OK, 1 row affected, 2 warnings (0.14 sec)

SHOW WARNINGS;
+---------+------+--------------------------------------------+
| Level   | Code | Message                                    |
+---------+------+--------------------------------------------+
| Warning | 1265 | Data truncated for column 's' at row 1     |
| Warning | 1264 | Out of range value for column 'n' at row 1 |
+---------+------+--------------------------------------------+
2 rows in set (0.00 sec)

SELECT * FROM strict;
+-------+------+
| s     | n    |
+-------+------+
| Maria |  127 |
+-------+------+

SET sql_mode='STRICT_TRANS_TABLES';

INSERT INTO strict VALUES ('MariaDB', '128');
ERROR 1406 (22001): Data too long for column 's' at row 1
```

Overriding strict mode with the IGNORE keyword:

```
INSERT IGNORE INTO strict VALUES ('MariaDB', '128');
Query OK, 1 row affected, 2 warnings (0.15 sec)

Securing MariaDB

See Running MariaDB as root.

Understand the implications of running MariaDB Server as root. This section highlights security risks and provides guidance on configuring MariaDB Server to operate with less privileged user accounts.

See MariaDB on SELinux.

Secure MariaDB Server with SELinux. This section guides you through configuring SELinux policies to enhance the security posture of your MariaDB deployments on Linux systems.

See Securing MariaDB Logs.

Learn how to harden MariaDB log files by implementing at-rest encryption, TLS for transit, strict OS permissions, and automated rotation to ensure data integrity and regulatory compliance.

See Security Vulnerabilities (CVE) Fixed in MariaDB.

This is the master list of CVEs fixed across all versions of MariaDB.

See Security Vulnerabilities (CVE) Fixed in Oracle MySQL That Did Not Exist in MariaDB.

This page lists all CVEs that were fixed in MySQL and mentioned in Oracle CPU Advisories, but that — to the best of our knowledge — were never present in MariaDB.

This page is licensed: CC BY-SA / Gnu FDL

Running MariaDB as root

MariaDB should never be run as the system root user (this is unrelated to the MariaDB root user). If it is, any user with the `FILE` privilege can create or modify any files on the server as root.

If you attempt to run the server (`mariadbd`) as root, MariaDB normally returns the error **Fatal error: Please read "Security" section of the manual to find out how to run mariadbd as root!**. If you need to override this restriction, start `mariadbd` with the user=root option.

Better practice, and the default in most situations, is to use a separate user, exclusively used for MariaDB. In most distributions, this user is called `mysql`.

This page is licensed: CC BY-SA / Gnu FDL

MariaDB on SELinux

Security-Enhanced Linux (SELinux) is a Linux kernel module that provides a framework for configuring mandatory access control (MAC) system for many resources on the system. It is enabled by default on some Linux distributions, including RHEL, CentOS, Fedora, and other similar Linux distribution. SELinux prevents programs from accessing files, directories or ports unless it is configured to access those resources.

Verifying Whether SELinux Is Enabled

To verify whether SELinux is enabled, execute the getenforce command. For example:

```
getenforce
```

Temporarily Putting mysqld Into Permissive Mode

When you are troubleshooting issues that you think SELinux might be causing, it can help to temporarily put `mysqld_t` into permissive mode. This can be done by executing the semanage command. For example:

```
sudo semanage permissive -a mysqld_t
```

If that solved the problem, it means that the current SELinux policy is the culprit. You need to adjust the SELinux policy or labels for MariaDB.

Configuring a MariaDB Server SELinux Policy

MariaDB Server should work with your default distribution policy (which is usually part of the `selinux-policy` or `selinux-policy-targeted` system package). If you use `mysqld_safe`, you will need an additional policy file, `mariadb.pp`, which is installed together with the MariaDB Server. It will be loaded automatically if you have `/usr/sbin/semodule` installed, but you can load it manually anytime with

```
/usr/sbin/semodule -i /usr/share/mariadb/policy/selinux/mariadb.pp
```

Note that this policy file extends, rather than replaces the system policy.

Setting File Contexts

SELinux uses file contexts as a way to determine who should be able to access that file.

File contexts are managed with the semanage fcontext and restorecon commands.

On many systems, the semanage utility is installed by the `policycoreutils-python` package, and the restorecon utility is installed by the `policycoreutils` package. You can install these with the following command:

```
sudo yum install policycoreutils policycoreutils-python
```

A file or directory's current context can be checked by executing `ls` with the `--context` or `--scontext` options.

Setting the File Context for the Data Directory

If you use a custom directory for datadir, then you may need to set the file context for that directory. The SELinux file context for MariaDB data files is `mysqld_db_t`. You can determine if this file context is present on your system and which files or directories it is associated with by executing the following command:

```
sudo semanage fcontext --list | grep mysqld_db_t
```

If you would like to set the file context for your custom directory for your datadir, then that can be done by executing the semanage fcontext and restorecon commands. For example:

```
sudo semanage fcontext -a -t mysqld_db_t "/mariadb/data(/.*)?"
sudo restorecon -Rv /mariadb/data
```

If you would like to check the current file context, you can do so by executing `ls` with the `--context` or `--scontext` options. For example:

```
ls --directory --scontext /mariadb/data
```

Setting the File Context for Log Files

If you use a custom directory for log files, then you may need to set the file context for that directory. The SELinux file context for MariaDB log files is `mysqld_log_t`. You can determine if this file context is present on your system and which files or directories it is associated with by executing the following command:

```
sudo semanage fcontext --list | grep mysqld_log_t
```

If you would like to set the file context for your custom directory for log files, then that can be done by executing the semanage fcontext and restorecon commands. For example:

```
sudo semanage fcontext -a -t mysqld_log_t "/var/log/mysql(/.*)?"
sudo restorecon -Rv /var/log/mysql
```

If you would like to check the current file context, you can do so by executing `ls` with the `--context` or `--scontext` options. For example:

```
ls --directory --scontext /var/log/mysql
```

Setting the File Context for Option Files

If you use a custom directory for option files, then you may need to set the file context for that directory. The SELinux file context for MariaDB option files is `mysqld_etc_t`. You can determine if this file context is present on your system and which files or directories it is associated with by executing the following command:

```
sudo semanage fcontext --list | grep mysqld_etc_t
```

If you would like to set the file context for your custom directory for option files, then that can be done by executing the semanage fcontext and restorecon commands. For example:

```
sudo semanage fcontext -a -t mysqld_etc_t "/etc/mariadb(/.*)?"
sudo restorecon -Rv /etc/mariadb
```

If you would like to check the current file context, you can do so by executing `ls` with the `--context` or `--scontext` options. For example:

```
ls --directory --scontext /etc/mariadb
```

Setting the Unix Socket

A custom location for the socket means it needs to have the right file context of `mysqld_var_run_t` for permitted application to connect to the socket.

```
sudo semanage fcontext -a -t mysqld_var_run_t "/mariadb/run/mariadb.sock"
```

A newly created socket with get the right context.

Allowing Access to the Tmpfs File Context

If you wanted to mount your tmpdir on a `tmpfs` file system or wanted to use a `tmpfs` file system on `/run/shm`, then you might need to allow `mysqld_t` to have access to a couple tmpfs-related file contexts. For example:

```
cd /usr/share/mysql/policy/selinux/
tee ./mysqld_tmpfs.te <<EOF
module mysqld_tmpfs 1.0;

require {
type tmpfs_t;
type mysqld_t;
class dir { write search read remove_name open getattr add_name };
class file { write getattr read lock create unlink open };
}

allow mysqld_t tmpfs_t:dir { write search read remove_name open getattr add_name };

allow mysqld_t tmpfs_t:file { write getattr read lock create unlink open }
EOF
sudo checkmodule -M -m mysqld_tmpfs.te -o mysqld_tmpfs.mod
sudo semodule_package -m mysqld_tmpfs.mod -o mysqld_tmpfs.pp
sudo semodule -i mysqld_tmpfs.pp
```

Troubleshooting SELinux Issues

You might need to troubleshoot SELinux-related issues in cases, such as:

- MariaDB is using a non-default port.
- MariaDB is reading from or writing to some files (datadir, log files, option files, etc.) located at non-default paths.
- MariaDB is using a plugin that requires access to resources that default installations do not use.

File System Permission Errors

If the file system permissions for some MariaDB directory look fine, but the MariaDB error log still has errors that look similar to the following:

```
130321 11:50:51 mysqld_safe Starting mysqld daemon with databases from /datadir
...
2013-03-21 11:50:52 2119 [Warning] Can't create test file /datadir/
2013-03-21 11:50:52 2119 [Warning] Can't create test file /datadir/
...
2013-03-21 11:50:52 2119 [ERROR] /usr/sbin/mysqld: Can't create/write to file
    '/datadir/boxy.pid' (Errcode: 13 - Permission denied)
2013-03-21 11:50:52 2119 [ERROR] Can't start server: can't create PID file:
    Permission denied
130321 11:50:52 mysqld_safe mysqld from pid file /datadir/boxy.pid ended
```

Then check SELinux's `/var/log/audit/audit.log` for log entries that look similar to the following:

```
type=AVC msg=audit(1363866652.030:24): avc:  denied  { write } for  pid=2119
    comm="mysqld" name="datadir" dev=dm-0 ino=394
    scontext=unconfined_u:system_r:mysqld_t:s0
    tcontext=unconfined_u:object_r:default_t:s0 tclass=dir
```

If you see any entries that look similar to this, then you most likely need to adjust the file contexts for some files or directories. See Setting File Contexts for more information on how to do that.

SELinux and MariaDB On a Different Port

TCP and UDP ports are enabled for permission to bind too. If you are using a different port, or some Galera ports, configure SELinux to be able to use those ports:

```
sudo semanage port -a -t mysqld_port_t -p tcp 3307
```

Generating SELinux Policies with audit2allow

In some cases, a MariaDB system might need non-standard policies. It is possible to create these policies from the SELinux audit log using the audit2allow utility. The semanage and semodule utilities will also be needed.

On many systems, the audit2allow and semanage utilities are installed by the `policycoreutils-python` package, and the semodule utility is installed by the `policycoreutils` package. You can install these with the following command:

```
sudo yum install policycoreutils policycoreutils-python
```

The following process can be used to generate a policy from the audit log:

- Remove dontaudits from the policy:

```
sudo semodule -DB
```

- Temporarily put `mysqld_t` into permissive mode. For example:

```
sudo semanage permissive -a mysqld_t
```

- Start MariaDB.
- Do whatever was causing SELinux errors.
- Use the generated audit log to create a policy:

```
sudo grep mysqld /var/log/audit/audit.log | audit2allow -M mariadb_local
sudo semodule -i mariadb_local.pp
```

- Pull `mysqld_t` out of permissive mode. For example:

```
sudo semanage permissive -d mysqld_t
```

- Restore dontaudits for the policy:

```
sudo setmodule -B
```

The same procedure can be used if MariaDB starts but SELinux prevents it from functioning correctly. For example, SELinux may prevent PAM plugin from authenticating users. The solution is the same — enable auditing, switch to permissive, do, whatever SELinux didn't allow you to, create a policy from the audit log.

When you discover any needed SELinux permissions, please report the needed permissions to your operating system bug tracking so all users can benefit from your work (e.g. Red Hat Bugzilla).

This page is licensed: CC BY-SA / Gnu FDL

Encryption

MariaDB's security architecture distinguishes between data moving across the network (Data-in-Transit) and data stored on disk (Data-at-Rest).

See TLS and Cryptography Libraries.

MariaDB links to cryptography libraries (OpenSSL, wolfSSL, GnuTLS, Schannel) either statically or dynamically. How to verify the active library and version.

See Data-in-Transit Encryption.

Data-in-Transit Encryption

- Protects credentials and query results from "man-in-the-middle" attacks during client-server communication.
- Uses the TLS protocol. It handles the handshake, identity verification, and encryption of the network stream.
- Utilizes Asymmetric Key Pairs (Public/Private keys) and Certificates (PEM/CRT files) managed by libraries like OpenSSL.
- Defined in the `[mariadb]` section using `ssl_cert`, `ssl_key`, and `ssl_ca`.

See Data-at-Rest Encryption.

Data-at-Rest Encryption

- Protects physical data files (InnoDB/Aria tables, Redo logs, and Binary logs) if the storage media or backups are stolen.
- Uses Symmetric Encryption (typically AES) managed by specialized Key Management Plugins.
- Uses Symmetric Keys identified by a `Key ID`. These are fetched from a local file, AWS KMS, or HashiCorp Vault.
- Enabled via variables like `innodb_encrypt_tables` and requires a specific plugin (e.g., `file_key_management`) to be loaded.

This page is licensed: CC BY-SA / Gnu FDL

TLS and Cryptography Libraries

> These libraries provide the cryptographic foundations for both network (or data-in-transit) encryption (TLS) and data-at-rest encryption (TDE).

When MariaDB Server is compiled with TLS[26] and cryptography support, it is usually either statically linked with MariaDB's bundled TLS and cryptography library or dynamically linked with the system's OpenSSL library. MariaDB's bundled TLS library is either wolfSSL or yaSSL, depending on the server version.

When a MariaDB client or client library is compiled with TLS and cryptography support, it is usually either statically linked with MariaDB's bundled TLS and cryptography library or dynamically linked with the system's TLS and cryptography library, which can be OpenSSL, GnuTLS, or Schannel.

Checking Dynamically vs. Statically Linked

Dynamically linking MariaDB to the system's TLS and cryptography library can often be beneficial, since this allows you to fix bugs in the system's TLS and cryptography library independently of MariaDB. For example, when information on the Heartbleed Bug in OpenSSL was released in 2014, the bug could be mitigated by simply updating your system to use a fixed version of the OpenSSL library, then restarting the MariaDB Server.

LINUX

You can verify that `mariadbd` is dynamically linked to the OpenSSL shared library on your system with this ldd command:

```
ldd $(which mariadbd) | grep -E '(libssl|libcrypto)'
        libssl.so.10 => /lib64/libssl.so.10 (0x00007f8736386000)
        libcrypto.so.10 => /lib64/libcrypto.so.10 (0x00007f8735f25000)
```

MACOS

You can verify that `mariadbd` is dynamically linked to the OpenSSL shared library on your system with this command:

```
otool -L $(which mariadbd) | grep -E '(libssl|libcrypto)'
    /opt/homebrew/opt/openssl@3/lib/libssl.3.dylib (compatibility version 3.0.0, current version 3.0.0)
    /opt/homebrew/opt/openssl@3/lib/libcrypto.3.dylib (compatibility version 3.0.0, current version
3.0.0)
```

If the command does not return any results, either your `mariadbd` is statically linked to the TLS and cryptography library on your system or your `mariadbd` is not built with TLS and cryptography support at all.

Checking If the Server Uses OpenSSL

If you aren't sure whether your server is linked with OpenSSL or the bundled TLS library, then you can check the value of the have_openssl system variable. For example:

```
SHOW GLOBAL VARIABLES LIKE 'have_openssl';
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| have_openssl  | YES   |
+---------------+-------+
```

Checking the Server's OpenSSL Version

If you want to see what version of OpenSSL your server is using, check the value of the version_ssl_library system variable:

```
SHOW GLOBAL VARIABLES LIKE 'version_ssl_library';
+--------------------+--------------------------------+
| Variable_name      | Value                          |
+--------------------+--------------------------------+
| version_ssl_library | OpenSSL 1.0.1e-fips 11 Feb 2013 |
+--------------------+--------------------------------+
```

Note that the version returned by this system variable does not necessarily correspond to the exact version of the OpenSSL package installed on the system. OpenSSL shared libraries tend to contain interfaces for multiple versions at once, to allow for backward compatibility. Therefore, if the OpenSSL package installed on the system is newer than the OpenSSL version that the MariaDB Server binary was built with, the MariaDB Server binary might use one of the interfaces for an older version. See MDEV-15848 for more information:

```
$ cat /etc/redhat-release
Red Hat Enterprise Linux Server release 7.5 (Maipo)
$ rpm -q openssl
openssl-1.0.2k-12.el7.x86_64
$ mariadb -u root --batch --execute="SHOW GLOBAL VARIABLES LIKE 'version_ssl_library';"
Variable_name   Value
version_ssl_library     OpenSSL 1.0.1e-fips 11 Feb 2013
$ ldd $(which mariadbd) | grep libcrypto
        libcrypto.so.10 => /lib64/libcrypto.so.10 (0x00007f3dd3482000)
$ readelf -a /lib64/libcrypto.so.10 | grep SSLeay_version
  1374: 000000000006f5d0    21 FUNC    GLOBAL DEFAULT   13 SSLeay_version@libcrypto.so.10
  1375: 000000000006f5f0    21 FUNC    GLOBAL DEFAULT   13 SSLeay_version@OPENSSL_1.0.1
  1377: 000000000006f580    70 FUNC    GLOBAL DEFAULT   13 SSLeay_version@@OPENSSL_1.0.2
```

FIPS Certification

Federal Information Processing Standards (FIPS) are standards published by the U.S. federal government that are used to establish requirements for various aspects of computer systems. FIPS 140-2 is a set of standards for security requirements for cryptographic modules.

This standard is relevant when discussing the TLS and cryptography libraries used by MariaDB. Some of these libraries have been certified to meet the standards set by FIPS 140-2.

FIPS Certification by OpenSSL

The OpenSSL library has a special FIPS mode that has been certified to meet the FIPS 140-2 standard. In FIPS mode, only algorithms and key sizes that meet the FIPS 140-2 standard are enabled by the library.

MariaDB does not yet support enabling FIPS mode within the database server. See MDEV-20260 for more information. Therefore, if you would like to use OpenSSL's FIPS mode with MariaDB, then you would either need to enable FIPS mode at the kernel level or enable it via the OpenSSL configuration file, system-wide or only for the MariaDB process.. See the following resources for more information on how to do that:

- Red Hat Enterprise Linux 7: Security Guide: Chapter 8. Federal Standards and Regulations
- Ubuntu Security Certifications Documentation: FIPS for Ubuntu 16.04 and 18.04
- OpenSSL 1.0.2, configuration file method
- OpenSSL 3.0 configuration file method

FIPS Certification by wolfSSL

The standard version of the wolfSSL library has not been certified to meet the FIPS 140-2 standard, but a special "FIPS-ready" version has been certified. Unfortunately, the "FIPS-ready" version of wolfSSL uses a license that is incompatible with MariaDB's license, so it cannot be used with MariaDB.

FIPS Certification by yaSSL

The yaSSL library has not been certified to meet the FIPS 140-2 standard.

Libraries Used by Each Platform and Package

MariaDB Server

MariaDB Server on Windows

MariaDB Server is statically linked with the bundled wolfSSL library in MSI and ZIP packages on Windows.

MariaDB Server on Linux

MariaDB Server in Binary Tarballs

MariaDB Server is statically linked with the bundled wolfSSL library in binary tarballs on Linux.

MariaDB Server in DEB Packages

MariaDB Server is dynamically linked with the system's OpenSSL library in .deb packages.

See Differences in MariaDB in Debian (and Ubuntu) for more information.

MariaDB Server in RPM Packages

MariaDB Server is dynamically linked with the system's OpenSSL library in .rpm packages.

MariaDB Clients and Utilities

MariaDB Connector/C has been included with MariaDB Server, and the bundled and the clients and utilities are linked with it. On some platforms, MariaDB Connector/C and these clients and utilities may use a different TLS library than the one used by MariaDB Server and libmysqlclient.

MariaDB Clients and Utilities on Windows

MariaDB's clients and utilities and MariaDB Connector/C are dynamically linked with the system's Schannel libraries in MSI and ZIP packages on Windows. libmysqlclient is still statically linked with the bundled wolfSSL library.

MariaDB Clients and Utilities on Linux

MariaDB Clients and Utilities in Binary Tarballs

MariaDB's clients and utilities and MariaDB Connector/C are statically linked with the GnuTLS library in binary tarballs on Linux. libmysqlclient is still statically linked with the bundled wolfSSL library.

MariaDB Clients and Utilities in DEB Packages

MariaDB's clients and utilities, libmysqlclient, and MariaDB Connector/C are dynamically linked with the system's OpenSSL library in .deb packages.

See Differences in MariaDB in Debian (and Ubuntu) for more information.

MariaDB Clients and Utilities in RPM Packages

MariaDB's clients and utilities, libmysqlclient, and MariaDB Connector/C are dynamically linked with the system's OpenSSL library in .rpm packages.

Updating Dynamically Linked OpenSSL Libraries on Linux

When the MariaDB Server or clients and utilities are dynamically linked to the system's OpenSSL library, it makes it very easy to update the libraries. The information below will show how to update these libraries for each platform.

Updating Dynamically Linked OpenSSL Libraries with yum/dnf

On RHEL, CentOS, Fedora, and other similar Linux distributions, it is highly recommended to update the libraries using yum or dnf. Starting with RHEL 8 and Fedora 22, `yum` has been replaced by `dnf`, which is the next major version of `yum`. However, `yum` commands still work on many systems that use `dnf`. Update the package by executing the following command:

```
sudo yum update openssl
```

Then restart MariaDB server and any clients or applications that use the library.

Updating Dynamically Linked OpenSSL Libraries with apt-get

On Debian, Ubuntu, and other similar Linux distributions, it is highly recommended to recommended to update the libraries using apt-get. First update the package cache by executing the following command:

```
sudo apt update
```

Then update the package by executing the following command:

```
sudo apt-get update openssl
```

Then restart MariaDB server and any clients or applications that use the library.

Updating Dynamically Linked OpenSSL Libraries with zypper

On SLES, OpenSUSE, and other similar Linux distributions, it is highly recommended to update the libraries using zypper. Update the package by executing the following command:

```
sudo zypper update openssl
```

Then restart MariaDB server and any clients or applications that use the library.

This page is licensed: CC BY-SA / Gnu FDL

Data-in-Transit Encryption

Protect your data as it moves across the network with Data-in-Transit Encryption. By leveraging the TLS (Transport Layer Security) protocol, MariaDB ensures that credentials, queries, and result sets are encrypted between the client and server. This prevents “man-in-the-middle” attacks and unauthorized eavesdropping on sensitive information.

This guide covers the essentials of securing your network traffic—from configuring SSL certificates and private keys to enforcing secure connections for all users. Secure your communications layer to maintain data integrity and confidentiality in any environment.

See Secure Connections Overview.

Conceptual overview of data-in-transit encryption in MariaDB, discussing supported TLS libraries (OpenSSL, wolfSSL), protocol versions (`tls_version`), and certificate verification.

See Securing Connections for Client and Server.

Complete MariaDB security guide. Complete resource for user management, access control, SSL/TLS encryption, and audit policies with comprehensive examples.

See Enabling TLS on MariaDB Server.

Secure, automatic SSL in MariaDB 11.4+ which is enabled by default and does not require any configuration

See Enabling TLS on MariaDB Server.

Step-by-step instructions for manual configuration of SSL in MariaDB via system variables like `ssl_cert` , `ssl_key` , and `ssl_ca` in the configuration file.

See Replication with Secure Connections.

A guide to securing replication traffic between primary and replica servers, covering the use of `CHANGE MASTER TO` options (e.g., `MASTER_SSL`) and mutual authentication.

See Certificate Creation with OpenSSL.

Complete OpenSSL TLS certificate guide: generate CA key/cert and server key/CSR, sign X509 with openssl x509 -CA/-CAkey, and verify certificates.

See SSL/TLS System Variables.

Reference list of system variables related to TLS configuration, such as `ssl_cipher`, `ssl_crl`, and `have_ssl`, used to manage and monitor encryption settings.

See Using TLSv1.3.

This page is licensed: CC BY-SA / Gnu FDL

Secure Connections Overview

Prior to MariaDB 11.4, by default, MariaDB transmits data between the server and clients without encrypting it. This is generally acceptable when the server and client run on the same host or in networks where security is guaranteed through other means. However, in cases where the server and client exist on separate networks or they are in a high-risk network, the lack of encryption does introduce security concerns as a malicious actor could potentially eavesdrop on the traffic as it is sent over the network between them.

To mitigate this concern, MariaDB allows you to encrypt data in transit between the server and clients using the Transport Layer Security (TLS) protocol. TLS was formerly known as Secure Socket Layer (SSL), but strictly speaking the SSL protocol is a predecessor to TLS and, that version of the protocol is now considered insecure. The documentation still uses the term SSL often and for compatibility reasons TLS-related server system and status variables still use the prefix `ssl_`, but internally, MariaDB only supports its secure successors.

Checking MariaDB Server for TLS Support

In order for MariaDB Server to use TLS, it needs to be compiled with TLS support. All MariaDB packages distributed by MariaDB Foundation and MariaDB Corporation are compiled with TLS support.

If you aren't sure whether your MariaDB Server binary was compiled with TLS support, then you can check the value of the have_ssl system variable. For example:

```
SHOW GLOBAL VARIABLES LIKE 'have_ssl';
+---------------+----------+
| Variable_name | Value    |
+---------------+----------+
| have_ssl      | DISABLED |
+---------------+----------+
```

The possible values are:

- If it is `DISABLED`, then the server was compiled with TLS support, but TLS is not enabled.
- If it is `YES`, then the server was compiled with TLS support, and TLS is enabled.
- If it is `NO`, then the server was not compiled with TLS support.

TLS Libraries

When MariaDB is compiled with TLS and cryptography support, it is usually either statically linked with MariaDB's bundled TLS and cryptography library, which might be wolfSSL or yaSSL, or dynamically linked with the system's TLS and cryptography library, which might be OpenSSL, GnuTLS, or Schannel.

See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.

TLS Protocol Versions

There are 4 versions of the TLS protocol:

- `TLSv1.0`
- `TLSv1.1`
- `TLSv1.2`
- `TLSv1.3`

Enabling Specific TLS Protocol Versions

In some cases, it might make sense to only enable specific TLS protocol versions. For example, it would make sense if your organization has to comply with a specific security standard. It would also make sense if a vulnerability is found in a specific TLS protocol version, and you would like to ensure that your server does not use the vulnerable protocol version.

The PCI DSS v3.2 recommends using a minimum protocol version of TLSv1.2.

On the **server** side, users can enable specific TLS protocol versions by setting the tls_version system variable. This system variable accepts a comma-separated list of TLS protocol versions. A TLS protocol version will only be enabled if it is present in this list. All other TLS protocol versions will not be permitted. This system variable can be specified as a command-line argument to mariadbd or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
tls_version = TLSv1.2,TLSv1.3
```

You can check which TLS protocol versions are enabled on a server by executing SHOW GLOBAL VARIABLES. For example:

```
SHOW GLOBAL VARIABLES LIKE 'tls_version';
```

On the **client** side, users can enable specific TLS protocol versions by setting the `--tls-version` option. This option accepts a comma-separated list of TLS protocol versions. A TLS protocol version will only be enabled if it is present in this list. All other TLS protocol versions will not be permitted. For example, to specify this option in a relevant client option group in an option file, you could set the following:

```
[client-mariadb]
tls_version = TLSv1.2,TLSv1.3
```

Or if you wanted to specify it on the command-line with the mariadb client, then you could execute something like this:

```
$ mariadb -u myuser -p -h myserver.mydomain.com \
   --ssl \
   --tls-version="TLSv1.2,TLSv1.3"
```

TLS Protocol Version Support

The TLS protocol versions that are supported depend on the underlying TLS library used by the specific MariaDB binary.

TLS Library	Supported TLS Protocol Versions
openSSL	TLSv1, TLSv1.1, TLSv1.2, TLSv1.3
wolfSSL	TLSv1, TLSv1.1, TLSv1.2, TLSv1.3
yaSSL	TLSv1, TLSv1.1
Schannel	TLSv1, TLSv1.1, TLSv1.2
GnuTLS	TLSv1, TLSv1.1, TLSv1.2, TLSv1.3

See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used by the server and by clients on each platform.

TLS Protocol Version Support in OpenSSL

MariaDB binaries built with the OpenSSL library (OpenSSL 1.0.1 or later) support TLSv1.1 and TLSv1.2.

MariaDB binaries built with the OpenSSL library (OpenSSL 1.1.1 or later) support TLSv1.3.

If your MariaDB Server binary is built with OpenSSL, then you can set the ssl_cipher system variable to values like `SSLv3` or `TLSv1.2` to allow all SSLv3.0 or all TLSv1.2 ciphers. However, this does not necessarily limit the protocol version to TLSv1.2. See MDEV-14101 for more information about that.

Note that the `TLSv1.3` ciphers cannot be excluded when using OpenSSL, even by using the ssl_cipher system variable. See Using TLSv1.3 for details.

SSLv3.0 is known to be vulnerable to the POODLE attack, so it should not be used. SSLv2.0 and SSLv3.0 are disabled for MariaDB Server binaries linked with OpenSSL.

TLS Protocol Version Support in wolfSSL

MariaDB binaries built with the bundled wolfSSL library support TLSv1.0, TLSv1.1, TLSv1.2, and TLSv1.3.

TLS Protocol Version Support in yaSSL

MariaDB binaries built with the bundled yaSSL library support SSLv3.0, TLSv1.0, and TLSv1.1.

SSLv3.0 is known to be vulnerable to the POODLE attack, so it should not be used. SSLv2.0 and SSLv3.0 are disabled for MariaDB Server binaries linked with yaSSL.

TLS Protocol Version Support in Schannel

MariaDB binaries built with the Schannel library support different versions of TLS on different versions of Windows. See the Protocols in TLS/SSL (Schannel SSP) documentation from Microsoft to determine which versions of TLS are supported on each version of Windows.

TLS Protocol Version Support in GnuTLS

MariaDB binaries built with the GnuTLS library support TLSv1.0, TLSv1.1, TLSv1.2, and TLSv1.3.

Enabling TLS

See Securing Connections for Client and Server for information on how to enable TLS on the client and server.

Certificate Verification

Certificate verification is how TLS authenticates its connections by verifying that it is talking to who it says it is. There are multiple components to this verification process:

- Was the certificate signed by a trusted Certificate Authority (CA)?
- Is the certificate expired?
- Is the certificate on my Certificate Revocation List (CRL)?
- Does the certificate belong to who I believe that I'm communicating with?

Certificate Authorities (CAs)

Certificate Authorities (CAs) are entities that you trust to sign TLS certificates. Your organization might have its own internal CA, or it might use trusted third-party CAs.

CAs are specified on the server and client by using the ssl_ca and ssl_capath options.

The ssl_ca option defines a path to a PEM file that should contain one or more X509 certificates for trusted Certificate Authorities (CAs). This option requires that you use the absolute path, not a relative path.

The ssl_capath option defines a path to a directory that contains one or more PEM files that should each contain one X509 certificate for a trusted Certificate Authority (CA). This option requires that you use the absolute path, not a relative path. The ssl_capath option is only supported if the server or client was built with OpenSSL, wolfSSL, or yaSSL. If the client was built with GnuTLS or Schannel, then the ssl_capath option is not supported.

See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.

The directory specified by ssl_capath needs to be run through the openssl rehash command. For example, if the following is configured:

```
ssl_capath=/etc/my.cnf.d/certificates/ca/
```

Then execute the following command:

```
openssl rehash /etc/my.cnf.d/certificates/ca/
```

Requiring a Specific Certificate Authority (CA)

The server can require a specific Certificate Authority (CA) for a client if the client's user account has been defined with `REQUIRE ISSUER`. See Securing Connections for Client and Server: Requiring TLS for more information.

Certificate Revocation Lists (CRLs)

Certificate Revocation Lists (CRLs) are lists of certificates that have been revoked by the Certificate Authority (CA) before they were due to expire.

CRLs are specified on the server and client by using the ssl_crl and ssl_crlpath options.

The ssl_crl option defines a path to a PEM file that should contain one or more X509 revoked certificates. This option requires that you use the absolute path, not a relative path. For servers, the ssl_crl option is only valid if the server was built with OpenSSL. If the server was built with wolfSSL or yaSSL, then the ssl_crl option is not supported. For clients, the ssl_crl option is only valid if the client was built with OpenSSL or Schannel. Likewise, if the client was built with GnuTLS, wolfSSL or yaSSL, then the ssl_crl option is not supported.

The ssl_crlpath option defines a path to a directory that contains one or more PEM files that should each contain one revoked X509 certificate. This option requires that you use the absolute path, not a relative path. The ssl_crlpath option is only supported if the server or client was built with OpenSSL. If the server was built with wolfSSL or yaSSL, then the ssl_crlpath option is not supported. Likewise, if the client was built with GnuTLS, Schannel, wolfSSL, or yaSSL, then the ssl_crlpath option is not supported.

See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.

The directory specified by ssl_crlpath needs to be run through the openssl rehash command. For example, if the following is configured:

```
ssl_crlpath=/etc/my.cnf.d/certificates/crl/
```

Then execute the following command:

```
openssl rehash /etc/my.cnf.d/certificates/crl/
```

Server Certificate Verification

Normally the TLS implementation performs numerous checks to verify whether the certificate is valid. It should be within its validity period, not revoked, signed by a trusted certificate authority, belong to the host that uses it.

Clients and utilities enable all these checks by default. Last two checks can be disabled with an option, such as `disable-ssl-verify-server-cert`. Before MariaDB 11.3, all server certificate verification checks were disabled by default, and could be enabled with the `ssl-verify-server-cert` option.

To verify whether the server's certificate belong to server's host, clients and utilities will check the **Common Name (CN)** attribute located in the **Subject** field of the certificate against the server's host name and IP address. If the **Common Name (CN)** matches either of those, then the certificate is verified.

Server Certificate Verification with Subject Alternative Names (SANs)

The **Subject Alternative Name (SAN)** field, which is an X.509v3 extension, can also be used for server certificate verification, if it is present in the server certificate. This field is also sometimes called **subjectAltName**. When using a client or utility that supports server certificate verification with **subjectAltName** fields, if the server certificate contains any **subjectAltName** fields, then those fields will also be checked against the server's host name and IP address.

Whether server certificate verification with **subjectAltName** fields is supported depends on the underlying TLS library used by the client or utility.

See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.

SAN Support with OpenSSL, wolfSSL, and yaSSL

For clients and utilities built with OpenSSL (OpenSSL 1.0.2 or later), support for server certificate verification with **subjectAltName** fields that contain the server's **host name** was added.

For clients and utilities built with OpenSSL (OpenSSL 1.0.2 or later), support for server certificate verification with **subjectAltName** fields that contain the server's **IP address** was added.

This support also applies to other TLS libraries that use OpenSSL's API. In OpenSSL's API, server certificate verification with **subjectAltName** fields depends on the X509_check_host and X509_check_ip functions. These functions are supported in the following TLS libraries:

- OpenSSL 1.0.2 or later
- wolfSSL

And they are **not** supported in the following TLS libraries:

- yaSSL

MariaDB's RPM packages were built with OpenSSL 1.0.1 on RHEL 7 and CentOS 7, even after OpenSSL 1.0.2 became available on those distributions. As a side effect, the clients and utilities bundled in these packages did not support server certificate verification with the **subjectAltName** field, even if the packages were installed on a system that had OpenSSL 1.0.2 installed. MariaDB's RPM packages on RHEL 7 and CentOS 7 are built with OpenSSL 1.0.2.

SAN Support with Schannel

For clients and utilities linked with Schannel, support for server certificate verification with **subjectAltName** fields was added in MariaDB Connector/C 3.0.2. See CONC-250 for more information.

SAN Support with GnuTLS

For clients and utilities linked with GnuTLS, support for server certificate verification with **subjectAltName** fields was added in MariaDB Connector/C 3.0.0. See CONC-250 for more information.

Client Certificate Verification

The server verifies a client certificate by checking the client's known `SUBJECT` against the **Subject** attribute in the client's certificate. This is only done for user accounts that have been defined with `REQUIRE SUBJECT`. See Securing Connections for Client and Server: Requiring TLS for more information.

Securing Connections for Client and Server

Starting from 11.4 MariaDB, it encrypts the transmitted data between the server and clients by default unless the server and client run on the same host.

Before that the default behavior was to transmit the data unencrypted over the network introducing a security concerns as a malicious actor could potentially eavesdrop on the traffic as it is sent over the network between them.

The data in transit are encrypted (by default or if enabled manually) using the Transport Layer Security (TLS) protocol. TLS was formerly known as Secure Socket Layer (SSL), but strictly speaking the SSL protocol is a predecessor to TLS and, that version of the protocol is now considered insecure. The documentation still uses the term SSL often and for compatibility reasons TLS-related server system and status variables still use the prefix `ssl_`, but internally, MariaDB only supports its secure successors.

Enabling TLS

Enabling TLS for MariaDB Server

> **CURRENT**
>
> MariaDB enables TLS automatically. Certificates are generated on startup and only stored in memory. Certificate verification is enabled by default on the client side and certificates are verified if the authentication plugin itself is MitM safe (`mysql_native_password`, `ed25519`, `parsec`).
>
> **< 11.4**
>
> In order to enable TLS in a MariaDB server, you need to generate TLS certificates and configure the server to use them.
>
> To do that there are a number of system variables that you need to set, such as:
>
> - You need to set the path to the server's X509 certificate by setting the ssl_cert system variable.
> - You need to set the path to the server's private key by setting the ssl_key system variable.

- Unless you use a certificate which was signed by a trusted certificate authority (CA) you need to set the path to the certificate authority chain that can verify the server's certificate by setting either the ssl_ca or the ssl_capath system variables.
- If you want to restrict the server to certain ciphers, then you also need to set the ssl_cipher system variable.

For example, to set these variables for the server, add the system variables to a relevant server option group in an option file:

```
[mariadb]
...
ssl_cert = /etc/my.cnf.d/certificates/server-cert.pem
ssl_key = /etc/my.cnf.d/certificates/server-key.pem
ssl_ca = /etc/my.cnf.d/certificates/ca.pem
```

And then restart the server to make the changes persistent.

Once the server is back up, you can check that TLS is enabled by checking the value of the have_ssl system variable. For example:

```
SHOW VARIABLES LIKE 'have_ssl';

+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| have_ssl      | YES   |
+---------------+-------+
```

Reloading the Server's Certificates and Keys Dynamically

The `FLUSH SSL` command can be used to dynamically reinitialize the server's TLS context.

See FLUSH SSL for more information.

Enabling TLS for MariaDB Clients

Different clients and utilities may use different methods to enable TLS. You can let the client to use TLS without specifying client-side certificate — this is called a **one-way TLS** below — to have the connection encrypted. Or you can additionally provide client-side certificate — this is **two-way TLS** — which will allow the server to do the certificate based client authentication.

Enabling One-Way TLS for MariaDB Clients

One-way TLS means that only the server provides a private key and an X509 certificate. When TLS is used without a client certificate, it is called "one-way" TLS, because only the server can be authenticated, so certificate based authentication is only possible in one direction. However, encryption is still possible in both directions. Server certificate verification means that the client verifies that the certificate belongs to the server.

MariaDB starting with 11.4

Starting from MariaDB 11.4 (Connector/C version 3.4) this mode is enabled by default. Connector/C will enable TLS automatically on all non-local connections and will require a verified server certificate to prevent man-in-the-middle attacks.

To enable one-way TLS manually (for older clients or if you want verification with CA certificate) you can specify these options in a relevant client option group in an option file:

```
[client-mariadb]
ssl_ca = /etc/my.cnf.d/certificates/ca.pem
ssl-verify-server-cert
```

Or if you wanted to specify them on the command-line with the mariadb client, then you could execute something like this:

```
$ mariadb -u myuser -p -h myserver.mydomain.com \
   --ssl-ca=/etc/my.cnf.d/certificates/ca.pem \
   --ssl-verify-server-cert
```

You can disable server certificate verification by configuring this:

```
[client-mariadb]
disable-ssl-verify-server-cert
```

(or a similar command line option), but it creates a risk of a man-in-the-middle attack where the connection can be eavesdropped or manipulated even if it is being encrypted.

Enabling Two-Way TLS for MariaDB Clients

Two-way TLS means that both the client and server provide a private key and an X509 certificate. It is called "two-way" TLS because both the client and server can be authenticated.

For example, to specify these options in a relevant client option group in an option file, you could set the following:

```
[client-mariadb]
ssl_cert = /etc/my.cnf.d/certificates/client-cert.pem
ssl_key = /etc/my.cnf.d/certificates/client-key.pem
ssl_ca = /etc/my.cnf.d/certificates/ca.pem
ssl-verify-server-cert
```

Or if you wanted to specify them on the command-line with the mariadb client, then you could execute something like this:

```
$ mariadb -u myuser -p -h myserver.mydomain.com \
   --ssl-cert=/etc/my.cnf.d/certificates/client-cert.pem \
   --ssl-key=/etc/my.cnf.d/certificates/client-key.pem \
   --ssl-ca=/etc/my.cnf.d/certificates/ca.pem \
   --ssl-verify-server-cert
```

Two-way SSL is required for an account if the `REQUIRE X509`, `REQUIRE SUBJECT`, and/or `REQUIRE ISSUER` clauses are specified for the account.

Enabling TLS for MariaDB Connector/C Clients

See the documentation on MariaDB Connector/C's TLS Options for information on how to enable TLS for clients that use MariaDB Connector/C.

Enabling TLS for MariaDB Connector/ODBC Clients

See the documentation on MariaDB Connector/ODBC's TLS-Related Connection Parameters for information on how to enable TLS for clients that use MariaDB Connector/ODBC.

Enabling TLS for MariaDB Connector/J Clients

See the documentation on Using TLS/SSL with MariaDB Connector/J for information on how to enable TLS for clients that use MariaDB Connector/J.

Verifying that a Connection is Using TLS

You can verify that a connection is using TLS by checking the connection's Ssl_version status variable. It will either show the TLS version used, or be empty when no encryption is in effect. For example:

```
SHOW SESSION STATUS LIKE 'Ssl_version';
+---------------+-------------------------+
| Variable_name | Value                   |
+---------------+-------------------------+
| Ssl_version   | TLSv1.3                 |
+---------------+-------------------------+
1 row in set (0.00 sec)
```

Requiring TLS for Specific User Accounts

You can set certain TLS-related restrictions for specific user accounts. For instance, you might use this with user accounts that require access to sensitive data while sending it across networks that you do not control. These restrictions can be enabled for a user account with the CREATE USER, ALTER USER, or GRANT statements. For example:

- A user account must connect via TLS if the user account is defined with the `REQUIRE SSL` clause.

```
ALTER USER 'alice'@'%'
   REQUIRE SSL;
```

- A user account must connect via TLS with a specific cipher if the user account is defined with the `REQUIRE CIPHER` clause.

```
ALTER USER 'alice'@'%'
   REQUIRE CIPHER 'ECDH-RSA-AES256-SHA384';
```

- A user account must connect via TLS with a valid client certificate if the user account is defined with the `REQUIRE X509` clause.

```
ALTER USER 'alice'@'%'
   REQUIRE X509;
```

- A user account must connect via TLS with a specific client certificate if the user account is defined with the `REQUIRE SUBJECT` clause.

```
ALTER USER 'alice'@'%'
   REQUIRE SUBJECT '/CN=alice/O=My Dom, Inc./C=US/ST=Oregon/L=Portland';
```

- A user account must connect via TLS with a client certificate that must be signed by a specific certificate authority if the user account is defined with the `REQUIRE ISSUER` clause.

```
ALTER USER 'alice'@'%'
   REQUIRE SUBJECT '/CN=alice/O=My Dom, Inc./C=US/ST=Oregon/L=Portland'
   AND ISSUER '/C=FI/ST=Somewhere/L=City/ O=Some Company/CN=Peter
Parker/emailAddress=p.parker@marvel.com';
```

Requiring TLS for Specific User Accounts from Specific Hosts

A user account can have different definitions depending on what host the user account is logging in from. Therefore, it is possible to have different TLS requirements for the same username for different hosts. For example:

```
CREATE USER 'alice'@'localhost'
   REQUIRE NONE;

CREATE USER 'alice'@'%'
   REQUIRE SUBJECT '/CN=alice/O=My Dom, Inc./C=US/ST=Oregon/L=Portland'
   AND ISSUER '/C=FI/ST=Somewhere/L=City/ O=Some Company/CN=Peter
Parker/emailAddress=p.parker@marvel.com'
   AND CIPHER 'ECDHE-ECDSA-AES256-SHA384';
```

In the above example, the `alice` user account does not require TLS when logging in from localhost. However, when the `alice` user account logs in from any other host, they must use TLS with the given cipher, and they must provide a valid client certificate with the given subject that must have been signed by the given issuer.

Zero-Configuration SSL

> **Note:**
>
> This feature is available from MariaDB 11.4.

Zero-Configuration SSL (TLS)

Zero-Configuration SSL is a feature that makes encrypted connections the default standard without requiring manual certificate management. This allows for secure, MitM[27]-resistant connections "out of the box", by automating server certificate generation and client-side verification.

Overview

Traditionally, enabling SSL/TLS required manual steps: generating private keys, creating Certificate Signing Requests (CSRs), and managing a Certificate Authority (CA). Because of this complexity, many deployments remained unencrypted.

Zero-Configuration SSL eliminates these barriers:

1. Automatic Server Setup: The server automatically generates a self-signed certificate if no certificate is configured.
2. Zero-trust validation: Clients verify the server's identity using the existing account password as a shared secret, rather than relying on a trusted CA.

Requirements and Defaults

- MariaDB Version: Server and Client must be version 11.4 or higher.
- Default Behavior: SSL is enabled and verified by default. The client has `--ssl-verify-server-cert` enabled by default.
- Supported Authentication Plugins: This feature works with mysql_native_password, ed25519, and parsec (that are MitM-proof even without SSL).

Configuration Options

While designed to work automatically, the following options allow for manual control:

Option	Description
`--disable-ssl`	Disables SSL entirely (not recommended).
`--skip-ssl-verify-server-cert`	A verified certificate is not required, the client will accept unverified certificates or even a completely unencrypted connection. This is not MitM-safe, even if the server uses SSL.

Limitations

Authentication plugins such as PAM, GSSAPI, and `cached_sha2_plugin` are not MitM-proof without SSL, they require SSL to be secure and thus cannot be used to verify SSL itself. One should use traditional CA-based verification with these plugins.

Verification

To verify that Zero-Configuration SSL is being used, connect via TCP/IP (not via UNIX socket, because in that case the certificate is automatically trusted), and look at the status output:

```
mariadb -h 127.0.0.1 -u <username> -p
...
MariaDB [(none)]> status
--------------
mariadb from 12.2.2-MariaDB, client 15.2 for osx10.20 (arm64) using  EditLine wrapper
...
Current user:       stefan@localhost
SSL:            Cipher in use is TLS_AES_256_GCM_SHA384, cert is OK
...
Connection:     127.0.0.1 via TCP/IP
...
TCP port:       3306
...
```

Check if the server has automatically generated its own certificates by querying the session variables:

```
MariaDB [(none)]> SHOW SESSION STATUS LIKE 'Ssl_cipher'; SHOW SESSION STATUS LIKE 'Ssl_version';
+---------------+------------------------+
| Variable_name | Value                  |
+---------------+------------------------+
| Ssl_cipher    | TLS_AES_256_GCM_SHA384 |
+---------------+------------------------+
...
+---------------+---------+
| Variable_name | Value   |
+---------------+---------+
| Ssl_version   | TLSv1.3 |
+---------------+---------+
```

Run the following to see the server's certificate details:

```
$ openssl s_client -starttls mysql 127.0.0.1:3306
Connecting to 127.0.0.1
CONNECTED(00000003)
Can't use SSL_get_servername
depth=0 CN=MariaDB Server
verify error:num=18:self-signed certificate
verify return:1
depth=0 CN=MariaDB Server
verify return:1
---
Certificate chain
 0 s:CN=MariaDB Server
   i:CN=MariaDB Server
   a:PKEY: RSA, 4096 (bit); sigalg: sha256WithRSAEncryption
   v:NotBefore: Mar  2 16:19:15 2026 GMT; NotAfter: Feb 28 16:19:15 2036 GMT
...
```

How it Works

The core mechanism of Zero-Configuration SSL is the use of the user password as a shared secret to verify the server's identity without a Certificate Authority (CA).

1. Connection Establishment: The client connects and establishes a TLS connection using the server's self-signed certificate.
2. Fingerprint Calculation: The client calculates the SHA256 fingerprint of the server's certificate.
3. Signature Generation:
    - The client creates a signature based on the certificate fingerprint and the user's password.

- The server performs the same calculation.

4. Verification: By comparing these values, the client confirms it is communicating with the intended server. This prevents Man-in-the-Middle (MitM) attacks because an attacker would present a different certificate, resulting in a fingerprint mismatch that they cannot resolve without knowing the user's password.

This page is licensed: CC BY-SA / Gnu FDL

Replication with Secure Connections

> **Note:**
>
> The terms *master* and *slave* have historically been used in replication, and MariaDB has begun the process of adding *primary* and *replica* synonyms. The old terms will continue to be used to maintain backward compatibility - see MDEV-18777 to follow progress on this effort.

Overview

By default, MariaDB replicates data between primaries and replicas without encrypting it. This is generally acceptable when the primary and replica run are in networks where security is guaranteed through other means. However, in cases where the primary and replica exist on separate networks or they are in a high-risk network, the lack of encryption does introduce security concerns as a malicious actor could potentially eavesdrop on the traffic as it is sent over the network between them.

To mitigate this concern, MariaDB allows you to encrypt replicated data in transit between primaries and replicas using the Transport Layer Security (TLS) protocol. TLS was formerly known as Secure Socket Layer (SSL), but strictly speaking the SSL protocol is a predecessor to TLS and, that version of the protocol is now considered insecure. The documentation still uses the term SSL often and for compatibility reasons TLS-related server system and status variables still use the prefix `ssl_`, but internally, MariaDB only supports its secure successors.

In order to secure connections between the primary and replica, you need to ensure that both servers were compiled with TLS support. See Secure Connections Overview to determine how to check whether a server was compiled with TLS support.

You also need an X509 certificate, a private key, and the Certificate Authority (CA) chain to verify the X509 certificate for the primary. If you want to use two-way TLS, then you will also an X509 certificate, a private key, and the Certificate Authority (CA) chain to verify the X509 certificate for the replica. If you want to use self-signed certificates that are created with OpenSSL, then see Certificate Creation with OpenSSL for information on how to create those.

Securing Replication Traffic

In order to secure replication traffic, you will need to ensure that TLS is enabled on the primary. If you want to use two-way TLS, then you will also need to ensure that TLS is enabled on the replica. See Securing Connections for Client and Server for information on how to do that.

For example, to set the TLS system variables for each server, add them to a relevant server option group in an option file on each server:

```
[mariadb]
ssl_cert = /etc/my.cnf.d/certificates/server-cert.pem
ssl_key = /etc/my.cnf.d/certificates/server-key.pem
ssl_ca = /etc/my.cnf.d/certificates/ca.pem
```

And then restart the server to make the changes persistent.

At this point, you can reconfigure the replicas to use TLS to encrypt replicated data in transit. There are two methods available to do this:

- Executing the CHANGE MASTER statement to set the relevant TLS options.
- Setting TLS client options in an option file.

Enabling TLS on a Replica

TLS can be enabled on a replication replica by issuing the CHANGE MASTER statement, while setting a number of options. Which options you set depends on whether you want one-way TLS or two-way TLS, and whether or not you want to verify the server certificate.

Enabling Two-Way TLS

Two-way TLS means that both the client and server provide a private key and an X509 certificate. It is called "two-way" TLS because both the client and server can be authenticated. In this case, the "client" is the replica. To configure two-way TLS, you would need to set the following options:

- You need to set the path to the server's certificate by setting the MASTER_SSL_CERT option.
- You need to set the path to the server's private key by setting the MASTER_SSL_KEY option.
- You need to set the path to the certificate authority (CA) chain that can verify the server's certificate by setting either the MASTER_SSL_CA or the MASTER_SSL_CAPATH options.
- If you want server certificate verification, then you also need to set the MASTER_SSL_VERIFY_SERVER_CERT option (enabled by default from MariaDB 11.3).
- If you want to restrict the server to certain ciphers, then you also need to set the MASTER_SSL_CIPHER option.

If the replica threads are currently running, you first need to stop them by executing the STOP SLAVE statement. For example:

```
STOP SLAVE;
```

Then, execute the CHANGE MASTER statement to configure the replica to use TLS. For example:

```
CHANGE MASTER TO
   MASTER_SSL_CERT = '/path/to/client-cert.pem',
   MASTER_SSL_KEY = '/path/to/client-key.pem',
   MASTER_SSL_CA = '/path/to/ca/ca.pem',
   MASTER_SSL_VERIFY_SERVER_CERT=1;
```

At this point, you can start replication by executing the START SLAVE statement. For example:

```
START SLAVE;
```

The replica now uses TLS to encrypt data in transit as it replicates it from the primary.

Enabling One-Way TLS

Enabling One-Way TLS With Server Certificate Verification

One-way TLS means that only the server provides a private key and an X509 certificate. When TLS is used without a client certificate, it is called "one-way" TLS, because only the server can be authenticated, so authentication is only possible in one direction. However, encryption is still possible in both directions. Server certificate verification means that the client verifies that the certificate belongs to the server. In this case, the "client" is the replica. This mode is enabled by default starting from MariaDB 11.3. To configure one-way TLS in earlier versions, you would need to set the following options:

- You need to set the path to the certificate authority (CA) chain that can verify the server's certificate by setting either the MASTER_SSL_CA or the MASTER_SSL_CAPATH options.
- You need to set the MASTER_SSL_VERIFY_SERVER_CERT option.

- If you want to restrict the server to certain ciphers, then you also need to set the MASTER_SSL_CIPHER option.

If the replica threads are currently running, you first need to stop them by executing the STOP SLAVE statement. For example:

```
STOP SLAVE;
```

Then, execute the CHANGE MASTER statement to configure the replica to use TLS. For example:

```
CHANGE MASTER TO
   MASTER_SSL_CA = '/path/to/ca/ca.pem',
   MASTER_SSL_VERIFY_SERVER_CERT=1;
```

At this point, you can start replication by executing the START SLAVE statement. For example:

```
START SLAVE;
```

The replica now uses TLS to encrypt data in transit as it replicates it from the primary.

Enabling One-Way TLS Without Server Certificate Verification

One-way TLS means that only the server provides a private key and an X509 certificate. When TLS is used without a client certificate, it is called “one-way” TLS, because only the server can be authenticated, so authentication is only possible in one direction. However, encryption is still possible in both directions. In this case, the “client” is the replica. To configure two-way TLS without server certificate verification, you would need to set the following options:

- You need to configure the replica to use TLS by setting the MASTER_SSL option.
- If you want to restrict the server to certain ciphers, then you also need to set the MASTER_SSL_CIPHER option.
- Starting from MariaDB 11.3 you need to disable the MASTER_SSL_VERIFY_SERVER_CERT option.

If the replica threads are currently running, you first need to stop them by issuing the STOP REPLICA statement:

```
STOP REPLICA;
```

Then, execute the CHANGE MASTER statement to configure the replica to use TLS. For example:

```
CHANGE MASTER TO
   MASTER_SSL=1, MASTER_SSL_VERIFY_SERVER_CERT=0;
```

Now start replication by issuing the START REPLICA statement:

```
START REPLICA;
```

The replica now uses TLS to encrypt data in transit as it replicates from the primary.

Setting TLS Client Options in an Option File

In cases where you don’t mind restarting the server or you are setting the server up from scratch for the first time, you may find it more convenient to configure TLS options for replication through an option file. This is done the same way as it is for other clients. The specific options that you would need to set would depend on whether you want one-way TLS or two-way TLS, and whether you want to verify the server certificate. See Securing Connections for Client and Server: Enabling TLS for MariaDB Clients for more information.

To enable two-way TLS with server certificate verification, you can specify the following options in a relevant client option group in an option file:

```
[client-mariadb]
ssl_cert = /etc/my.cnf.d/certificates/client-cert.pem
ssl_key = /etc/my.cnf.d/certificates/client-key.pem
ssl_ca = /etc/my.cnf.d/certificates/ca.pem
ssl-verify-server-cert
```

Before restarting the server, you may also want to set the –skip-slave-start option in a server option group in an option file. This option prevents the replica threads from restarting automatically when the server starts. Instead, they will have to be restarted manually.

After these changes have been made, you can restart the server.

Once the server is back online, set the MASTER_SSL option by executing the CHANGE MASTER statement. This enables TLS. For example:

```
CHANGE MASTER TO MASTER_SSL=1;
```

The certificate and keys are read from the option file. At this point, you can start replication by issuing the START REPLICA statement:

```
START REPLICA;
```

Enabling TLS on MariaDB Server

Overview

MariaDB Server supports data-in-transit encryption, which secures data transmitted over the network. The server and the clients encrypt data using the Transport Layer Security (TLS) protocol, which is a newer version of the Secure Socket Layer (SSL) protocol.

TLS must be manually enabled on the server, which is what this page describes.

Enabling TLS

> **Step 1**
>
> **Acquire an X509 certificate and a private key for the server.**
>
> If it is a test or development server, self-signed certificates and keys should be sufficient.

Step 2

Determine which system variables and you need to configure.

Mandatory system variables and options for TLS include:

System Variable/Option	Description
ssl_cert	X509 cert in PEM format
ssl_key	X509 key in PEM format
ssl_ca	JCA file in PEM format

Other useful system variables and options for TLS include:

System Variable/Option	Description
require_secure_transport	When this option is enabled, connections attempted using insecure transport are rejected. Secure transports are SSL/TLS, Unix sockets, and named pipes.
ssl_capath	CA directory
ssl_cipher	SSL cipher to use
ssl_crl	CRL file in PEM format
ssl_crlpath	CRL directory
tls_version	TLS protocol version for secure connections

Step 3

Choose a configuration file in which to configure your system variables and options.

It is not recommended to make changes to one of the bundled configuration files. Instead, we recommend to create a custom configuration file in one of the directories included by the main configuration file (for instance, my.cnf). Configuration files in included directories are read in alphabetical order. If you want your custom configuration file to override the bundled configuration files, it is a good idea to prefix the custom configuration file's name with a string that will be sorted last, such as `z-`. Examples:

- RHEL, CentOS, Rocky Linux, and SLES: `/etc/my.cnf.d/z-custom-my.cnf`
- Debian and Ubuntu: `/etc/mysql/mariadb.conf.d/z-custom-my.cnf`
- macOS: `/opt/homebrew/etc/z-custom-my.cnf`

Step 4

Set your system variables and options in the configuration file.

They need to be set in a group that is read by MariaDB Server, such as `[mariadb]`, `[server]`, or `[client-server]`:

```
[mariadb]
ssl_cert = /certs/server-cert.pem
ssl_key = /certs/server-key.pem
ssl_ca = /certs/ca-cert.pem
```

Step 5

Restart the server.

On most Linux systems, run this command:

```
sudo systemctl restart mariadb
```

On macOS, run this command:

```
brew services restart mariadb
```

Step 6

Connect to the server.

Start a client like mariadb (see this page for connection options):

```
$ sudo mariadb
```

Step 7

Verify that TLS is enabled.

```
SHOW GLOBAL VARIABLES LIKE 'have_ssl';
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| have_ssl      | YES   |
+---------------+-------+
```

Certificate Creation with OpenSSL

Warning:

The instructions below generate version 1 certificates only. These work fine with servers and clients using OpenSSL, but fail if WolfSSL is used instead, as is the case for our Windows MSI packages and our binary tarballs for Linux.

WolfSSL requires version 3 certificates instead when using TLS v1.2 or higher, and so won't work with certificates generated as shown here when using two-way TLS with explicit client certificates.

Generating version 3 certificates requires a few more steps. See also: MDEV-25701

In order to secure communications with the MariaDB Server using TLS, you need to create a private key and an X509 certificate for the server. You may also want to create additional private keys and X509 certificates for any clients that need to connect to the server with TLS. This guide covers how to create a private key and a self-signed X509 certificate with OpenSSL.

Certificate Creation

The OpenSSL library provides a command-line tool called openssl, which can be used for performing various tasks with the library, such as generating private keys, creating X509 certificate requests, signing X509 certificates as a Certificate Authority (CA), and verifying X509 certificates.

Creating a Certificate Authority Private Key and Certificate

The Certificate Authority (CA) is typically an organization (such as Let's Encrypt) that signs the X509 certificate and validates ownership of the domain. However, when you would like to use self-signed certificates, you need to create the private key and certificate for the CA yourself, and then you can use them to sign your own X509 certificates.

To start, generate a private key for the CA using the openssl genrsa command. For example:

```
# openssl genrsa 2048 > ca-key.pem
```

After that, you can use the private key to generate the X509 certificate for the CA using the openssl req command. For example:

```
# openssl req -new -x509 -nodes -days 365000 \
      -key ca-key.pem -out ca.pem
```

The above commands create two files in the working directory: The `ca-key.pem` private key and the `ca.pem` X509 certificate are both are used by the CA to create self-signed X509 certificates below.

Creating a Private Key and a Self-Signed Certificate

Once you have the CA's private key and X509 certificate, you can create the self-signed X509 certificates to use for the MariaDB Server, client, replication and other purposes.

To start, generate a private key and create a certificate request using the openssl req command. For example:

```
# openssl req -newkey rsa:2048 -days 365000 \
      -nodes -keyout server-key.pem -out server-req.pem
```

After that, process the key to remove the passphrase using the openssl rsa command. For example:

```
# openssl rsa -in server-key.pem -out server-key.pem
```

Lastly, using the certificate request and the CA's private key and X509 certificate, you can generate a self-signed X509 certificate from the certificate request using the openssl x509 command. For example:

```
# openssl x509 -req -in server-req.pem -days 365000 \
      -CA ca.pem -CAkey ca-key.pem -set_serial 01 \
      -out server-cert.pem
```

This creates a `server-cert.pem` file, which is the self-signed X509 certificate.

Certificate Verification

Once you have created the CA's X509 certificate and a self-signed X509 certificate, you can verify that the X509 certificate was correctly generated using the openssl verify command. For example:

```
# openssl verify -CAfile ca.pem server-cert.pem
server-cert.pem: OK
```

You can add as many X509 certificates to check against the CA's X509 certificate as you want to verify. A value of `OK` indicates that you can use it was correctly generated and is ready for use with MariaDB.

SSL/TLS System Variables

The system variables listed on this page relate to encrypting data during transfer between servers and clients using the Transport Layer Security (TLS) protocol. Often, the term Secure Sockets Layer (SSL) is used interchangeably with TLS, although strictly speaking the SSL protocol is the predecessor of TLS and is no longer considered secure.

For compatibility reasons, the TLS system variables in MariaDB still use the `ssl_` prefix, but MariaDB only supports its more secure successors. For more information on SSL/TLS in MariaDB, see Secure Connections Overview.

Variables

`have_openssl`

- Description: This variable shows whether the server is linked with OpenSSL rather than MariaDB's bundled TLS library, which might be wolfSSL or yaSSL.
  - I this system variable shows `YES`, the server is linked with OpenSSL.
  - See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.
- Scope: Global
- Dynamic: No

`have_ssl`

- Description: This variable shows whether the server supports using TLS to secure connections.
  - If the value is `YES`, then the server supports TLS, and TLS is enabled.
  - If the value is `DISABLED`, then the server supports TLS, but TLS is not enabled.
  - If the value is `NO`, then the server was not compiled with TLS support, so TLS cannot be enabled.
  - When TLS is supported, check the have_openssl system variable to determine whether the server is using OpenSSL or MariaDB's bundled TLS library. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.
- Scope: Global
- Dynamic: No

`ssl_ca`

- Description: Defines a path to a PEM file that should contain one or more X509 certificates for trusted Certificate Authorities (CAs) to use for TLS. This system variable requires that you use the absolute path, not a relative path. This system variable implies the ssl option.
  - See Secure Connections Overview: Certificate Authorities (CAs) for more information.
- Command line: `--ssl-ca=file_name`
- Scope: Global
- Dynamic: No
- Data Type: `file name`

`ssl_capath`

- Description: Defines a path to a directory that contains one or more PEM files that should each contain one X509 certificate for a trusted Certificate Authority (CA) to use for TLS. This system variable requires that you use the absolute path, not a relative path. The directory specified by this variable needs to be run through the openssl rehash command. This system variable implies the ssl option.
  - See Secure Connections Overview: Certificate Authorities (CAs) for more information.
- Command line: `--ssl-capath=directory_name`
- Scope: Global
- Dynamic: No
- Data Type: `directory name`

`ssl_cert`

- Description: Defines a path to the X509 certificate file to use for TLS. This system variable requires that you use the absolute path, not a relative path. This system variable implies the ssl option.

- Command line: `--ssl-cert=name`
- Scope: Global
- Dynamic: No
- Data Type: `file name`
- Default Value: None

`ssl_cipher`

- Description: List of permitted ciphers or cipher suites to use for TLS. Besides cipher names, if MariaDB was compiled with OpenSSL, this variable could be set to `SSLv3` or `TLSv1.2` to allow all SSLv3 or all `TLSv1.2` ciphers. `TLSv1.3` ciphers can be used, too – see Using TLSv1.3 for details. This system variable implies the ssl option.
- Command line: `--ssl-cipher=name`
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value: None

`ssl_crl`

- Description: Defines a path to a PEM file that should contain one or more revoked X509 certificates to use for TLS. This system variable requires that you use the absolute path, not a relative path.
  - See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information.
  - This variable is only valid if the server was built with OpenSSL. If the server was built with wolfSSL or yaSSL, then this variable is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.
- Command line: `--ssl-crl=name`
- Scope: Global
- Dynamic: No
- Data Type: `file name`
- Default Value: None

`ssl_crlpath`

- Description: Defines a path to a directory that contains one or more PEM files that should each contain one revoked X509 certificate to use for TLS. This system variable requires that you use the absolute path, not a relative path. The directory specified by this variable needs to be run through the openssl rehash command.
  - See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information.
  - This variable is only supported if the server was built with OpenSSL. If the server was built with wolfSSL or yaSSL, then this variable is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.
- Command line: `--ssl-crlpath=name`
- Scope: Global
- Dynamic: No
- Data Type: `directory name`
- Default Value: None

`ssl_key`

- Description: Defines a path to a private key file to use for TLS. This system variable requires that you use the absolute path, not a relative path. This system variable implies the ssl option.
- Command line: `--ssl-key=name`
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value: None

`ssl_passphrase`

- Description: SSL certificate key passphrase. Works similarly to the `--passout/--passin` openssl command-line parameters. The pass phrase value can be formatted as follows:
  - `pass:` *`password`* — Provide the actual *password*.
  - `env:` *`var`* — Obtain the password from the environment variable *var*.
  - `file:` *`filename`* — Read the password from the specified file *filename*. Only the first line, up to the newline character, is read from the stream.

  If `ssl_passphrase` is set, SHOW VARIABLE shows one of `file:`, `env:`, or `pass:`, and doesn't reveal sensitive data.
- Command line: `--ssl-passphrase=val`
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value: None
- Introduced: MariaDB 12.0

`tls_version`

- Description: This system variable accepts a comma-separated list (with no whitespaces) of TLS protocol versions. A TLS protocol version will only be enabled if it is present in this list. All other TLS protocol versions will not be permitted.
  - See Secure Connections Overview: TLS Protocol Versions for more information.
- Command line: `--tls-version=value`
- Scope: Global
- Dynamic: No
- Data Type: `enumerated`
- Default Value:
  - TLSv1.1,TLSv1.2,TLSv1.3 (<= MariaDB 10.6.15, MariaDB 10.11.5, MariaDB 11.0.3)
  - TLSv1.2,TLSv1.3 (>= MariaDB 10.6.16, MariaDB 10.11.6, MariaDB 11.0.4 and later versions)
- Valid Values: TLSv1.0,TLSv1.1,TLSv1.2,TLSv1.3
- Introduced: MariaDB 10.4.6

`version_ssl_library`

- Description: The version of the TLS library that is being used. Note that the version returned by this system variable does not always necessarily correspond to the exact version of the OpenSSL package installed on the

system. OpenSSL shared libraries tend to contain interfaces for multiple versions at once to allow for backward compatibility. Therefore, if the OpenSSL package installed on the system is newer than the OpenSSL version that the MariaDB server binary was built with, then the MariaDB server binary might use one of the interfaces for an older version.
    - See TLS and Cryptography Libraries Used by MariaDB: Checking the Server's OpenSSL Version for more information.

- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value: None

Using TLSv1.3

OpenSSL 1.1.1 introduced support for TLSv1.3. TLSv1.3 is a major rewrite of the TLS protocol. (Some even argued it should've been called TLSv2.0.) Among other things,

- it introduces a new set of cipher suites that only work with TLSv1.3,
- and TLSv1.3 does not support cipher suites from previous TLS protocol versions.

> **Note:**
>
> OpenSSL 1.1.1 is primarily (if not exclusively) supported by Red Hat 8.

This incompatible change had a non-obvious consequence. If you specified particular cipher suites to disable old and obsolete TLS protocol version, you might have inadvertently prevented TLSv1.3 from working, if the TLSv1.3 cipher suites were not added to their cipher list. After upgrading to OpenSSL 1.1.1, this might give the impression that you are using TLSv1.3, when their existing cipher suite configuration might prevent it.

To avoid this problem, OpenSSL developers decided that TLSv1.3 cipher suites should not be affected by the normal cipher-selecting API. This means that the ssl_cipher system variable had no effect on the TLSv1.3 cipher suites. This has been fixed in MariaDB, though – you can use the `ssl_cipher` variable just like before that change.

> **Warning:**
>
> You cannot specify both TLSv1.2 and TLSv1.3 at the same time when MariaDB is built against OpenSSL 1.1.1.

See this OpenSSL blog post and GitHub issue for more information.

Post-Quantum Cryptography in MariaDB TLS

Overview

Quantum computers use quantum mechanics to solve mathematical problems much faster than traditional computers. Their capacity to crack the public-key cryptographic techniques that currently support TLS handshakes, such as RSA and Elliptic Curve Cryptography (ECC), is especially concerning.

This poses a threat known as **harvest now, decrypt later**: an attacker can intercept and store encrypted database communication now, then decrypt it later when sufficiently robust quantum computers are made accessible. Thus, even current threats pose a risk to long-lived sensitive data, such as financial records, intellectual property, and personally identifiable information (PII).

The **National Institute of Standards and Technology** (NIST) in the United States has standardized two post-quantum cryptography algorithms to address this:

- **ML-KEM** (Module Lattice Key Encapsulation Mechanism) (FIPS 203): A key encapsulation technique for quantum-resistant key exchange during TLS handshakes.
- **ML-DSA** (Module Lattice Digital Signature Algorithm) (FIPS 204): A digital signature scheme for quantum-resistant server authentication.
- **Hybrid mode**: Use of both classical and post-quantum algorithms together during the transition period. The session key is secure if either algorithm remains unbroken.

MariaDB automatically negotiates ML-KEM for TLS 1.3 key exchange when linked against **OpenSSL 3.5 or later**, requiring no further configuration. Because of this, MariaDB connections are inherently quantum-resistant in transit.

Requirements

Component	Version Requirement
MariaDB Server	10.8.1 (source), backported to 10.5.17 (source) as well as to 10.6.9 and 10.7.5 (source). (regarding the sources: MariaDB support for OpenSSL 3.0 guarantees support for 3.5.0 and later too due to API and ABI compatibility)
OpenSSL	3.5.0 or later

How It Works

MariaDB assigns the system OpenSSL library to handle TLS operations. As a TLS 1.3 key exchange group, OpenSSL 3.5 included native support for ML-KEM. A MariaDB server will automatically publish ML-KEM key exchange groups during the TLS 1.3 handshake if OpenSSL 3.5 or later is installed.

There is no need to modify any server system variables. During this time of transition, **hybrid mode** is used. This indicates that ML-KEM and a traditional method like classical Elliptic Curve (X25519) are used for key exchange. This hybrid classical and post-quantum approach is reflected in the negotiated group that can be seen in the handshake output: `X25519MLKEM768`.

This ensures backward compatibility. Clients that do not support ML-KEM continue to use traditional key exchange to establish connections.

Verifying Quantum-Resistant TLS

By connecting to the OpenSSL client and examining the negotiated TLS group, you can verify that a MariaDB connection uses ML-KEM.

```
$ openssl s_client -starttls mysql localhost:3306
```

Output

Look for the Negotiated TLS1.3 group in the output:

```
Peer signing digest: SHA256
Peer signature type: rsa_pss_rsae_sha256
Negotiated TLS1.3 group: X25519MLKEM768
```

A value of `X25519MLKEM768` indicates that the hybrid classical and ML-KEM key exchange is operational. During transit, the connection is quantum-resistant.

Compatibility

MariaDB automatically returns to traditional TLS 1.3 key exchange when a connecting client does not support post-quantum key exchange groups. Current clients and applications do not require any setup adjustments. Connections that are limited to classical methods remain unchanged.

Data-in-Transit and Data-at-Rest

Post quantum cryptography secures data while it is transmitted across a network. Data at rest should also be protected with quantum-resistant encryption to ensure comprehensive quantum resistance. For this reason, AES-256 is advised since it offers enough key length to survive known quantum attacks. See Data-at-Rest-Encryption for information on how to enable encryption for table data and tablespaces in MariaDB.

Performance Considerations

- **Handshake size**: Post-quantum algorithms may produce slightly larger handshakes.
- **Performance impact**: Session reuse reduces overhead.
- **Workload suitability**: Appropriate for typical database workloads.

This page is licensed: CC BY-SA / Gnu FDL

Data-at-Rest Encryption (TDE) Fundamentals

MariaDB Data-at-Rest Encryption, also known as Transparent Data Encryption (TDE), protects your data by encrypting files directly on the storage media. This ensures that if physical disks or backup files are stolen, the data remains unreadable without the corresponding encryption keys.

Security Context

When Encryption Protects Your Data

- Physical Theft: Unauthorized access to hard drives or storage arrays.
- Backup Exposure: If database backups are intercepted or accessed by unauthorized parties.
- Service Provider Access: Preventing infrastructure administrators in cloud or managed environments from viewing sensitive data.

When Encryption is No Help

- Authorized Access: Users with valid SQL credentials will still see decrypted data; TDE does not replace a robust User Account Management strategy.
- Application Vulnerabilities: TDE does not prevent SQL injection or application-level data breaches.
- Data-in-Transit: This feature only secures stored data. Use TLS/SSL to secure data moving across the network.

Architecture and Lifecycle

MariaDB performs encryption at the I/O layer. This process is “transparent” because applications and queries do not need to be modified to interact with encrypted data.

Once a Key Management plugin is configured, encryption occurs automatically whenever MariaDB writes pages to disk, and decryption occurs when data is read back into memory.

- Write Path: When MariaDB flushes data from the buffer pool to the disk, the data is encrypted.
- Read Path: When MariaDB reads data from the disk into memory, it is decrypted.
- Memory: Data stored in RAM (such as the buffer pool) remains in a decrypted state while in use.

Storage Engine Support

MariaDB provides flexible control over what is encrypted, though support and requirements vary by component:

- InnoDB: Fully supported. You can encrypt all tablespaces, individual tables, and the InnoDB redo log. For details, see InnoDB Encryption.
- Aria: Supported only for tables created with `ROW_FORMAT=PAGE` (the default). For details, see Aria Encryption.
- Binary Logs: MariaDB can encrypt binary logs and relay logs to protect the replication pipeline. See Managing Binary Log Encryption.
- Temporary Files: Internal on-disk temporary files can be encrypted by setting `encrypt_tmp_files=ON`.

> **Note:**
>
> **Enterprise Server** provides encryption for **Galera Cluster** via GCache.
> How GCache encryption is enabled and disabled is detailed on this page.

Limitations

The following elements are not encrypted by the MariaDB server:

- Metadata: Information in `.frm` files and the system data dictionary.
- Specific Logs: The MariaDB Error Log, General Query Log, and Slow Query Log.
- Aria Control Log: While Aria tables can be encrypted, the Aria storage engine log is not currently encrypted.
- Utilities: Tools like `mariadb-binlog` require the `--read-from-remote-server` flag to read encrypted content.

Key Management

Encryption requires a key management and encryption plugin. These plugins are responsible for managing the 32-bit integer key identifiers and performing the cryptographic operations. You must install and configure a Key Management Plugin before enabling encryption options for storage engines.

> **Note:**
>
> For the rest of this page, we assume you're using the File Key Management Encryption Plugin. If you're using a different one, adjust the configuration and SQL statements accordingly.

Enabling Data-at-Rest Encryption

Enabling data-at-rest encryption encompasses these steps:

1. Creating a key file.
2. Installing and enabling a key management plugin.
3. Enabling encryption for Aria tables, InnoDB tables, or both.
4. Verifying encryption is turned on.

> **Note:**
>
> The path used in these instructions (`/etc/mysql/encryption/`) is common for most Linux systems. Adjust if your operating system uses a different path.

> **Note:**
>
> MariaDB server must be restarted several times. On most Linux systems, the command for that is `sudo systemctl restart mariadb` . Consult your operating system documentation to find out what your system uses.
>
> If you're getting errors, particularly if MariaDB fails to start, for example due to a configuration issue, inspect the error log. On many modern Linux versions, this can be done using `journalctl` . Example:
>
> ```
> sudo journalctl -u mariadb -n 1000 --no-pager | grep ERROR
> ```

Step 1

Create the key file.

In this step, we create a key file that fulfills basic requirements. It contains only one unencrypted key, which is good enough to perform the rest of the steps. It is highly recommended, though, to use multiple keys, and to encrypt the key files. See Creating the Key File.

CURRENT ENTERPRISE SERVER

Run these commands to create an `encryption` folder, and a 32 byte (256 bit) long key file within that folder.

```
mkdir -p /etc/mysql/encryption
echo $(echo -n "1;1;" ; openssl rand -hex 32) | sudo tee -a /etc/mysql/encryption/keyfile.txt
```

ENTERPRISE SERVER < 11.8 & COMMUNITY SERVER

Run these commands to create an `encryption` folder, and a 32 byte (256 bit) long key file within that folder.

```
mkdir -p /etc/mysql/encryption
echo $(echo -n "1;" ; openssl rand -hex 32) | sudo tee -a /etc/mysql/encryption/keyfile.txt
```

Step 2

Install and enable a key management plugin.

Add the following to your configuration file (for instance, `my.cnf`), then restart the server so the changes take effect:

```
[mariadb]
plugin_load_add = file_key_management
file_key_management_filename = /etc/mysql/encryption/keyfile.txt
# The following line is optional but highly recommended.
# Uncomment it to enable usage of an encrypted key file.
# file_key_management_filekey = FILE:/etc/mysql/encryption/keyfile.key
file_key_management_encryption_algorithm = AES_CTR
```

For details about file name, file key, and encryption algorithm, see File Key Management Encryption Plugin.

Step 3

Enable encryption.

You can encrypt a number of database objects by setting the respective variables:

- InnoDB user tables – innodb_encrypt_tables
- InnoDB redo log – innodb_encrypt_log
- InnoDB temporary files – innodb_encrypt_temporary_tables
  MariaDB creates temporary files on disk, for instance, files used for file sorts. It is recommended to encrypt those, too.
- Aria user tables – aria_encrypt_tables
- Aria temporary tables – encrypt_tmp_disk_tables

To configure global encryption for all of those objects, add this to your configuration file (for instance, `my.cnf`), then restart the server:

```
[mariadb]
innodb_encrypt_tables = ON
innodb_encrypt_log = ON
innodb_encrypt_temporary_tables = ON
aria_encrypt_tables = ON
encrypt_tmp_disk_tables = ON
```

Alternatively, set it by running the following statements. Remember, though, that the settings do not persist across server restarts. Also note that some of the variables cannot be set at runtime – they have to be set in a configuration file:

```
SET GLOBAL innodb_encrypt_tables = ON;   -- for InnoDB tables
SET GLOBAL aria_encrypt_tables = ON;     -- for Aria tables
SET GLOBAL encrypt_tmp_disk_tables = ON; -- for Aria temporary tables
```

> **Note:**
>
> Particularly InnoDB has more encryption options. You can fine-tune the encryption, for instance, configure encryption threads. Those details are covered on this page.

Step 4

Verify encryption is turned on.

Make sure that the global encryption you configured is turned on, by issuing this statement:

```
SELECT
 'InnoDB Tables' AS Component, @@innodb_encrypt_tables AS Active
 UNION SELECT 'InnoDB Logs', @@innodb_encrypt_log
 UNION SELECT 'InnoDB Temp', @@innodb_encrypt_temporary_tables
 UNION SELECT 'Aria System', @@aria_encrypt_tables
 UNION SELECT 'Aria Temp', @@encrypt_tmp_disk_tables;
```

If encryption of all database objects is successfully enabled, this is the output of the query:

```
+---------------+--------+
| Component     | Active |
+---------------+--------+
| InnoDB Tables | ON     |
| InnoDB Logs   | 1      |
| InnoDB Temp   | 1      |
| Aria System   | 1      |
| Aria Temp     | 1      |
+---------------+--------+
```

Disabling Data-at-Rest Encryption

If you determine that encryption is no longer necessary, you can revert the system to an unencrypted state.

Prerequisites

- Encryption Status: MariaDB Enterprise Server must currently have data-at-rest encryption enabled and active.
- Key Management Access: You must have the original key management plugin active and the correct keys loaded to facilitate the decryption of the data.
- Sufficient Disk Space: Ensure adequate free space is available to accommodate the rewritten, unencrypted data files.

Step 1

Decrypt tables.

Disable global encryption at the storage engine level by issuing these statements. Note that some variables cannot be turned off at runtime – they have to be removed from the server configuration (for instance, `my.cnf`), and require a server restart:

```
SET GLOBAL innodb_encrypt_tables = OFF;   -- InnoDB tables
SET GLOBAL aria_encrypt_tables = OFF;     -- Aria tables
SET GLOBAL encrypt_tmp_disk_tables = OFF; -- Aria temporary tables
```

> **Note:**
>
> Any per-table encryption for InnoDB tables explicitly created with `ENCRYPTED=YES` must be manually decrypted using `ALTER TABLE table_name ENCRYPTED=NO`.

Step 2

Disable log and temp encryption.

Update your configuration file (`my.cnf`) to stop encrypting Aria and InnoDB tables, as well as new logs and temporary files:

```
[mariadb]
innodb_encrypt_tables = OFF
innodb_encrypt_log = OFF
innodb_encrypt_temporary_tables = OFF
aria_encrypt_tables = OFF
encrypt_tmp_disk_tables = OFF
```

Step 3

Monitor decryption progress.

You must wait for the background threads to finish decrypting data pages before removing the keys. Monitor the status for InnoDB tables via the Information Schema (there's no built-in way to monitor the status for Aria tables):

```
SELECT NAME, ENCRYPTION_SCHEME, ROTATING_OR_FLUSHING
FROM INFORMATION_SCHEMA.INNODB_TABLESPACES_ENCRYPTION
WHERE ENCRYPTION_SCHEME != 0;
```

> **Warning:**
>
> A restore from an encrypted backup isn't possible after removing the keys.

Step 4

Remove the key management plugin.

Only after all tables and logs are confirmed as unencrypted should you uninstall the encryption plugin and remove its configuration from your `my.cnf` file. For instance, if you're using the File Key Management Encryption Plugin, uninstall it:

```
UNINSTALL SONAME 'file_key_management';
```

Remove its configuration, then restart the server:

```
[mariadb]
# Remove or comment out the following line
plugin_load_add = file_key_management
```

Step 5

Verify encryption is turned off.

Use the same SQL statement shown above to verify encryption is turned off.

TDE in Action: Real-World Behavior

Transparent Data Encryption (TDE) is designed to protect data "at rest" while remaining completely invisible to standard SQL operations. With encryption turned on, MariaDB applies encryption to all new tables automatically.

Automatic Encryption (InnoDB & Aria)

For the subsequent instructions, we use these tables. With encryption turned on, note that they're encrypted without using any special syntax:

```
-- Create an InnoDB table
CREATE TABLE sensitive_accounts_innodb (
    id INT PRIMARY KEY,
    account_name VARCHAR(100)
) ENGINE=InnoDB;

-- Create an Aria table
-- Note that the ROW_FORMAT must be PAGE; otherwise, encryption isn't possible
CREATE TABLE sensitive_accounts_aria (
    id INT PRIMARY KEY,
    account_name VARCHAR(100)
) ENGINE=Aria ROW_FORMAT=PAGE;
```

Verifying Encryption Status

Because InnoDB and Aria handle data differently, you use two different methods to verify their encryption status.

For InnoDB

Check the `information_schema` to see the tablespace encryption scheme. If it's set to `1`, the table is encrypted.

```
SELECT NAME, ENCRYPTION_SCHEME
FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
WHERE NAME LIKE '%sensitive_accounts_innodb%';
```

```
+--------------------------------+-------------------+
| NAME                           | ENCRYPTION_SCHEME |
+--------------------------------+-------------------+
| test/sensitive_accounts_innodb |                 1 |
+--------------------------------+-------------------+
```

For Aria

There's no built-in way to check the encryption status of Aria tables, but you can check the contents of their `.MAD` files (the Aria data files) with commands like `cat`:

```
sudo cat /var/lib/mysql/test/sensitive_accounts_aria.MAD | more
```

If you see unintelligible output rather than something resembling data, the Aria table is encrypted.

Transparent Data Access

Whether the table is InnoDB or Aria, the encryption is **transparent**. Standard SQL statements work without modification, as the engine decrypts the data in memory (the Buffer Pool for InnoDB or Page Cache for Aria).

```
-- Standard inserts work for both
INSERT INTO sensitive_accounts_innodb VALUES (1, 'Customer InnoDB');
INSERT INTO sensitive_accounts_aria VALUES (1, 'Customer Aria');

-- Standard selects return plain text
SELECT * FROM sensitive_accounts_innodb;
SELECT * FROM sensitive_accounts_aria;
```

Manual Control: Disabling Encryption

If you need to exempt a specific table from the global encryption policy, use the `ENCRYPTED` attribute.

> **Note:**
>
> This is only possible for InnoDB tables.

Decrypting the Tables

Decrypting tables is done with an `ALTER TABLE` statement. For InnoDB tables, you can do this while global InnoDB table encryption is turned on.

> **Note:**
>
> For Aria tables, you can only do this when global Aria table encryption is turned off.

```
-- Disable encryption for the InnoDB table
ALTER TABLE sensitive_accounts_innodb ENCRYPTED=NO;
SELECT NAME, ENCRYPTION_SCHEME  FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
       WHERE NAME LIKE '%sensitive_accounts_innodb%';
+--------------------------------+-------------------+
| NAME                           | ENCRYPTION_SCHEME |
+--------------------------------+-------------------+
| test/sensitive_accounts_innodb |                 0 |
+--------------------------------+-------------------+

-- Disable encryption for the Aria table
-- This is only possible after disabling global Aria encryption
ALTER TABLE sensitive_accounts_aria ENGINE=Aria, ALGORITHM=COPY;
```

Reencrypting the Tables

```
ALTER TABLE sensitive_accounts_innodb ENCRYPTED=YES;
SELECT NAME, ENCRYPTION_SCHEME  FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
       WHERE NAME LIKE '%sensitive_accounts_innodb%';
+--------------------------------+-------------------+
| NAME                           | ENCRYPTION_SCHEME |
+--------------------------------+-------------------+
| test/sensitive_accounts_innodb |                 1 |
+--------------------------------+-------------------+
```

Managing Binary Log Encryption

MariaDB can encrypt binary logs and relay logs to ensure that data modifications stored on disk are only accessible through the database server.

Prerequisites

Binary log and relay log encryption requires a configured Key Management and Encryption Plugin (such as File Key Management or AWS KMS). MariaDB specifically uses encryption key ID 1 for binary logs.

Key management plugin encryption looks like this (depending on the plugin used, and on the operating system the plugin is installed on):

```
[mariadb]
# File Key Management
plugin_load_add = file_key_management
file_key_management_filename = /etc/mysql/encryption/keyfile.enc
file_key_management_filekey = FILE:/etc/mysql/encryption/keyfile.key
file_key_management_encryption_algorithm = AES_CTR
```

Enabling Encryption

Binary log encryption is controlled by the `encrypt_binlog` system variable.

> **Step 1**
>
> **Stop the MariaDB server.**

> **Step 2**
>
> **Edit the configuration file.**
>
> Add the following to your configuration file (e.g., `my.cnf`):
>
> ```
> [mariadb]
> encrypt_binlog = ON
> ```

> **Step 3**
>
> **Start the server.**

From this point forward, all new binary logs are encrypted. To remove old, unencrypted logs, use `RESET MASTER` or `PURGE BINARY LOGS`.

Key Rotation

If your key management plugin supports rotation (check here), the server can use new key versions for new binary logs. However, unlike InnoDB, binary logs do not have a background re-encryption mechanism. Existing binary log files remain encrypted with the key version used at the time of their creation.

Reading Encrypted Binary Logs

Because encrypted logs cannot be read directly by standard text editors, you must use the `mariadb-binlog` utility.

Method 1: Remote Decryption (Recommended)

The most secure method is to have the server stream the decrypted events. This avoids the need to distribute encryption keys to administrative workstations.

```
mariadb-binlog --read-from-remote-server --user=root -p binlog.000012 > decrypted.sql
```

Method 2: Local Decryption

You can decrypt logs locally if the `mariadb-binlog` utility has access to the same key management plugin and key material used by the server.

```
mariadb-binlog /var/lib/mysql/binlog.000012 > decrypted.sql
```

Disabling Encryption

Disabling encryption stops the server from encrypting future logs. It does not decrypt existing files.

> **Step 1**
>
> **Stop the MariaDB server.**

> **Step 2**
>
> **Edit the configuration file.**
>
> Add the following to your configuration file (e.g., `my.cnf`):
>
> ```
> [mariadb]
> encrypt_binlog = OFF
> ```

> **Step 3**
>
> **Start the server.**

> **Warning:**
>
> Important: Keep your key management plugin loaded as long as you have encrypted binary logs on disk that you may need to read. If the plugin is removed, the server and `mariadb-binlog` will be unable to decrypt those older files.

Understanding Binlog Encryption

Behind the Scenes

When starting with binary log encryption, MariaDB Server logs a `Format_descriptor_log_event` and a `START_ENCRYPTION_EVENT`, then encrypts all subsequent events for the binary log.

Each event header and footer are created and processed to produce encrypted blocks. These encrypted blocks are produced before transactions are committed and before the events are flushed to the binary log. As such, they exist in an encrypted state in memory buffers and in the `IO_CACHE` files for user connections.

Effects of Data-at-Rest Encryption on Replication

When using encrypted binary logs with replication, you can have different encryption keys on the master and the replica. The master decrypts encrypted binary log events as it reads them from disk, and before its binary log dump thread sends them to the replica, so the replica actually receives the unencrypted binary log events.

To ensure that binary log events are encrypted as they are transmitted between the master and replica, use TLS with the replication connection.

Effects of Data-at-Rest Encryption on mariadb-binlog

mariadb-binlog does not have the ability to decrypt encrypted binary logs on its own (see MDEV-8813). In order to use `mariadb-binlog` with encrypted binary logs, use the –read-from-remote-server command-line option, so that the server can decrypt the binary logs for `mariadb-binlog`.

Aria Encryption

See Aria: Encryption Overview.

Introduction to encrypting Aria tables, covering the necessary system variables (aria_encrypt_tables, encrypt_tmp_disk_tables) and how to verify encryption status by inspecting data files.

See Aria: Enabling Encryption.

Step-by-step guide to enabling encryption for user-created and internal temporary Aria tables, including the requirement to manually rebuild existing tables using ALTER TABLE.

See Aria: Encryption Keys.

Details how Aria manages encryption keys (using ID 1 for user tables and ID 2 for temporary tables) and notes limitations regarding key rotation and per-table key assignment.

See Aria: Disabling Encryption.

Instructions for safely disabling encryption on Aria tables, emphasizing the need to rebuild tables to an unencrypted state before removing key management plugins.

This page is licensed: CC BY-SA / Gnu FDL

Aria: Encryption Overview

MariaDB can encrypt data in tables that use the Aria storage engine. This includes both user-created tables and internal on-disk temporary tables that use the Aria storage engine. This ensures that your Aria data is only accessible through MariaDB.

For encryption with the InnoDB and XtraDB storage engines, see Encrypting Data for InnoDB/XtraDB.

Basic Configuration

In order to enable encryption for tables using the Aria storage engine, there are a couple server system variables that you need to set and configure. Most users will want to set aria_encrypt_tables and encrypt_tmp_disk_tables.

Users of data-at-rest encryption will also need to have a key management and encryption plugin configured. Some examples are File Key Management Plugin and AWS Key Management Plugin.

```
[mariadb]
# File Key Management
plugin_load_add = file_key_management
file_key_management_filename = /etc/mysql/encryption/keyfile.enc
file_key_management_filekey = FILE:/etc/mysql/encryption/keyfile.key
file_key_management_encryption_algorithm = AES_CTR

# Aria Encryption
aria_encrypt_tables=ON
encrypt_tmp_disk_tables=ON
```

Determining Whether a Table is Encrypted

The InnoDB storage engine has the information_schema.INNODB_TABLESPACES_ENCRYPTION table that can be used to get information about which tables are encrypted. Aria does not currently have anything like that (see MDEV-17324 about that).

To determine whether an Aria table is encrypted, you currently have to search the data file for some plain text that you know is in the data.

For example, let's say that we have the following table:

```
SELECT * FROM db1.aria_tab LIMIT 1;
+----+------+
| id | str  |
+----+------+
|  1 | str1 |
+----+------+
1 row IN SET (0.00 sec
```

Then, we could search the data file that belongs to `db1.aria_tab` for `str1` using a command-line tool, such as strings:

```
$ sudo strings /var/lib/mysql/db1/aria_tab.MAD | grep "str1"
str1
```

If you can find the plain text of the string, then you know that the table is not encrypted.

Encryption and the Aria Log

Only Aria tables are currently encrypted. The Aria log is not yet encrypted. See MDEV-8587.

This page is licensed: CC BY-SA / Gnu FDL

Aria: Enabling Encryption

To enable data-at-rest encryption for tables using the Aria storage engine, configure the server to use an Encryption Key Management plugin. Once this is done, you can enable encryption by setting the relevant system variables.

Encrypting User-Created Tables

For user-created tables, enable encryption by setting the aria_encrypt_tables system variable to `ON`, then restart the server:

```
[mariadb]
aria_encrypt_tables = ON
```

Alternatively, set the variable with an SQL statement. This doesn't require a server restart, but the setting is lost on server restart:

```
SET GLOBAL aria_encrypt_tables=ON
```

Once this is set, Aria enables encryption on all newly created tables.

> **Note:**
>
> **Encryption only works if the ROW_FORMAT table option set to `PAGE`.**
>
> Aria does not support encryption of tables where the `ROW_FORMAT` table option is set to `FIXED` or `DYNAMIC`.

> **Note:**
>
> Aria does not support the ENCRYPTED table option (see MDEV-18049 about that).

> **Note:**
>
> Encryption for Aria can only be enabled globally using the aria_encrypt_tables system variable.

Encrypting Existing Tables

In cases where you have existing Aria tables that you would like to encrypt, the process is a little more complicated. Unlike InnoDB, Aria does not utilize background encryption threads to automatically perform encryption changes (see MDEV-18971 about that). Therefore, to encrypt existing tables, you need to identify each table that needs to be encrypted, and then you need to manually rebuild each table.

First, set the `aria_encrypt_tables` system variable to encrypt new tables.

```
SET GLOBAL aria_encrypt_tables=ON
```

Identify Aria tables that have the `ROW_FORMAT` table option set to `PAGE`.

```
SELECT TABLE_SCHEMA, TABLE_NAME
FROM information_schema.TABLES
WHERE ENGINE='Aria'
  AND ROW_FORMAT='PAGE'
  AND TABLE_SCHEMA != 'information_schema';
```

For each table in the result set, issue an `ALTER TABLE` statement to rebuild the table.

```
ALTER TABLE aria_table ENGINE=Aria ROW_FORMAT=PAGE;
```

This statement causes Aria to rebuild the table using the `ROW_FORMAT` table option. Since you enabled encryption, Aria also encrypts the table in the process.

Encrypting Internal Temporary Tables on Disk

During the execution of queries, MariaDB routinely creates internal temporary tables. These internal temporary tables initially use the MEMORY storage engine, which is entirely stored in memory. When the table size exceeds the allocation defined by the max_heap_table_size system variable, MariaDB writes the data to disk using another storage engine. If you have the aria_used_for_temp_tables set to `ON`, MariaDB uses Aria in writing the internal temporary tables to disk.

Encryption for internal temporary tables is handled separately from encryption for user-created tables. To enable encryption for these tables, set the encrypt_tmp_disk_tables system variable to `ON`. Once set, all internal temporary tables that are written to disk using Aria are automatically encrypted.

Manually Encrypting Tables

Currently, Aria does not support manually encrypting tables through the ENCRYPTED and ENCRYPTION_KEY_ID table options. For more information, see MDEV-18049.

In cases where you want to encrypt tables manually or set the specific encryption key, use InnoDB.

This page is licensed: CC BY-SA / Gnu FDL

Aria: Encryption Keys

As with other storage engines that support data-at-rest encryption, Aria relies on an Encryption Key Management plugin to handle its encryption keys. Where the support is available, Aria can use multiple keys.

Encryption Keys

MariaDB keeps track of each encryption key internally using a 32-bit integer, which serves as the key identifier. Unlike InnoDB, Aria does not support the ENCRYPTION_KEY_ID table option (for more information, see MDEV-18049), which allows the user to specify the encryption key to use. Instead, Aria defaults to specific encryption keys provided by the Encryption Key Management plugin.

- When working with user-created tables, Aria encrypts them to disk using the ID 1 key.
- When working with internal temporary tables written to disk, Aria encrypts them to disk using the ID 2 key, unless there is no ID 2 key, then it falls back on the ID 1 key.

Key Rotation

Some key management and encryption plugins allow you to automatically rotate and version your encryption keys. If a plugin support key rotation, and if it rotates the encryption keys, then InnoDB's background encryption threads can re-encrypt InnoDB pages that use the old key version with the new key version. However, Aria does **not** have a similar mechanism, which means that the tables remain encrypted with the older key version. For more information, see MDEV-18971.

In order for key rotation to work, both the backend key management service (KMS) and the corresponding key management and encryption plugin have to support key rotation. See Encryption Key Management: Support for Key Rotation in Encryption Plugins to determine which plugins currently support key rotation.

This page is licensed: CC BY-SA / Gnu FDL

Aria: Disabling Encryption

Overview

This guide provides instructions for safely disabling encryption for the Aria storage engine, including user-created tables and internal on-disk temporary tables.

To fully disable encryption, you must set the relevant system variables and then rebuild each table to an unencrypted state.

> **Warning:**
>
> **Important Safety Precautions**
>
> - Do not remove your Encryption Key Management plugin yet. MariaDB must be able to read the existing encrypted data to rewrite it in an unencrypted state.
> - Maintain configurations. Keep your key management settings in place until the very last step of the process.

Step 1

Disable encryption for new data.

First, prevent MariaDB from encrypting any new data by updating the global system variables.

User-Created Tables

Set `aria_encrypt_tables` to `OFF`. This ensures that any new Aria tables created or existing tables rebuilt from this point forward will be unencrypted.

```
SET GLOBAL aria_encrypt_tables = OFF;
```

To make this change persistent across server restarts, add the following to your MariaDB configuration file (for instance, `my.cnf`):

```
[mysqld]
aria_encrypt_tables = OFF
```

Internal On-Disk Temporary Tables

MariaDB creates internal temporary tables using the Aria engine when `aria_used_for_temp_tables` is set to `ON`. To ensure these are no longer encrypted, set:

```
SET GLOBAL encrypt_tmp_disk_tables = OFF;
```

Step 2

Identify encrypted Aria tables.

Aria does not use background encryption threads (unlike InnoDB). Therefore, tables already on disk will remain encrypted until you manually rebuild them.

Run the following query to identify which tables need to be rebuilt:

```
SELECT TABLE_SCHEMA, TABLE_NAME
FROM information_schema.TABLES
WHERE ENGINE = 'Aria'
  AND ROW_FORMAT = 'PAGE'
  AND TABLE_SCHEMA NOT IN ('information_schema', 'performance_schema', 'sys')
  AND (CREATE_OPTIONS LIKE '%`encrypted`=yes%' OR CREATE_OPTIONS LIKE '%`encrypted`=1%');
```

> **Step 3**
>
> **Rebuild tables to decrypt.**
>
> To decrypt the tables identified in the previous step, you must rebuild them using an `ALTER TABLE` statement. This causes MariaDB to rewrite the data (`.MAD`) and index (`.MAI`) files in an unencrypted format.
>
> **Option A: Manual Rebuild (Single Table)**
>
> Use the following statement to rebuild a specific table:
>
> ```
> ALTER TABLE db_name.table_name ENGINE=Aria, ALGORITHM=COPY;
> ```
>
> **Option B: Generate Rebuild Statements (Bulk)**
>
> You can generate the DDL for all encrypted Aria tables at once using this query:
>
> ```
> SELECT CONCAT('ALTER TABLE `', table_schema, '`.`', table_name,
>              '` ENGINE=Aria, ALGORITHM=COPY;') AS ddl
> FROM information_schema.tables
> WHERE ENGINE='Aria'
>   AND TABLE_SCHEMA NOT IN ('mysql','information_schema','performance_schema','sys')
>   AND (CREATE_OPTIONS LIKE '%`encrypted`=yes%' OR CREATE_OPTIONS LIKE '%`encrypted`=1%');
> ```

> **Step 4**
>
> **Verify and clean up.**
>
> - Verify: Run the query from Step 2 again to ensure no encrypted Aria tables remain.
> - Remove Plugins (optional): Once all Aria tables (and any InnoDB tables or binary logs) are decrypted, you can safely remove the Encryption Key Management plugin from your configuration file and restart the server.

InnoDB: Encryption Overview

MariaDB supports data-at-rest encryption for tables using the InnoDB storage engines. When enabled, the server encrypts data when it writes it to and decrypts data when it reads it from the file system. You can configure InnoDB encryption to automatically have all new InnoDB tables automatically encrypted, or specify encrypt per table.

For encrypting data with the Aria storage engine, see Encrypting Data for Aria.

InnoDB Encryption and Decryption Behavior

When data-at-rest encryption is enabled for InnoDB, encryption and decryption occur at specific points during disk I/O operations.

When is InnoDB data encrypted?

When InnoDB pages are written to disk, they are automatically encrypted.

When is InnoDB data decrypted?

InnoDB pages are decrypted before they are read from disk and stored in the InnoDB buffer pool. A page remains decrypted in memory while it is in the buffer pool. As a result, decrypted memory pages may include data from rows, columns, or even tables that the current query does not directly access.

Basic Configuration

Using data-at-rest encryption requires that you first configure an Encryption Key Management plugin, such as the file_key_management or aws_key_management plugins.
MariaDB uses this plugin to store, retrieve and manage the various keys it uses when encrypting data to and decrypting data from the file system.

Once you have the plugin configured, you need to set a few additional system variables to enable encryption on InnoDB tables, including innodb_encrypt_tables, innodb_encrypt_log, innodb_encryption_threads, innodb_encrypt_temporary_tables and innodb_encryption_rotate_key_age.

```
[mariadb]
...

# File Key Management
plugin_load_add = file_key_management
file_key_management_filename = /etc/mysql/encryption/keyfile.enc
file_key_management_filekey = FILE:/etc/mysql/encryption/keyfile.key
file_key_management_encryption_algorithm = AES_CTR

# InnoDB Encryption
innodb_encrypt_tables = ON
innodb_encrypt_temporary_tables = ON
innodb_encrypt_log = ON
innodb_encryption_threads = 4
innodb_encryption_rotate_key_age = 1
```

For more information on system variables for encryption and other features, see the InnoDB system variables page.

Creating Encrypted Tables

To create encrypted tables, specify the table options `ENCRYPTED=YES` and `ENCRYPTION_KEY_ID=` with a corresponding key id;

```
CREATE TABLE t (i INT PRIMARY KEY) ENGINE=InnoDB ENCRYPTED=YES ENCRYPTION_KEY_ID=2;
```

Finding Encrypted Tables

When using data-at-rest encryption with the InnoDB storage engine, it is not necessary that you encrypt every table in your database. You can check which tables are encrypted and which are not by querying the INNODB_TABLESPACES_ENCRYPTION table in the Information Schema. This table provides information on which tablespaces are encrypted, which encryption key each tablespace is encrypted with, and whether the background encryption threads are currently working on the tablespace. Since the system tablespace can also contain tables, it can be helpful to join the `INNODB_TABLESPACES_ENCRYPTION` table with the INNODB_SYS_TABLES table to find out the encryption status of each specific table, rather than each tablespace. For example:

```
SELECT st.SPACE, st.NAME, te.ENCRYPTION_SCHEME, te.ROTATING_OR_FLUSHING
FROM information_schema.INNODB_TABLESPACES_ENCRYPTION te
JOIN information_schema.INNODB_SYS_TABLES st
   ON te.SPACE = st.SPACE \G

Redo Logs

Using data-at-rest encryption with InnoDB, the innodb_encrypt_tables system variable only encrypts the InnoDB tablespaces. In order to also encrypt the InnoDB Redo Logs, you also need to set the innodb_encrypt_log system variable.

Where the encryption key management plugin supports key rotation, the InnoDB Redo Log can also rotate encryption keys. In previous releases, the Redo Log can only use the first encryption key.

InnoDB: Enabling Encryption

In order to enable data-at-rest encryption for tables using the InnoDB storage engines, you first need to configure the server to use an Encryption Key Management plugin. Once this is done, you can enable encryption by setting the innodb_encrypt_tables system variable to encrypt the InnoDB system and file tablespaces and setting the innodb_encrypt_log system variable to encrypt the InnoDB Redo Log.

Setting these system variables enables the encryption feature for InnoDB tables on your server. To use the feature, you need to use the ENCRYPTION_KEY_ID table option to set what encryption key you want to use and set the ENCRYPTED table option to enable encryption.

When encrypting any InnoDB tables, the best practice is also enable encryption for the Redo Log. If you have encrypted InnoDB tables and have not encrypted the Redo Log, data written to an encrypted table may be found unencrypted in the Redo Log.

Enabling Encryption for Automatically Encrypted Tablespaces

The innodb_encrypt_tables system variable controls the configuration of automatic encryption of InnoDB tables. It has the following possible values:

Option	Description
OFF	Disables table encryption.
ON	Enables table encryption, but allows unencrypted tables to be created.
FORCE	Enables table encryption, and doesn't allow unencrypted tables to be created.

When innodb_encrypt_tables is set to `ON`, InnoDB tables are automatically encrypted by default. For example, the following statements create an encrypted table and confirm that it is encrypted:

```
SET GLOBAL innodb_encryption_threads=4;

SET GLOBAL innodb_encrypt_tables=ON;

SET SESSION innodb_default_encryption_key_id=100;

CREATE TABLE tab1 (
   id INT PRIMARY KEY,
   str VARCHAR(50)
);

SELECT NAME, ENCRYPTION_SCHEME, CURRENT_KEY_ID
FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
WHERE NAME='db1/tab1';
+----------+-------------------+----------------+
| NAME     | ENCRYPTION_SCHEME | CURRENT_KEY_ID |
+----------+-------------------+----------------+
| db1/tab1 |                 1 |            100 |
+----------+-------------------+----------------+
```

When innodb_encrypt_tables is set to `ON`, an unencrypted InnoDB table can be created by setting the ENCRYPTED table option to `NO` for the table. For example, the following statements create an unencrypted table and confirm that it is not encrypted:

```
SET GLOBAL innodb_encryption_threads=4;

SET GLOBAL innodb_encrypt_tables=ON;

SET SESSION innodb_default_encryption_key_id=100;

CREATE TABLE tab1 (
   id INT PRIMARY KEY,
   str VARCHAR(50)
) ENCRYPTED=NO;

SELECT NAME, ENCRYPTION_SCHEME, CURRENT_KEY_ID
FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
WHERE NAME='db1/tab1';
+----------+-------------------+----------------+
| NAME     | ENCRYPTION_SCHEME | CURRENT_KEY_ID |
+----------+-------------------+----------------+
| db1/tab1 |                 0 |            100 |
+----------+-------------------+----------------+
```

When innodb_encrypt_tables is set to `FORCE`, InnoDB tables are automatically encrypted by default, and unencrypted InnoDB tables can **not** be created. In this scenario, if you set the ENCRYPTED table option to `NO` for a table, then you will encounter an error. For example:

```
SET GLOBAL innodb_encryption_threads=4;

SET GLOBAL innodb_encrypt_tables='FORCE';

SET SESSION innodb_default_encryption_key_id=100;

CREATE TABLE tab1 (
   id INT PRIMARY KEY,
   str VARCHAR(50)
) ENCRYPTED=NO;
ERROR 1005 (HY000): Can't create table `db1`.`tab1` (errno: 140 "Wrong create options")

SHOW WARNINGS;
+---------+------+-----------------------------------------------------------------------+
| Level   | Code | Message                                                               |
+---------+------+-----------------------------------------------------------------------+
| Warning |  140 | InnoDB: ENCRYPTED=NO implies ENCRYPTION_KEY_ID=1                      |
| Warning |  140 | InnoDB: ENCRYPTED=NO cannot be used with innodb_encrypt_tables=FORCE |
| Error   | 1005 | Can't create table `db1`.`tab1` (errno: 140 "Wrong create options")  |
| Warning | 1030 | Got error 140 "Wrong create options" from storage engine InnoDB      |
+---------+------+-----------------------------------------------------------------------+
4 rows in set (0.00 sec)
```

When innodb_encrypt_tables is set to `ON` or `FORCE`, then you must ensure that innodb_encryption_threads is set to a non-zero value, so that InnoDB can perform any necessary encryption operations in the background. See background operations for more information about that. innodb_encryption_rotate_key_age must also be set to a non-zero value for the initial encryption operations to happen in the background. See disabling key rotations for more information about that.

Enabling Encryption for Manually Encrypted Tablespaces

If you do not want to automatically encrypt every InnoDB table, then it is possible to manually enable encryption for just the subset of InnoDB tables that you would like to encrypt. MariaDB provides the ENCRYPTED and ENCRYPTION_KEY_ID table options that can be used to manually enable encryption for specific InnoDB tables. These table options can be used with CREATE TABLE and ALTER TABLE statements. These table options can only be used with InnoDB tables that have their own InnoDB's file-per-table tablespaces, meaning that tables that were created with innodb_file_per_table=ON set.

Table Option	Value	Description
ENCRYPTED	YES / NO / DEFAULT	Defines whether or not to encrypt the table. `DEFAULT` means that the decision is based on the global innodb_encrypt_tables setting.
ENCRYPTION_KEY_ID	32-bit integer	Defines the identifier for the encryption key to use

You can manually enable or disable encryption for a table by using the ENCRYPTED table option. If you only need to protect a subset of InnoDB tables with encryption, then it can be a good idea to manually encrypt each table that needs the extra protection, rather than encrypting all InnoDB tables globally with innodb_encrypt_tables. This allows you to balance security with speed, as it means the encryption and decryption performance overhead only applies to those tables that require the additional security.

If a manually encrypted InnoDB table contains a FULLTEXT INDEX, then the internal table for the full-text index will not also be manually encrypted. To encrypt internal tables for InnoDB full-text indexes, you must enable automatic InnoDB encryption by setting innodb_encrypt_tables to `ON` or `FORCE`.

You can also manually specify a encryption key for a table by using the ENCRYPTION_KEY_ID table option. This allows you to use different encryption keys for different tables. For example, you might create a table using a statement like this:

```
CREATE TABLE tab1 (
   id INT PRIMARY KEY,
   str VARCHAR(50)
) ENCRYPTED=YES ENCRYPTION_KEY_ID=100;

SELECT NAME, ENCRYPTION_SCHEME, CURRENT_KEY_ID
FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
WHERE NAME='db1/tab1';
+----------+------------------+----------------+
| NAME     | ENCRYPTION_SCHEME | CURRENT_KEY_ID |
+----------+------------------+----------------+
| db1/tab1 |                1 |            100 |
+----------+------------------+----------------+
```

If the ENCRYPTION_KEY_ID table option is not specified, then the table will be encrypted with the key identified by the innodb_default_encryption_key_id system variable. For example, you might create a table using a statement like this:

```
SET SESSION innodb_default_encryption_key_id=100;

CREATE TABLE tab1 (
   id INT PRIMARY KEY,
   str VARCHAR(50)
) ENCRYPTED=YES;

SELECT NAME, ENCRYPTION_SCHEME, CURRENT_KEY_ID
FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
WHERE NAME='db1/tab1';
+----------+------------------+----------------+
| NAME     | ENCRYPTION_SCHEME | CURRENT_KEY_ID |
+----------+------------------+----------------+
| db1/tab1 |                1 |            100 |
+----------+------------------+----------------+
```

In the event that you have an existing table and you want to manually enable encryption for that table, then you can do the same with an ALTER TABLE statement. For example:

```
CREATE TABLE tab1 (
   id INT PRIMARY KEY,
   str VARCHAR(50)
) ENCRYPTED=NO;

SELECT NAME, ENCRYPTION_SCHEME, CURRENT_KEY_ID
FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
WHERE NAME='db1/tab1';
+----------+------------------+----------------+
| NAME     | ENCRYPTION_SCHEME | CURRENT_KEY_ID |
+----------+------------------+----------------+
| db1/tab1 |                0 |            100 |
+----------+------------------+----------------+

ALTER TABLE tab1
   ENCRYPTED=YES ENCRYPTION_KEY_ID=100;

SELECT NAME, ENCRYPTION_SCHEME, CURRENT_KEY_ID
FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
WHERE NAME='db1/tab1';
+----------+------------------+----------------+
| NAME     | ENCRYPTION_SCHEME | CURRENT_KEY_ID |
+----------+------------------+----------------+
| db1/tab1 |                1 |            100 |
+----------+------------------+----------------+
```

InnoDB does not permit manual encryption changes to tables in the system tablespace using ALTER TABLE. Encryption of the system tablespace can only be configured by setting the value of the innodb_encrypt_tables

system variable. This means that when you want to encrypt or decrypt the system tablespace, you must also set a non-zero value for the innodb_encryption_threads system variable, and you must also set the innodb_system_rotate_key_age system variable to `1` to ensure that the system tablespace is properly encrypted or decrypted by the background threads. See MDEV-14398 for more information.

Enabling Encryption for Temporary Tablespaces

The innodb_encrypt_temporary_tables system variable controls the configuration of encryption for the temporary tablespace. It has the following possible values:

Option	Description
OFF	Disables temporary table encryption.
ON	Enables temporary table encryption.

This system variable can be specified as a command-line argument to mysqld or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
innodb_encrypt_temporary_tables=ON
```

Enabling Encryption for the Redo Log

InnoDB uses the Redo Log in crash recovery. By default, these events are written to file in an unencrypted state. In configuring MariaDB for data-at-rest encryption, ensure that you also enable encryption for the Redo Log.

To encrypt the Redo Log, first stop the server process. Then, set the innodb_encrypt_log to `ON` in a relevant server option group in an option file. For example:

```
[mariadb]
innodb_encrypt_log = ON
```

Then, start MariaDB. When the server starts back up, it checks to recover InnoDB in the event of a crash. Once it is back online, it begins writing encrypted data to the Redo Log.

Key rotation for the Redo Log is supported. See InnoDB Encryption Keys: Key Rotation for more information.

- Disabling InnoDB encryption

This page is licensed: CC BY-SA / Gnu FDL

InnoDB: Encryption Keys

InnoDB uses encryption key management plugins to support the use of multiple encryption keys.

Encryption Keys

Each encryption key has a 32-bit integer that serves as a key identifier.

The default key is set using the innodb_default_encryption_key_id system variable.

Encryption keys can also be specified with the ENCRYPTION_KEY_ID table option for tables that use file-per-table tablespaces.

InnoDB encrypts the temporary tablespace using the encryption key with the ID `1`.

InnoDB encrypts the Redo Log using the encryption key with the ID `1`.

Keys with Manually Encrypted Tablespaces

With tables that use manually enabled encryption, one way to set the specific encryption key for the table is to use the ENCRYPTION_KEY_ID table option. For example:

```
CREATE TABLE tab1 (
   id INT PRIMARY KEY,
   str VARCHAR(50)
) ENCRYPTED=YES ENCRYPTION_KEY_ID=100;

SELECT NAME, ENCRYPTION_SCHEME, CURRENT_KEY_ID
FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
WHERE NAME='db1/tab1';
+----------+------------------+----------------+
| NAME     | ENCRYPTION_SCHEME | CURRENT_KEY_ID |
+----------+------------------+----------------+
| db1/tab1 |                1 |            100 |
+----------+------------------+----------------+
```

If the ENCRYPTION_KEY_ID table option is not set for a table that uses manually enabled encryption, then it will inherit the value from the innodb_default_encryption_key_id system variable. For example:

```
SET SESSION innodb_default_encryption_key_id=100;

CREATE TABLE tab1 (
   id INT PRIMARY KEY,
   str VARCHAR(50)
) ENCRYPTED=YES;

SELECT NAME, ENCRYPTION_SCHEME, CURRENT_KEY_ID
FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
WHERE NAME='db1/tab1';
+----------+------------------+----------------+
| NAME     | ENCRYPTION_SCHEME | CURRENT_KEY_ID |
+----------+------------------+----------------+
| db1/tab1 |                1 |            100 |
+----------+------------------+----------------+
```

Keys with Automatically Encrypted Tablespaces

With tables that use automatically enabled encryption, one way to set the specific encryption key for the table is to use the innodb_default_encryption_key_id system variable. For example:

```
SET GLOBAL innodb_encryption_threads=4;

SET GLOBAL innodb_encrypt_tables=ON;

SET SESSION innodb_default_encryption_key_id=100;

CREATE TABLE tab1 (
   id INT PRIMARY KEY,
   str VARCHAR(50)
);

SELECT NAME, ENCRYPTION_SCHEME, CURRENT_KEY_ID
FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
WHERE NAME='db1/tab1';
+----------+------------------+----------------+
| NAME     | ENCRYPTION_SCHEME | CURRENT_KEY_ID |
+----------+------------------+----------------+
| db1/tab1 |                1 |            100 |
+----------+------------------+----------------+
```

InnoDB tables that are part of the system tablespace can only be encrypted using the encryption key set by the innodb_default_encryption_key_id system variable.

If the table is in a file-per-table tablespace, and if innodb_encrypt_tables is set to `ON` or `FORCE`, and if innodb_encryption_threads is set to a value greater than `0`, then you can also set the specific encryption key for the table by using the ENCRYPTION_KEY_ID table option. For example:

```
SET GLOBAL innodb_encryption_threads=4;

SET GLOBAL innodb_encrypt_tables=ON;

CREATE TABLE tab1 (
   id INT PRIMARY KEY,
   str VARCHAR(50)
) ENCRYPTION_KEY_ID=100;

SELECT NAME, ENCRYPTION_SCHEME, CURRENT_KEY_ID
    -> FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
    -> WHERE NAME='db1/tab1';
+----------+------------------+----------------+
| NAME     | ENCRYPTION_SCHEME | CURRENT_KEY_ID |
+----------+------------------+----------------+
| db1/tab1 |                1 |            100 |
+----------+------------------+----------------+
```

However, if innodb_encrypt_tables is set to `OFF` or if innodb_encryption_threads is set to `0`, then this will not work. See InnoDB Encryption Troubleshooting: Setting Encryption Key ID For an Unencrypted Table for more information.

Key Rotation

Some key management and encryption plugins allow you to automatically rotate and version your encryption keys. If a plugin support key rotation, and if it rotates the encryption keys, then InnoDB's background encryption threads can re-encrypt InnoDB pages that use the old key version with the new key version.

You can set the maximum age for an encryption key using the innodb_encryption_rotate_key_age system variable. When this variable is set to a non-zero value, background encryption threads constantly check pages to determine if any page is encrypted with a key version that's too old. When the key version is too old, any page encrypted with the older version of the key is automatically re-encrypted in the background to use a more current version of the key. Bear in mind, this constant checking can sometimes result in high CPU usage.

Key rotation for the InnoDB Redo Log is only supported in MariaDB 10.4.0 and later. For more information, see MDEV-12041.

In order for key rotation to work, both the backend key management service (KMS) and the corresponding key management and encryption plugin have to support key rotation. See Encryption Key Management: Support for Key Rotation in Encryption Plugins to determine which plugins currently support key rotation.

Disabling Background Key Rotation Operations

In the event that you encounter issues with background key encryption, you can disable it by setting the innodb_encryption_rotate_key_age system variable to `0`. You may find this useful when the constant key version checks lead to excessive CPU usage. It's also useful in cases where your encryption key management plugin does not support key rotation, (such as with the file_key_management plugin). For more information, see MDEV-14180.

There are, however, issues that can arise when the background key rotation is disabled.

Pending Encryption Operations

When updating the value on the innodb_encrypt_tables system variable, InnoDB internally treats the subsequent background operations to encrypt and decrypt tablespaces as background key rotations. See MDEV-14398 for more information.

You can check the status of background encryption operations by querying the INNODB_TABLESPACES_ENCRYPTION table in the information_schema database.

See InnoDB Background Encryption Threads: Checking the Status of Background Operations for some example queries.

For more information, see MDEV-14398.

InnoDB: Disabling Encryption

Overview

Decryption for InnoDB is more complex than Aria because it involves background threads and the Redo Log.

This guide covers the process for safely decrypting InnoDB tablespaces, the system tablespace, and the Redo Log.

> **Warning:**
>
> **Important Safety Precautions**
>
> - Do Not Remove Plugins Early: Keep your Key Management plugin configured and loaded until the very end. If you remove the keys before decryption is complete, the encrypted data will become permanently inaccessible.
> - Order Matters: You must decrypt all tablespaces and the Redo Log before disabling the encryption plugin.

Step 1

Disable automatic encryption.

To stop the server from encrypting new tables and to begin the background decryption process for “automatically” encrypted tables (those where `ENCRYPTED=DEFAULT`), update the global system variables.

```
-- Disable encryption for new tables and the system tablespace
SET GLOBAL innodb_encrypt_tables = OFF;

-- Enable encryption threads to perform the decryption work
SET GLOBAL innodb_encryption_threads = 4;

-- Force rotation to unencrypted state by setting age to 1
SET GLOBAL innodb_encryption_rotate_key_age = 1;
```

To make these changes persistent, update your MariaDB configuration file:

```
[mariadb]
innodb_encrypt_tables = OFF
innodb_encryption_threads = 4
innodb_encryption_rotate_key_age = 1
```

Step 2

Decrypt manually encrypted tables.

Tables created with the explicit option `ENCRYPTED=YES` are not always automatically decrypted by background threads. You must manually issue an `ALTER TABLE` statement for these.

Identify Manually Encrypted Tables

Run this query to find tables that require manual decryption:

```
SELECT TABLE_SCHEMA, TABLE_NAME
FROM information_schema.TABLES
WHERE ENGINE='InnoDB'
  AND (CREATE_OPTIONS LIKE '%ENCRYPTED=YES%' OR CREATE_OPTIONS LIKE '%ENCRYPTION="Y"%');
```

Perform Decryption

For each table identified, run:

```
ALTER TABLE db_name.table_name ENCRYPTED=NO;
```

Step 3

Decrypt the redo log.

The Redo Log must be decrypted separately. This requires a server restart.

The Redo Log is decrypted by ensuring the server can read the existing logs at startup and then configuring it to write new logs in plaintext.

1. Ensure keys are active: Before attempting to disable Redo Log encryption, verify that your key management plugin is fully functional. MariaDB must be able to decrypt the current `ib_logfile` members during the startup/recovery phase.
2. Update Configuration: Change the `innodb_encrypt_log` system variable to `OFF` in your server option file (for instance, `my.cnf`):

   ```
   [mariadb]
   # Ensure the plugin remains loaded for this restart!
   innodb_encrypt_log = OFF
   ```

3. Restart the server – perform a clean restart:

   ```
   sudo systemctl restart mariadb
   ```

   During this restart, MariaDB uses the existing keys to read the encrypted Redo Logs, completes any necessary crash recovery, and then begins writing new Redo Log events in plaintext.

4. Verification: Confirm the status by running:

   ```
   SHOW GLOBAL VARIABLES LIKE 'innodb_encrypt_log';
   ```

   The value should now be `OFF`.

Step 4

Monitor and verify decryption status.

Before removing your encryption keys, you must verify that no tablespaces remain encrypted.

Check Background Progress

Monitor the `INNODB_TABLESPACES_ENCRYPTION` table. Decryption is complete when the count reaches `0`.

```
SELECT COUNT(*) AS "Encrypted_Tablespaces"
FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
WHERE ENCRYPTION_SCHEME != 0 OR ROTATING_OR_FLUSHING != 0;
```

Verify Individual Tables

Ensure that no tables show encryption in their creation options:

```
SELECT TABLE_NAME, CREATE_OPTIONS
FROM information_schema.TABLES
WHERE TABLE_SCHEMA = 'your_database_name';
```

Step 5

Clean up.

Once the count of encrypted tablespaces is `0` and the Redo Log has been rotated (after restart), you can safely:

1. Remove the Encryption Key Management plugin settings from your configuration file.
2. Restart the MariaDB Server one final time.

InnoDB: Background Encryption Threads

InnoDB performs some encryption and decryption operations with background encryption threads. The innodb_encryption_threads system variable controls the number of threads that the storage engine uses for encryption-related background operations, including encrypting and decrypting pages after key rotations or configuration changes, and scrubbing data to permanently delete it.

Background Operations

InnoDB performs the following encryption and decryption operations using background encryption threads:

- When rotating encryption keys, InnoDB's background encryption threads re-encrypt pages that use key versions older than innodb_encryption_rotate_key_age to the new key version.
- When changing the innodb_encrypt_tables system variable to `FORCE`, InnoDB's background encryption threads encrypt the system tablespace and any file-per-table tablespaces that have the ENCRYPTED table option set to `DEFAULT`.
- When changing the innodb_encrypt_tables system variable to `OFF`, InnoDB's background encryption threads decrypt the system tablespace and any file-per-table tablespacs that have the `ENCRYPTED` table option set to `DEFAULT`.

The innodb_encryption_rotation_iops system variable can be used to configure how many I/O operations you want to allow for the operations performed by InnoDB's background encryption threads.

Whenever you change the value on the innodb_encrypt_tables system variable, InnoDB's background encryption threads perform the necessary encryption or decryption operations. Because of this, you must have a non-zero value set for the innodb_encryption_threads system variable. InnoDB also considers these operations to be key

rotations internally. Because of this, you must have a non-zero value set for the innodb_encryption_rotate_key_age system variable. For more information, see disabling key rotations.

Non-Background Operations

InnoDB performs the following encryption and decryption operations **without** using background encryption threads:

- When a file-per-table tablespaces and using ALTER TABLE to manually set the ENCRYPTED table option to `YES`, InnoDB does not use background threads to encrypt the tablespaces.
- Similarly, when using `file-per-table` tablespaces and using ALTER TABLE to manually set the ENCRYPTED table option to `NO`, InnoDB does not use background threads to decrypt the tablespaces.

In these cases, InnoDB performs the encryption or decryption operation using the server thread for the client connection that executes the statement. This means that you can update encryption on file-per-table tablespaces with an ALTER TABLE statement, even when the innodb_encryption_threads and/or the innodb_rotate_key_age system variables are set to `0`.

InnoDB does not permit manual encryption changes to tables in the system tablespace using ALTER TABLE. Encryption of the system tablespace can only be configured by setting the value of the innodb_encrypt_tables system variable. This means that when you want to encrypt or decrypt the system tablespace, you must also set a non-zero value for the innodb_encryption_threads system variable, and you must also set the innodb_system_rotate_key_age system variable to `1` to ensure that the system tablespace is properly encrypted or decrypted by the background threads. See MDEV-14398 for more information.

Checking the Status of Background Operations

InnoDB records the status of background encryption operations in the INNODB_TABLESPACES_ENCRYPTION table in the information_schema database.

For example, to see which InnoDB tablespaces are currently being decrypted or encrypted on by background encryption, you can check which InnoDB tablespaces have the `ROTATING_OR_FLUSHING` column set to `1`:

```
SELECT SPACE, NAME
FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
WHERE ROTATING_OR_FLUSHING = 1;
```

And to see how many InnoDB tablespaces are currently being decrypted or encrypted by background encryption threads, you can call the COUNT() aggregate function.

```
SELECT COUNT(*) AS 'encrypting'
FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
WHERE ROTATING_OR_FLUSHING = 1;
```

And to see how many InnoDB tablespaces are currently being decrypted or encrypted by background encryption threads, while comparing that to the total number of InnoDB tablespaces and the total number of encrypted InnoDB tablespaces, you can join the table with the INNODB_SYS_TABLESPACES table in the information_schema database:

```
/* information_schema.INNODB_TABLESPACES_ENCRYPTION does not always have rows for all tablespaces,
  so let's join it with information_schema.INNODB_SYS_TABLESPACES */
WITH tablespace_ids AS (
   SELECT SPACE
   FROM information_schema.INNODB_SYS_TABLESPACES ist
   UNION
   /* information_schema.INNODB_SYS_TABLESPACES doesn't have a row for the system tablespace (MDEV-20802)
*/
   SELECT 0 AS SPACE
)
SELECT NOW() AS 'time',
   'tablespaces', COUNT(*) AS 'tablespaces',
   'encrypted', SUM(IF(ite.ENCRYPTION_SCHEME IS NOT NULL, ite.ENCRYPTION_SCHEME, 0)) AS 'encrypted',

InnoDB: Encryption Troubleshooting

Wrong Create Options

With InnoDB tables using encryption, there are several cases where a CREATE TABLE or ALTER TABLE statement can throw Error 1005, due to the InnoDB error 140, `Wrong create options`:

```
CREATE TABLE `test`.`table1` ( `id` INT(4) PRIMARY KEY , `name` VARCHAR(50));
ERROR 1005 (HY000): Can't create table `test`.`table1` (errno: 140 "Wrong create options")
```

When this occurs, you can usually get more information about the cause of the error by following it with a SHOW WARNINGS statement.

This error is known to occur in the following cases:

- Encrypting a table by setting the ENCRYPTED table option to `YES` when the innodb_file_per_table is set to `OFF`.In this case, SHOW WARNINGS would return the following:

```
SHOW WARNINGS;
+---------+------+-------------------------------------------------------------------------+
| Level   | Code | Message                                                                 |
+---------+------+-------------------------------------------------------------------------+
| Warning |  140 | InnoDB: ENCRYPTED requires innodb_file_per_table                        |
| Error   | 1005 | Can't create table `db1`.`tab3` (errno: 140 "Wrong create options") |
| Warning | 1030 | Got error 140 "Wrong create options" from storage engine InnoDB     |
+---------+------+-------------------------------------------------------------------------+
3 rows in set (0.00 sec)
```

- Encrypting a table by setting the ENCRYPTED table option to `YES`, and the innodb_default_encryption_key_id system variable or the ENCRYPTION_KEY_ID table option refers to a non-existent key identifier. In this case, SHOW WARNINGS would return the following:

```
SHOW WARNINGS;
+---------+------+-------------------------------------------------------------------------+
| Level   | Code | Message                                                                 |
+---------+------+-------------------------------------------------------------------------+
| Warning |  140 | InnoDB: ENCRYPTION_KEY_ID 500 not available                             |
| Error   | 1005 | Can't create table `db1`.`tab3` (errno: 140 "Wrong create options") |
| Warning | 1030 | Got error 140 "Wrong create options" from storage engine InnoDB     |
+---------+------+-------------------------------------------------------------------------+
3 rows in set (0.00 sec)
```

- In some versions, this could happen while creating a table with the ENCRYPTED table option set to `DEFAULT` while the innodb_encrypt_tables system variable is set to `OFF`, and the innodb_default_encryption_key_id system variable or the ENCRYPTION_KEY_ID table option are not set to `1`. In this case, SHOW WARNINGS would return the following:

```
SHOW WARNINGS;
+---------+------+----------------------------------------------------------------------+
| Level   | Code | Message                                                              |
+---------+------+----------------------------------------------------------------------+
| Warning |  140 | InnoDB: innodb_encrypt_tables=OFF only allows ENCRYPTION_KEY_ID=1    |
| Error   | 1005 | Can't create table `db1`.`tab3` (errno: 140 "Wrong create options") |
| Warning | 1030 | Got error 140 "Wrong create options" from storage engine InnoDB      |
+---------+------+----------------------------------------------------------------------+
3 rows in set (0.00 sec)
```

Creating a table with the ENCRYPTED table option set to `DEFAULT` while the innodb_encrypt_tables system variable is set to `OFF`, and the innodb_default_encryption_key_id system variable or the ENCRYPTION_KEY_ID table option are **not** set to `1` no longer fail, and it no longer throws a warning.

For more information, see MDEV-18601.

Setting Encryption Key ID For an Unencrypted Table

If you set the ENCRYPTION_KEY_ID table option for a table that is unencrypted because the innodb_encrypt_tables system variable is set to `OFF` and the ENCRYPTED table option set to `DEFAULT`, then this encryption key ID will be saved in the table's `.frm` file, but the encryption key will not be saved to the table's `.ibd` file.

As a side effect, with the current encryption design, if the innodb_encrypt_tables system variable is later set to `ON`, and InnoDB goes to encrypt the table, then the InnoDB background encryption threads will not read this encryption key ID from the `.frm` file. Instead, the threads may encrypt the table with the encryption key with ID `1`, which is internally considered the default encryption key when no key is specified. For example:

```
SET GLOBAL innodb_encrypt_tables=OFF;

CREATE TABLE tab1 (
   id INT PRIMARY KEY,
   str VARCHAR(50)
) ENCRYPTION_KEY_ID=100;

SET GLOBAL innodb_encrypt_tables=ON;

SELECT NAME, ENCRYPTION_SCHEME, CURRENT_KEY_ID
FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
WHERE NAME='db1/tab1';
+----------+-------------------+----------------+
| NAME     | ENCRYPTION_SCHEME | CURRENT_KEY_ID |
+----------+-------------------+----------------+
| db1/tab1 |                 1 |              1 |
+----------+-------------------+----------------+
```

A similar problem is that, if you set the ENCRYPTION_KEY_ID table option for a table that is unencrypted because the ENCRYPTED table option is set to `NO`, then this encryption key ID will be saved in the table's `.frm` file, but the encryption key will not be saved to the table's `.ibd` file.

Recent versions of MariaDB will throw warnings in the case where the ENCRYPTED table option is set to `NO`, but they will allow the operation to succeed. For example:

```
CREATE TABLE tab1 (
   id INT PRIMARY KEY,
   str VARCHAR(50)
) ENCRYPTED=NO ENCRYPTION_KEY_ID=100;
Query OK, 0 rows affected, 1 warning (0.01 sec)

SHOW WARNINGS;
+---------+------+-----------------------------------------------------+
| Level   | Code | Message                                             |
+---------+------+-----------------------------------------------------+
| Warning |  140 | InnoDB: ENCRYPTED=NO implies ENCRYPTION_KEY_ID=1 |
+---------+------+-----------------------------------------------------+
1 row in set (0.00 sec)
```

However, in this case, if you change the ENCRYPTED table option to `YES` or `DEFAULT` with ALTER TABLE, then it will actually use the proper key. For example:

```
SET GLOBAL innodb_encrypt_tables=ON;

ALTER TABLE tab1 ENCRYPTED=DEFAULT;

SELECT NAME, ENCRYPTION_SCHEME, CURRENT_KEY_ID
FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
WHERE NAME = 'db1/tab1';
+----------+------------------+---------------+
| NAME     | ENCRYPTION_SCHEME | CURRENT_KEY_ID |
+----------+------------------+---------------+
| db1/tab1 |                1 |            100 |
+----------+------------------+---------------+
```

For more information, see MDEV-17230, MDEV-18601, and MDEV-19086.

Tablespaces Created on MySQL 5.1.47 or Earlier

MariaDB's data-at-rest encryption implementation reused previously unused fields in InnoDB's buffer pool pages to identify the encryption key version and the post-encryption checksum. Prior to MySQL 5.1.48, these unused fields were not initialized in memory due to performance concerns. These fields still had zero values most of the time, but since they were not explicitly initialized, that means that these fields could have occasionally had non-zero values that could have been written into InnoDB's tablespace files. If MariaDB were to encounter an unencrypted page from a tablespace file that was created on an early version of MySQL that also had non-zero values in these fields, then it would mistakenly think that the page was encrypted.

The fix for MDEV-12112 changed the way that MariaDB distinguishes between encrypted and unencrypted pages, so that it is less likely to mistake an unencrypted page for an encrypted page.

If innodb_checksum_algorithm is set to `full_crc32` or `strict_full_crc32`, and if the table does not use ROW_FORMAT=COMPRESSED, then data files are guaranteed to be zero-initialized.

For more information, see MDEV-18097.

Spatial Indexes

Support for encrypting spatial indexes. To enable, set the innodb_checksum_algorithm to `full_crc32` or to `strict_full_crc32`. Note that MariaDB only encrypts spatial indexes when the ROW_FORMAT table option is **not** set to COMPRESSED.

For more information, see MDEV-12026.

Managing CPU Usage During InnoDB Encryption Operations

When encryption threads are enabled for InnoDB tables, the system initiates background threads to encrypt existing tablespace pages. During this initial process, you may see significant spikes in CPU and I/O usage. This can occur due to:

- **Periodic key rotation checks** that trigger re-encryption work.
- **Large datasets** being encrypted, especially if many tables are enabled at once.
- **Clustered environments** such as MariaDB Galera Cluster, where each node performs encryption operations independently.

CPU usage can increase under several conditions. Common contributing factors are included below.

Causes of CPU Spikes

CPU usage increases during table encryption due to the following factors:

- **CPU usage spikes after enabling encryption**: This is expected because InnoDB must begin encrypting existing tablespace pages in the background once encryption is turned on. The initial workload is heavy.
- **Increased disk I/O activity**: The process involves reading unencrypted pages, encrypting them, and writing them back as encrypted. This read–encrypt–write cycle generates both CPU load (for encryption) and disk I/O load (for page movement).
- **Background threads encrypting tablespace pages:** InnoDB background threads actively encrypt tablespace pages that were encrypted before encryption was enabled. If too many threads are active or configured aggressively, they compete for CPU resources, causing spikes.
- **Performance degradation during initial encryption**: The initial stage of encrypting large tablespaces is the most resource-intensive phase. Once completed, ongoing CPU usage stabilizes, but during the initial encryption, performance can degrade significantly.

This behavior is normal during the one-time setup phase when InnoDB begins encrypting existing tablespace pages. However, the impact can be reduced through:

- **Tuning** system variables such as `innodb_encryption_threads`, `innodb_encryption_rotation_iops`, and `innodb_encryption_rotate_key_age`.
- **Monitoring** background encryption activity to check progress and identify bottlenecks.
- **Phased rollout** of encryption, enabling it for a subset of tables at a time rather than all tables at once. See the Operational Best Practices section.

Configuration Options

Monitor Background Encryption Activity

MariaDB performs encryption in background threads. This helps determine if CPU usage is due to ongoing table encryption or key rotation.

Before changing configuration, verify whether background encryption is currently running by executing the following command:

```
SHOW ENGINE INNODB STATUS
```

You can review the encryption activity output.

Additionally, you can check the essential encryption-related status variables, as detailed in InnoDB: Background Encryption Threads.

Disable Key Rotation Checks

The `innodb_encryption_rotate_key_age` system variable manages how often InnoDB checks tablespace pages to determine whether they need to be re-encrypted with a new key.

Setting this variable to `0` disables automatic key rotation checks if you do not require periodic re-encryption of old pages:

```
SET GLOBAL innodb_encryption_rotate_key_age=0;
```

Once disabled, key rotation checks can significantly reduce CPU usage. See innodb_encryption_rotate_key_age.

Limit Background Encryption Threads

The `innodb_encryption_threads` system variable controls the number of background encryption threads.

Lowering this value can prevent CPU contention at the cost of slower encryption progress.

```
SET GLOBAL innodb_encryption_threads=2;
```

You can maintain the value based on available CPU capacity and workload requirements. See innodb_encryption_threads.

Reduce Encryption Rotation IOPS

The `innodb_encryption_rotation_iops` system variable defines the maximum number of I/O operations per second that InnoDB background threads can use for page encryption and key rotation tasks.

Effect of Lowering the Value:

- **Reduces CPU usage:** fewer encryption operations are performed per second, lowering the load on CPU resources.
- **Lowers disk pressure:** decreases the number of read/write operations, reducing contention on storage I/O.

```
SET GLOBAL innodb_encryption_rotation_iops=50;
```

Setting a lower value (e.g., 25 or 50) limits the threads, making them read and write data more slowly, reducing both I/O and the associated CPU overhead. See innodb_encryption_rotation_iops.

Operational Best Practices

In addition to configuration changes, you can also manage encryption more effectively by applying the following operational practices:

- Encrypt table in batches: Instead of enabling encryption for all tables at once, apply it in stages. This allow background encryption to complete for one set of tables and then proceed with more. With this approach, peak CPU and I/O load can be reduced.
- Galera Cluster setup considerations:
  - Encryption operations are performed independently on each node
  - Use an odd number of nodes (3, 5, 7) to maintain quorum and prevent split-brain scenarios. See Weighted Quorum for details.

Encryption Key Management

MariaDB's data-at-rest encryption requires the use of a key management and encryption plugin. These plugins are responsible both for the management of encryption keys and for the actual encryption and decryption of data.

MariaDB supports the use of multiple encryption keys. Each encryption key uses a 32-bit integer as a key identifier. If the specific plugin supports key rotation, then encryption keys can also be rotated, which creates a new version of the encryption key.

Supported Key Management Plugins list

Plugin	Status	Key Rotation Support	Notes
File-based key management	Supported	Supported from MariaDB Enterprise Server 11.8	Simple but lacks rotation
HashiCorp Vault plugin	Supported, Recommended	Yes	Best for secure, scalable deployments

Choosing an Encryption Key Management Solution

How MariaDB manages encryption keys depends on which encryption key management solution you choose. Currently, MariaDB has three options:

File Key Management Plugin

The File Key Management plugin that ships with MariaDB is a basic key management and encryption plugin that reads keys from a plain-text file. It can also serve as an example and as a starting point when developing a key management plugin.

For more information, see File Key Management Plugin.

Hashicorp Key Management Plugin

Integrates MariaDB encryption with Vault for secure key management.

For more information, refer to the Hashicorp Key Management Plugin.

AWS Key Management Plugin

The AWS Key Management plugin is a key management and encryption plugin that uses the Amazon Web Services (AWS) Key Management Service (KMS). The AWS Key Management plugin depends on the AWS SDK for C++, which uses the Apache License, Version 2.0. The license is not compatible with MariaDB Server's GPL 2.0 license, so we are not able to distribute packages that contain the AWS Key Management plugin. Therefore, the only way to currently obtain the plugin is to install it from the source.

For more information, see AWS Key Management Plugin.

Using Multiple Encryption Keys

Key management and encryption plugins support using multiple encryption keys. Each encryption key can be defined with a different 32-bit integer as a key identifier.

The support for multiple keys opens up some potential use cases. For example, let's say that a hypothetical key management and encryption plugin is configured to provide two encryption keys. One encryption key might be intended for "low security" tables. It could use short keys, which might not be rotated, and data could be encrypted with a fast encryption algorithm. Another encryption key might be intended for "high security" tables. It could use long keys, which are rotated often, and data could be encrypted with a slower but more secure encryption algorithm. The user would specify the identifier of the key that they want to use for different tables, only using high-level security where it's needed.

There are two encryption key identifiers that have special meanings in MariaDB. An encryption key `1` is intended for encrypting system data, such as InnoDB redo logs, binary logs, and so on. It must always exist when data-at-rest encryption is enabled. An encryption key `2` is intended for encrypting temporary data, such as temporary files and Aria internal temporary tables. It is optional. If it doesn't exist, then MariaDB uses an encryption key `1` for these purposes instead. (InnoDB temporary tables, encrypted with `innodb_encrypt_temporary_tables`, always use key `1`, as they share the redo-log encryption key.)

When encrypting InnoDB tables, the key that is used to encrypt tables can be changed.

When encrypting Aria tables, the key that is used to encrypt tables cannot currently be changed.

Key Rotation

Encryption key rotation is optional in MariaDB Server. Key rotation is only supported if the backend key management service (KMS) supports key rotation and if the corresponding key management and encryption plugin for MariaDB also supports key rotation. When a key management and encryption plugin supports key rotation, users can opt to rotate one or more encryption keys, which creates a new version of each rotated encryption key.

Key rotation allows users to improve data security in the following ways:

- If the server is configured to automatically re-encrypt table data with the newer version of the encryption key after the key is rotated, then that prevents an encryption key from being used for long periods of time.
- If the server is configured to simultaneously encrypt table data with multiple versions of the encryption key after the key is rotated, then that prevents all data from being leaked if a single encryption key version is compromised.

The InnoDB storage engine has background encryption threads that can automatically re-encrypt pages when key rotations occur.

The Aria storage engine does not currently have a similar mechanism to re-encrypt pages in the background when key rotations occur.

Support for Key Rotation in Encryption Plugins

Encryption Plugins with Key Rotation Support

- The AWS Key Management Service (KMS) supports encryption key rotation, and the corresponding AWS Key Management Plugin also supports encryption key rotation.
- **HashiCorp Key Management Plugin**: The HashiCorp Key Management Plugin integrates MariaDB with Hashicorp Key Management Plugin for centralized encryption key storage and lifecycle management environments.

Encryption Plugins without Key Rotation Support

- The File Key Management Plugin does not support encryption key rotation because it does not use a backend key management service (KMS).

Encryption Plugin API

New key management and encryption plugins can be developed using the encryption plugin API.

This page is licensed: CC BY-SA / Gnu FDL

File Key Management Encryption Plugin

MariaDB's data-at-rest encryption requires the use of a key management and encryption plugin. These plugins are responsible both for the management of encryption keys and for the actual encryption and decryption of data.

MariaDB supports the use of multiple encryption keys. Each encryption key uses a 32-bit integer as a key identifier. If the specific plugin supports key rotation, then encryption keys can also be rotated, which creates a new version of the encryption key.

The File Key Management plugin that ships with MariaDB is a key management and encryption plugin that reads encryption keys from a plaintext file.

Overview

The File Key Management plugin is the key management and encryption plugin for users who want to use data-at-rest encryption. Some of the plugin's primary features are:

- It reads encryption keys from a plain-text key file.
- As an extra protection mechanism, the plain-text key file can be encrypted.
- It supports multiple encryption keys.
- It supports key rotation with MariaDB Enterprise Server from MariaDB Enterprise Server 11.8.
- It supports two different algorithms for encrypting data.

It can also serve as an example and as a starting point when developing a key management and encryption plugin with the encryption plugin API.

Installing the File Key Management Plugin's Package

The File Key Management plugin is included in MariaDB packages as the `file_key_management.so` or `file_key_management.dll` shared library. The shared library is in the main server package, so no additional package installations are necessary. The plug-in must be installed into MariaDB however as follows.

Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. The plugin can be installed by providing the –plugin-load or the –plugin-load-add options. This can be specified as a command-line argument to mariadbd or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
plugin_load_add = file_key_management
```

Uninstalling the Plugin

Before you uninstall the plugin, you should ensure that data-at-rest encryption is completely disabled, and that MariaDB no longer needs the plugin to decrypt tables or other files.

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN. For example:

```
UNINSTALL SONAME 'file_key_management';
```

If you installed the plugin by providing the –plugin-load or the –plugin-load-add options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Creating the Key File

In order to encrypt your tables with encryption keys using the File Key Management plugin, create the file containing the encryption keys. File name and location don't matter; see in the following what configuration is needed.

For each encryption key, the file contains these options, separated by a semicolon:

- The key identifier (format: 32-bit integer)
- The key version (optional, and only available as of Enterprise Server 11.8)
- The key itself (format: hex-encoded)

Entries look like this:

> **CURRENT ENTERPRISE SERVER**
>
> ```
> <encryption_key_id>;<encryption_key_version>;<hex-encoded_encryption_key>
> ```
>
> **COMMUNITY SERVER & ENTERPRISE SERVER < 11.8**
>
> ```
> <encryption_key_id>;<hex-encoded_encryption_key>
> ```

You can also optionally encrypt the key file to make it less accessible from the file system. That is explained further in the section below.

The File Key Management plugin uses Advanced Encryption Standard (AES) to encrypt data. It supports 128-bit, 192-bit, and 256-bit encryption keys, just like the plugin does.

Generate random encryption keys using the openssl rand command. To create a random 256-bit (32-byte) encryption key, run the following command:

```
$ openssl rand -hex 32
a7addd9adea9978fda19f21e6be987880e68ac92632ca052e5bb42b1a506939a
```

The key file needs to have a key identifier for each encryption key added to the beginning of each line. Key identifiers do not have to be contiguous. For example, to append three new encryption keys to a new key file, issue these commands:

CURRENT ENTERPRISE SERVER

```
mkdir -p /etc/mysql/encryption
echo $(echo -n "1;1;" ; openssl rand -hex 32) | sudo tee -a /etc/mysql/encryption/keyfile.txt
echo $(echo -n "2;1;" ; openssl rand -hex 32) | sudo tee -a /etc/mysql/encryption/keyfile.txt
echo $(echo -n "100;2;" ; openssl rand -hex 32) | sudo tee -a /etc/mysql/encryption/keyfile.txt
```

COMMUNITY SERVER(ALL) & ENTERPRISE SERVER < 11.8

```
mkdir -p /etc/mysql/encryption
echo $(echo -n "1;" ; openssl rand -hex 32) | sudo tee -a /etc/mysql/encryption/keyfile.txt
echo $(echo -n "2;" ; openssl rand -hex 32) | sudo tee -a /etc/mysql/encryption/keyfile.txt
echo $(echo -n "100;" ; openssl rand -hex 32) | sudo tee -a /etc/mysql/encryption/keyfile.txt
```

The resulting key file looks like this:

CURRENT ENTERPRISE SERVER

```
1;1;a7addd9adea9978fda19f21e6be987880e68ac92632ca052e5bb42b1a506939a
2;1;49c16acc2dffe616710c9ba9a10b94944a737de1beccb52dc1560abfdd67388b
100;2;8db1ee74580e7e93ab8cf157f02656d356c2f437d548d5bf16bf2a56932954a3
```

COMMUNITY SERVER & ENTERPRISE SERVER < 11.8

```
1;a7addd9adea9978fda19f21e6be987880e68ac92632ca052e5bb42b1a506939a
2;49c16acc2dffe616710c9ba9a10b94944a737de1beccb52dc1560abfdd67388b
100;8db1ee74580e7e93ab8cf157f02656d356c2f437d548d5bf16bf2a56932954a3
```

The key identifiers give you a way to reference the encryption keys from MariaDB. In the example above, you could reference these encryption keys using the key identifiers `1`, `2` or `100` with the ENCRYPTION_KEY_ID table option or with system variables such as innodb_default_encryption_key_id. You do not necessarily need multiple encryption keys; an encryption key with the key identifier `1` is the only mandatory one.

If the key file is left unencrypted, the File Key Management plugin only requires the file_key_management_filename system variable to be configured.

This system variable can be specified as a command-line argument to `mariadbd`, or it can be specified in a server option group of an option file, like this:

```
[mariadb]
loose_file_key_management_filename = /etc/mysql/encryption/keyfile
```

> **Note:**
>
> To avoid startup failures, the loose option prefix can be specified. No error is produced in case the plugin hasn't been installed yet.

Encrypting the Key File

> **Note:**
>
> This step is optional, but highly recommended.

If you use an unencrypted key file, keys are stored in plain text on your system, posing a security risk. It's recommended to encrypt the key file, with these hints in mind:

- MariaDB only supports the Cipher Block Chaining (CBC) mode of Advanced Encryption Standard (AES).
- The encryption key size can be 128-bits, 192-bits, or 256-bits.
- The encryption key is created from the SHA-1 hash of the encryption password.
- The encryption password has a maximum length of 256 characters.

Generate a random encryption password using the openssl rand command. To create a random 256 character encryption password, execute the following:

```
$ sudo openssl rand -hex 128 > /etc/mysql/encryption/keyfile.key
```

Encrypt the key file using the openssl enc command. To encrypt the key file with the encryption password created in the previous step, execute for example one of the following commands:

CURRENT (>= 12.0.1)

```
$ sudo openssl enc -aes-256-cbc -md sha256 -pbkdf2 \
   -pass file:/etc/mysql/encryption/keyfile.key \
   -in /etc/mysql/encryption/keyfile.txt \
   -out /etc/mysql/encryption/keys.enc

$ sudo openssl enc -aes-256-cbc -md sha256 -iter 20000 \
   -pass file:/etc/mysql/encryption/keyfile.key \
   -in /etc/mysql/encryption/keyfile.txt \
   -out /etc/mysql/encryption/keys.enc
```

> **Note:**
>
> Use the `-iter` (iterations) option with `-pbkdf2` to specify more iterations than the OpenSSL default of `10k`.

> **Warning:**
>
> To use `-pbkdf2` effectively, specify the iteration count on the MariaDB Server side. Without this, key decryption will fail. Use the option `--file_key_management_use_pbkdf2=` *`number_of_iterations`* to set it in MariaDB Server.

< 12.0.1

```
$ sudo openssl enc -aes-256-cbc -md sha1 \
   -pass file:/etc/mysql/encryption/keyfile.key \
   -in /etc/mysql/encryption/keyfile.txt \
   -out /etc/mysql/encryption/keys.enc
```

The resulting `keys.enc` file is the encrypted version of `keys.txt` file. Delete the unencrypted key file.

Having the key file encrypted requires both the file_key_management_filename and the file_key_management_filekey system variables to be configured.

The `file_key_management_filekey` variable can be provided in two forms:

- As a plain-text encryption password. This is not recommended, since the plain-text encryption password would be visible in the output of the SHOW VARIABLES statement.
- Prefixed with `FILE:`, it can be a path to a file that contains the plain-text encryption password.

> **Note:**
>
> `FILE:` must be in uppercase in MariaDB. If you use lowercase instead (like OpenSSL does), errors occur (for instance, `mariadbd: Cannot decrypt ../key.enc. Wrong key?`).

These variables can be specified as command-line arguments to `mariadbd`, or they can be specified in a relevant server option group in an option file:

CURRENT (>= 12.0.1)

```
[mariadb]
...
loose_file_key_management_filename = /etc/mysql/encryption/keyfile.enc
loose_file_key_management_filekey = FILE:/etc/mysql/encryption/keyfile.key
loose_file_key_management_digest = sha256
loose_file_key_management_use_pbkdf2 = 20000
```

< 12.0.1

```
[mariadb]
...
loose_file_key_management_filename = /etc/mysql/encryption/keyfile.enc
loose_file_key_management_filekey = FILE:/etc/mysql/encryption/keyfile.key
```

> **Note:**
>
> To avoid startup failures, the loose option prefix can be specified. No error is produced in case the plugin hasn't been installed yet.

Choosing an Encryption Algorithm

The File Key Management plugin currently supports two encryption algorithms for encrypting data: `AES_CBC` and `AES_CTR`. Both of these algorithms use Advanced Encryption Standard (AES) in different modes. AES uses 128-bit blocks, and supports 128-bit, 192-bit, and 256-bit keys. The modes are:

- The `AES_CBC` mode uses AES in the Cipher Block Chaining (CBC) mode.
- The `AES_CTR` mode uses AES in two slightly different modes in different contexts. When encrypting tablespace pages (such as pages in InnoDB, XtraDB, and Aria tables), it uses AES in the Counter (CTR) mode. When encrypting temporary files (where the cipher text is allowed to be larger than the plain text), it uses AES in the authenticated Galois/Counter Mode (GCM).

The recommended algorithm is `AES_CTR`, but this algorithm is only available when MariaDB is built with OpenSSL. If the server is built with wolfSSL then this algorithm is not available. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.

Configuring the Encryption Algorithm

The encryption algorithm can be configured by setting the file_key_management_encryption_algorithm system variable.

This system variable can be set to one of the following values:

System Variable Value	Description
AES_CBC	Data is encrypted using AES in the Cipher Block Chaining (CBC) mode. This is the default value.
AES_CTR	Data is encrypted using AES either in the Counter (CTR) mode or in the authenticated Galois/Counter Mode (GCM) mode, depending on context. This is only supported in some builds. See the previous section for more information.

This system variable can be specified as command-line arguments to `mariadbd`, or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
loose_file_key_management_encryption_algorithm = AES_CTR
```

Note that the loose option prefix is specified. This option prefix is used in case the plugin hasn't been installed yet.

Note that this variable does not affect the algorithm that MariaDB uses to decrypt the key file. This variable only affects the encryption algorithm that MariaDB uses to encrypt and decrypt data. The only algorithm that MariaDB currently supports to encrypt the key file is Cipher Block Chaining (CBC) mode of Advanced Encryption Standard (AES).

Using the File Key Management Plugin

Once the File Key Management Plugin is enabled, you can use it by creating an encrypted table:

```
CREATE TABLE t (i INT) ENGINE=InnoDB ENCRYPTED=YES
```

Now, table `t` will be encrypted using the encryption key from the key file. For more information on how to use encryption, see Data at Rest Encryption.

> **Note:**
>
> The following Information Schema table is available from MariaDB 11.8.

The Information Schema FILE_KEY_MANAGEMENT_KEYS table provides information about files stored in tablespaces, such as those used by the InnoDB storage engine.

Using Multiple Encryption Keys

The File Key Management Plugin supports using multiple encryption keys. Each encryption key can be defined with a different 32-bit integer as a key identifier.

When encrypting InnoDB tables, the key that is used to encrypt tables can be changed. When encrypting Aria tables, the key that is used to encrypt tables cannot currently be changed.

Key Rotation

> **CURRENT ENTERPRISE SERVER**
>
> The plugin supports key rotation and allows an optional key version in the key file. The keys can be rotated using the `FLUSH FILE_KEY_MANAGEMENT_KEYS` statement, without needing to restart the server. The plugin remains compatible with old key file format, and when version is not specified, it defaults to version 1.

Generation of New Key Versions

How would new key versions be generated?

The plugin doesn't generate any encryption keys itself, and it doesn't have a backend KMS[28] to generate encryption keys for it either.

Any encryption keys need to be generated by the user with external tools, such as OpenSSL. For example:

```
-- Generate a new 256-bit key
openssl rand -hex 32
```

Keys need to be manually saved to the key file. See this section.

The format of the key file is simplistic. It stores encryption keys in a plain-text file.

< 11.8

The File Key Management plugin does not support key rotation.

Versions

Version	Status	Introduced
1.0	Stable	From MariaDB 10.1.18

System Variables

`file_key_management_encryption_algorithm`

- This system variable is used to determine which algorithm the plugin will use to encrypt data.
  - The recommended algorithm is `AES_CTR`, but this algorithm is only available when MariaDB is built with OpenSSL. If the server is built with wolfSSL then this algorithm is not available. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.
- Command line: `--file-key-management-encryption-algorithm=` *`value`*
- Scope: Global
- Dynamic: No
- Data Type: `enumerated`
- Default Value: `AES_CBC`
- Valid Values: `AES_CBC`, `AES_CTR`

`file_key_management_digest`

- Specifies the digest function to use in key derivation of the key used for decrypting the key file.
- Command line: `--file-key-management-digest=` *`value`*
- Scope: Global
- Dynamic: No
- Data type: enumerated
- Default value: sha1
- Valid values: sha1, sha224, sha256, sha384, sha512
- Available from MariaDB 12.0.1

`file_key_management_filekey`

- Used to determine the encryption password that is used to decrypt the key file defined by file_key_management_filename.
  - If this system variable's value is prefixed with `FILE:`, then it is interpreted as a path to a file that contains the plain-text encryption password.
  - If this system variable's value is not prefixed with `FILE:`, then it is interpreted as the plain-text encryption password. However, this is not recommended.
  - The encryption password has a max length of 256 characters.
  - The only algorithm that MariaDB currently supports when decrypting the key file is Cipher Block Chaining (CBC) mode of Advanced Encryption Standard (AES). The encryption key size can be 128-bits, 192-bits, or 256-bits. The encryption key is calculated by taking a SHA-1 hash of the encryption password. Instead of SHA-1, SHA-2 can be used as well.
- Command line: `--file-key-management-filekey=` *`value`*
- Scope: Global
- Dynamic: No
- Data type: `string`
- Default value: (empty)

`file_key_management_filename`

- Used to determine the path to the file that contains the encryption keys. If file_key_management_filekey is set, this file can be encrypted with Cipher Block Chaining (CBC) mode of Advanced Encryption Standard (AES).
- Command line: `--file-key-management-filename=` *`value`*
- Scope: Global
- Dynamic: No
- Data type: `string`
- Default value: (empty)

`file_key_management_use_pbkdf2`

- Specifies whether pbkdf2 is used in key derivation, and if so, how many iterations.
- Command line: `--file-key-management-use-pbkdf2=` *`number`*
- Scope: Global
- Dynamic: No
- Data type: `numeric`
- Default value: 0
- Valid values: integers ≥ 0 (reasonable value: 600000 for sha256, less for sha512)
- Available from MariaDB 12.0.1

Options

`file_key_management`

- Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.

        - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.
    - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- Command line: `--file-key-management=value`
- Data type: `enumerated`
- Default value: `ON`
- Valid values: `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

AWS Key Management Encryption Plugin

Due to license incompatibilities between the MariaDB server source code and the Amazon AWS C++ SDK, we can only distribute the plugin in source code form, and not as ready-to-use binaries. See Installing the Plugin's Package for details.

MariaDB's data-at-rest encryption requires the use of a key management and encryption plugin. These plugins are responsible both for the management of encryption keys and for the actual encryption and decryption of data.

MariaDB supports the use of multiple encryption keys. Each encryption key uses a 32-bit integer as a key identifier. If the specific plugin supports key rotation, then encryption keys can also be rotated, which creates a new version of the encryption key.

The AWS Key Management plugin is a key management and encryption plugin that uses the Amazon Web Services (AWS) Key Management Service (KMS).

Overview

The AWS Key Management plugin uses the Amazon Web Services (AWS) Key Management Service (KMS) to generate and store AES keys on disk, in encrypted form, using the Customer Master Key (CMK) kept in AWS KMS. When MariaDB Server starts, the plugin will decrypt the encrypted keys, using the AWS KMS "Decrypt" API function. MariaDB data will then be encrypted and decrypted using the AES key. It supports multiple encryption keys. It supports key rotation.

Tutorials

Tutorials related to the AWS Key Management plugin can be found at the following pages:

- Amazon Web Services (AWS) Key Management Service (KMS) Encryption Plugin Setup Guide
- Amazon Web Services (AWS) Key Management Service (KMS) Encryption Plugin Advanced Usage

Preparation

- Before you use the plugin, you need to create a Customer Master Key (CMK). Create a key using the AWS Console as described in the AMS KMS developer guide.
- The easiest way to give the AWS key management plugin access to the key is to create an IAM Role with access to the key, and to apply that IAM Role to an EC2 instance where MariaDB Server runs.
- Make sure that MariaDB Server runs under the correct AWS identity that has access to the above key. For example, you can store the AWS credentials in an AWS credentials file for the user who runs `mysqld`. More information about the credentials file can be found in the AWS CLI Getting Started Guide.

Installing the Plugin's Package

The AWS Key Management plugin depends on the AWS SDK for C++, which uses the Apache License, Version 2.0. This license is not compatible with MariaDB Server's GPL 2.0 license, so we are not able to distribute packages that contain the AWS Key Management plugin. Therefore, the only way to currently obtain the plugin is to install it from source.

Installing from Source

When compiling MariaDB from source, the AWS Key Management plugin is built by default, on systems that support it.

Compilation is controlled by the following `cmake` arguments:

- `-DPLUGIN_AWS_KEY_MANAGEMENT=DYNAMIC` to build a loadable plugin library
- `-DAWS_SDK_EXTERNAL_PROJECT=ON` to download the AWS C++ SDK code
- `-DNOT_FOR_DISTRIBUTION=ON` to confirm that you know to not distribute the resulting binaries

The plugin uses AWS C++ SDK, which introduces the following restrictions:

- The plugin can only be built on Windows, Linux, and macOS.
- The plugin requires that one of the following compilers is used: `gcc` 4.8 or later, `clang` 3.3 or later, Visual Studio 2013 or later.
- On Unix, the `libcurl` development package (e.g. `libcurl3-dev` on Debian Jessie), `uuid` development package, and `openssl` need to be installed.
- You may need to use a newer version of `cmake` than is provided by default in your OS.

You do not need to download/install the AWS C++ SDK yourself; the correct version of the SDK GitHub repository will be cloned into the build directory at build time, and only the libraries for AWS components actually needed by the key management plugin will be built, which takes much less time than building the full AWS C++ SDK.

Building on Linux

With all prerequisites installed, the actual build process pretty much comes down to:

```
# clone the MariaDB Server source code repository
git clone https://github.com/MariaDB/server.git
cd server

# prepare the build
mkdir _build
cd _build
cmake .. -DNOT_FOR_DISTRIBUTION=ON \
  -DPLUGIN_AWS_KEY_MANAGEMENT=DYNAMIC \
  -DAWS_SDK_EXTERNAL_PROJECT=1

# build the plugin only
cd plugin/aws_key_management
make
```

Cmake will print the following warning as part of its output. Please take it seriously and do not distribute the `aws_key_management.so` file to any third parties: **You have linked MariaDB with Apache 2.0 libraries! You may not distribute the resulting binary. If you do, you will put yourself into a legal problem with the Free Software Foundation.**

After `make` succeeded you can copy the created `aws_key_management.so` plugin library file to the plugin directory of your actual MariaDB Server machines installation, e.g. `/usr/lib64/mysql/plugin` on RedHat/Fedora based systems or `/usr/lib/mysql/plugin` on Debian-based systems.

Installing the Plugin

Even after the package that contains the plugin's shared library is installed on the operating system, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing INSTALL SONAME or INSTALL PLUGIN. For example:

```
INSTALL SONAME 'aws_key_management';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the –plugin-load or the –plugin-load-add options. This can be specified as a command-line argument to mysqld or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
plugin_load_add = aws_key_management
```

Uninstalling the Plugin

Before you uninstall the plugin, you should ensure that data-at-rest encryption is completely disabled, and that MariaDB no longer needs the plugin to decrypt tables or other files.

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN. For example:

```
UNINSTALL SONAME 'aws_key_management';
```

If you installed the plugin by providing the –plugin-load or the –plugin-load-add options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Configuring the AWS Key Management Plugin

To enable the AWS Key Management plugin, you also need to set the plugin's system variables. The aws_key_management_master_key_id system variable is the primary one to set. These system variables can be specified as command-line arguments to mysqld or they can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
aws_key_management_master_key_id=alias/<your key's alias>
```

Once you've updated the configuration file, restart the MariaDB server to apply the changes and make the key management and encryption plugin available for use.

Using the AWS Key Management Plugin

Once the AWS Key Management Plugin is enabled, you can use it by creating an encrypted table:

```
CREATE TABLE t (i INT) ENGINE=InnoDB ENCRYPTED=YES
```

Now, table `t` will be encrypted using the encryption key generated by AWS.

For more information on how to use encryption, see data-at-rest encryption.

Using Multiple Encryption Keys

The AWS Key Management Plugin supports using multiple encryption keys. Each encryption key can be defined with a different 32-bit integer as a key identifier. If a previously unused identifier is used, then the plugin will

automatically generate a new key.

When encrypting InnoDB tables, the key that is used to encrypt tables can be changed.

When encrypting Aria tables, the key that is used to encrypt tables cannot currently be changed.

Key Rotation

The AWS Key Management plugin does support key rotation. To rotate a key, set the aws_key_management_rotate_key system variable. For example, to rotate key with ID 2:

```
SET GLOBAL aws_key_management_rotate_key=2;
```

Or to rotate all keys, set the value to -1:

```
SET GLOBAL aws_key_management_rotate_key=-1;
```

Versions

Version	Status	Introduced
1.0	Stable	MariaDB 10.2.6, MariaDB 10.1.24
1.0	Beta	MariaDB 10.1.18
1.0	Experimental	MariaDB 10.1.13

System Variables

`aws_key_management_key_spec`

- Description: Encryption algorithm used to create new keys
- Commandline: `--aws-key-management-key-spec=value`
- Scope: Global
- Dynamic: No
- Data Type: `enumerated`
- Default Value: `AES_128`
- Valid Values: `AES_128`, `AES_256`

`aws_key_management_log_level`

- Description: Dump log of the AWS SDK to MariaDB error log. Permitted values, in increasing verbosity, are Off (default), Fatal, Error, Warn, Info, Debug, and Trace.
- Commandline: `--aws-key-management-log-level=value`
- Scope: Global
- Dynamic: No
- Data Type: `enumerated`
- Default Value: `Off`
- Valid Values: `Off`, `Fatal`, `Warn`, `Info`, `Debug` and `Trace`

`aws_key_management_master_key_id`

- Description: AWS KMS Customer Master Key ID (ARN or alias prefixed by alias/) for the master encryption key. Used to create new data keys. If not set, no new data keys will be created.
- Commandline: `--aws-key-management-master-key-id=value`
- Scope: Global

- Dynamic: No
- Data Type: `string`
- Default Value:

`aws_key_management_mock`

- Description: Mock AWS KMS calls (for testing). Must be enabled at compile-time.
- Commandline: `--aws-key-management-mock`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`
- Valid Values: `OFF`, `ON`

`aws_key_management_region`

- Description: AWS region name, e.g us-east-1 . Default is SDK default, which is us-east-1.
- Commandline: `--aws-key-management-region=value`
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value: `'us-east-1'`

`aws_key_management_request_timeout`

- Description: Timeout in milliseconds for create HTTPS connection or execute AWS request. Specify 0 to use SDK default.
- Commandline: `--aws-key-management-request-timeout=value`
- Scope: Global
- Dynamic: No
- Data Type: `integer`
- Default Value: 0

`aws_key_management_rotate_key`

- Description: Set this variable to a data key ID to perform rotation of the key to the master key given in `aws_key_management_master_key_id`. Specify -1 to rotate all keys.
- Commandline: `--aws-key-management-rotate-key=value`
- Scope: Global
- Dynamic: Yes
- Data Type: `integer`
- Default Value:

Options

`aws_key_management`

- Description: Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.

        - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
        - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
        - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.
    - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.

- Commandline: `--aws-key-management=value`
- Data Type: `enumerated`
- Default Value: `ON`
- Valid Values: `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

Amazon Web Services (AWS) Key Management Service (KMS) Encryption Plugin Advanced Usage

This document assumes you've already set up an Amazon Web Services (AWS) account, created a master key in the Key Management Service (KMS), and have done the basic work to set up the MariaDB AWS KMS plugin. These steps are all described in Amazon Web Services (AWS) Key Management Service (KMS) Encryption Plugin Setup Guide.

Ultimately, keeping all the credentials required to read the key on a single host means that a user who has gained access to the host has enough information to read the encrypted files in the datadir, read the encrypted keys from the datadir, interact with AWS KMS to decrypt the encrypted keys, and then used the decrypted keys to decrypt the encrypted data.

Theoretically, a superuser can read the memory of the MariaDB server process to read the decrypted keys or restart MariaDB with password authentication disabled in order to dump data, or add new users to MariaDB in order to allow a user to connect and dump the data. Resolving these issues is beyond the scope of this document. A user who gains root access to your operating system or root access to your MariaDB server will have the ability to decrypt your data. Plan accordingly.

Managing AWS Credentials

Putting the AWS credentials in a file inside the MariaDB home directory is not ideal. By default, any user with the FILE privilege can read any files that the MariaDB server has permission to read, which would include the credentials file. To protect against this, you should set `secure_file_priv` to restrict the location the server will allow a user to read from when executing `LOAD DATA INFILE` or the `LOAD_FILE()` function.

But putting them in other locations requires passing additional data to the server, which in the case of CentOS 7 requires customizing the systemd startup procedure. This is most easily done by creating a "drop-in" file in /etc/systemd/system/mariadb.service.d/. The file should end in ".conf" but can otherwise be named whatever you like. After making any changes to systemd files, execute `systemctl daemon-reload` and then start (or restart) the service as usual.

You can place the credentials file in a location of your choosing and then refer to that file by setting the `AWS_CREDENTIAL_PROFILES_FILE` environment variable in the drop-in file:

```
[Service]
Environment=AWS_CREDENTIAL_PROFILES_FILE=/etc/aws-kms-credentials
```

The credentials file will need to be readable by the "mysql" user, but it does not need to be readable by any other user.

AWS credentials can also be put directly into a “drop-in” systemd file that will be read when starting the MariaDB service:

```
# cat /etc/systemd/system/mariadb.service.d/aws-kms.conf
[Service]
Environment=AWS_ACCESS_KEY_ID=AKIAIRSG2XYZATCJLZ4A
Environment=AWS_SECRET_ACCESS_KEY=ux91LZIxCp4ZXabcdefgIViQNtTan42QAmJqJVqV
```

However, any OS user can read this information from systemd, which could be considered a security risk. Another solution is to put the credentials in a separate file that is only readable by root and then refer to that file using an `EnvironmentFile` directive in a drop-in systemd file.

```
# cat /etc/systemd/system/mariadb.service.d/aws-kms.env
AWS_ACCESS_KEY_ID=AKIAIRSG2XYZATCJLZ4A
AWS_SECRET_ACCESS_KEY=ux91LZIxCp4ZXabcdefgIViQNtTan42QAmJqJVqV

# chown root /etc/systemd/system/mariadb.service.d/aws-kms.env
# chmod 600 /etc/systemd/system/mariadb.service.d/aws-kms.env

# cat /etc/systemd/system/mariadb.service.d/aws-kms.conf
[Service]
EnvironmentFile=/etc/systemd/system/mariadb.service.d/aws-kms.env
```

That has the advantage the credentials can only be read directly by root. systemd adds those variables to the environment of the MariaDB server when starting it, and MariaDB can use the credentials to interact with AWS. Note, though, that any process running as the “mysql” user can still read the credentials from the proc filesystem on Linux.

```
$ whoami
mysql
$ cat /proc/$(pgrep mysqld)/environ | tr '\0' '\n' | grep AWS
AWS_ACCESS_KEY_ID=AKIAIRSG2XYZATCJLZ4A
AWS_SECRET_ACCESS_KEY=ux91LZIxCp4ZXabcdefgIViQNtTan42QAmJqJVqV
```

AWS KMS Key Policy

AWS KMS allows flexible, user-editable key policy. This offers fine-grained control over which users can operate on keys. The possibilities range from simply restricting which IP addresses are allowed to perform operations on the key, to requiring a MFA (Multi-Factor Authentication) device to use the key, to enforcing separation of responsibilities by creating an additional user with limited privileges to enable and disable the key. All 3 of these options will be outlined in this section.

For more details about customizing the Key Policy for your master keys, please consult the AWS Key Management Service Key Policy documentation.

Source IP Restrictions

A simple, common-sense restriction to put in place is to restrict the range of IP addresses that are allowed to use your master key. This way, even if someone obtains API credentials, they’ll be unable to use them to decrypt your encryptions keys from a different host.

To restrict API access from only a specific IP address or range of IP addresses, you’ll need to manually edit the key policy.

1. Load the IAM console at.
2. Click “Encryption Keys” in the left-hand sidebar.
3. Click the name of your encryption key to view its details.
4. Click the link labeled “Switch to policy view”, to the right of the heading of the “Key Policy” section.

5. Locate the section that contains `"Sid": "Allow use of the key"`.
6. Add this text below the `"Sid"` line:

```
"Condition": {
 "IpAddress": {
 "aws:SourceIp": [
 "10.1.2.3/32"
 ]
 }
 },
```

… replacing `10.1.2.3/32` above with an IP address or range of IP addresses in CIDR format. For example, a single address would be `192.168.12.34/32`, while a range of addresses might be `192.168.0.0/24`.

1. Click “Save Changes”.
2. Click “Proceed” if prompted with a warning about using the default view in the future.

Access to the API will now be restricted to requests coming from the IP address or range of IP addresses specified in the policy.

Using a Multi-Factor Authentication (MFA) Device

One approach is to modify the key policy for the master key so that MFA (Multi-Factor Authentication) is required in order to use the key. This is achieved with a wrapper that handles prompting the user for an MFA token, acquires temporary, limited-privilege credentials from the AWS Security Token Service (STS), and puts those credentials into the environment of the MariaDB server process. The credentials can expire after as little as 15 minutes.

To require an MFA token for users of the key, you’ll need to manually edit the key policy.

1. Load the IAM console at.
2. Click “Encryption Keys” in the left-hand sidebar.
3. Click the name of your encryption key to view its details.
4. Click the link labeled “Switch to policy view”, to the right of the heading of the “Key Policy” section.
5. Locate the section that contains `"Sid": "Allow use of the key"`.
6. Add this text below the `"Sid"` line:

```
"Condition": {
 "Bool": {
 "aws:MultiFactorAuthPresent": "True"
 }
 },
```

1. Click “Save Changes”.
2. Click “Proceed” if prompted with a warning about using the default view in the future.

Now, add an MFA device for your user. You’ll need to have a hardware MFA device or an application such as Google Authenticator installed on your smartphone.

1. Click “Users” in the left-hand sidebar.
2. Click the name of your user.
3. Click the “Security Credentials” tab.
4. In the “Sign-In Credentials” section, click the “Manage MFA Device” button.
5. Complete the steps to activate your MFA device.
6. Copy the ARN for your MFA device. You will need to use this when configuring the wrapper program.

Now, set up the wrapper program.

1. Copy the iam-kms-wrapper file to /usr/local/bin/, and ensure that it is executable.
2. Create a drop-in systemd config file in `/etc/systemd/system/mariadb.service.d/`:

```
[Service]
EnvironmentFile=/etc/systemd/system/mariadb.service.d/aws-kms.env
ExecStart=
ExecStart=/usr/local/bin/iam-kms-wrapper --config=/etc/my.cnf.d/iam-kms-wrapper.config /usr/sbin/mysqld
$MYSQLD_OPTS
```

1. Execute `systemctl daemon-reload`.
2. Create a file at `/etc/my.cnf.d/iam-kms-wrapper.config` with these contents, using the ARN for your MFA device as the value for `kms_mfa_id`:

```
[kms]
kms_mfa_id = arn:aws:iam::551888187628:mfa/MDBEnc
kms_mfa_socket = /tmp/kms_mfa_socket
```

When you start the MariaDB service now, the wrapper will temporarily create a socket file at the location given by the `kms_mfa_socket` option. The wrapper will read the MFA code from the socket and will use it to authenticate to KMS. To give the MFA code, simply write the digits to the socket file using `echo`: `echo 111676 > /tmp/kms_mfa_socket`.

The `systemctl` command will block until MariaDB starts, so you will need to write the code to the socket file via a separate terminal.

Note that the temporary credentials put into the environment of the MariaDB process will expire after a period of time defined by the request to the AWS Security Token Service (STS). In the example below, they will expire after 900 seconds. After that time, MariaDB may be unable to generate new encrypted data keys, which means that, for example, an attempt to create a table with a previously-unused key ID would fail.

Wrapper Program Example

Here's an example wrapper program written in go. Build this into an executable named `iam-kms-wrapper` and use it as instructed above. This could of course be written in any language for which an appropriate AWS SDK exists, but go has the benefit of compiling to a static binary, which means you do not have to worry about interpreter versions or installing complex dependencies on the host that runs your MariaDB server.

```
package main

import (
    "syscall"
    "os"
    "log"
    "flag"
    "github.com/aws/aws-sdk-go/aws"
    "github.com/aws/aws-sdk-go/aws/session"
    "github.com/aws/aws-sdk-go/aws/awserr"
    "github.com/aws/aws-sdk-go/service/sts"
    "github.com/robfig/config"
)

func main() {

    config_file_p := flag.String("config", "", "location of the config file")
    flag.Parse()

    if flag.NArg() < 1 {
        log.Fatal("Command to wrap must be given as first command-line argument")
    }

    cmd := flag.Arg(0)
    args := flag.Args()[0:]

    conf, err := config.ReadDefault(*config_file_p)
    if err != nil {
        log.Fatal(err)
    }

    kms_mfa_id, err := conf.String("kms","kms_mfa_id")
    mfa_socket_file, err := conf.String("kms","kms_mfa_socket")

    sess := session.New()
    svc := sts.New(sess)

    syscall.Umask(0044)

    log.Printf("Reading MFA token from %s\n",mfa_socket_file)

    if err := syscall.Mknod(mfa_socket_file, syscall.S_IFIFO|uint32(os.FileMode(0622)), 0); err != nil {
        log.Fatal(err)
    }

    file, err := os.Open(mfa_socket_file)
    if err != nil {
        log.Fatal(err)
    }

    token := make([]byte, 6)

    if _, err := file.Read(token); err != nil {
        log.Fatal(err)
    }

    file.Close()

    if err := syscall.Unlink(mfa_socket_file); err != nil {
        log.Fatal(err)
    }

    mfa_token := string(token)

    token_params := &sts.GetSessionTokenInput{
        DurationSeconds: aws.Int64(900),
        SerialNumber:    aws.String(kms_mfa_id),
        TokenCode:       aws.String(mfa_token),
```

```
    }

    resp, err := svc.GetSessionToken(token_params)
    if err != nil {
        if awsErr, ok := err.(awserr.Error); ok {
            // Prints out full error message, including original error if there was one.
            log.Fatal("Error:", awsErr.Error())
        } else {
            log.Fatal("Error:", err.Error())
        }
    }

    creds := resp.Credentials

    os.Setenv("AWS_ACCESS_KEY_ID",*creds.AccessKeyId)
    os.Setenv("AWS_SECRET_ACCESS_KEY",*creds.SecretAccessKey)
    os.Setenv("AWS_SESSION_TOKEN",*creds.SessionToken)

    execErr := syscall.Exec(cmd, args, os.Environ())
    if execErr != nil {
        panic(execErr)
    }
}
```

Disabling Keys When not Needed

Another possibility is to use the API to disable access to the master key and enable it only when a trusted administrator knows that the MariaDB service needs to be started. A specialized tool on a separate host could be used to enable the key for a very short period of time while the service starts and then quickly disable the key.

To do this, you can create an extra IAM User that can only use the kms:EnableKey and kms:DisableKey API endpoints for your key. This user will not be able to encrypt or decrypt any data using the key.

First, create a new user.

1. Load the IAM console at.
2. Click “Users” in the left-hand sidebar.
3. Click “Create New Users”.
4. Enter a new user name. (The examples will use “MDBEncAdmin”.)
5. Click “Show User Security Credentials”.
6. Copy the credentials and put them in a `credentials` file with this structure:

```
[MDBEncAdmin]
aws_access_key_id=AKIAJMPPNO7EBKABCDEF
aws_secret_access_key=pVdGwbuK5/jG64aBK1oEJOXRlkdM0aAylgabCDef
```

1. Click “Close”.
2. Click “Close” again if prompted.
3. Click the name of your new user to open the details view.
4. Copy the “User ARN” value for your user (for example “arn:aws:iam::551888181234:user/MDBEncAdmin”). You will need this for the next step.

Now, give the new user permission to perform API operations on your key.

1. Click “Encryption Keys” in the left-hand sidebar.
2. Click the name of your key to open the details view.
3. Click “Switch to policy view” if it is not already open. (The “policy view” is a large text field that contains JSON describing the key policy.)
4. Create a new item in the `Statement` array with this structure:

```
{
 "Sid": "Allow Enable and Disable of the key",
 "Effect": "Allow",
 "Principal": {
 "AWS": "arn:aws:iam::551888181234:user/MDBEncAdmin"
 },
 "Action": [
 "kms:EnableKey",
 "kms:DisableKey"
 ]
 },
```

…so that your Key Policy looks like this:

```
{
 "Version": "2012-10-17",
 "Id": "key-consolepolicy-2",
 "Statement": [
 {
 "Sid": "Allow Enable and Disable of the key",
 "Effect": "Allow",
 "Principal": {
 ...
```

1. Click “Save Changes”.

You’ve now added a new IAM user and you’ve given that user privileges to enable and disable your key. This user will be able to perform those operations using the AWS CLI or via a script of your own design using the AWS API. For example, using the AWS CLI:

```
$ cat ~/.aws/credentials
[MDBEncAdmin]
aws_access_key_id=AKIAJMPPNO7EBKABCDEF
aws_secret_access_key=pVdGwbuK5/jG64aBK1oEJOXRlkdM0aAylgabCDef

$ AWS_PROFILE=MDBEncAdmin aws --region us-east-1 kms disable-key --key-id arn:aws:kms:us-east-
1:551888181234:key/abcdf8f6-084b-4cff-99ca-abcdef6c7907c
```

In order for MariaDB to start, this new user will have to enable the master key, then the DBA can start MariaDB, and this user can once again disable the master key after the service has started. Note that in this workflow, MariaDB will be unable to create new encryption keys, such as would be done when a user creates a table that refers to a non-existent key ID. The AWS KMS plugin will encounter an error if it tries to generate a new encryption key while the master key is disabled. In that scenario, the key administrator would have to enable the key before the operation could succeed. Here’s what you should expect to see in the journal if MariaDB tries to interact with a disabled master key:

```
[ERROR] AWS KMS plugin : GenerateDataKeyWithoutPlaintext failed : DisabledException - Unable to parse
ExceptionName: DisabledException Message: arn:aws:kms:us-east-1:551888181234:key/abcdf8f6-084b-4cff-99ca-
abcdef6c7907c is disabled.
```

Adding MFA

It’s also possible to add MFA to this technique so that the user that enables & disables the master key has to authenticate using an MFA device. Adapt the instructions in the MFA section above to add MFA to the policy section for the user with EnableKey and DisableKeys privileges, add an MFA device for that user, use Security Token Service (STS) to get temporary security credentials, and then use those credentials to make the API calls. Here’s an example Python script that follows that workflow:

```
#!/usr/bin/env python

import boto3
import sys

# Command-line argument processing should be more robust than this...
action= sys.argv[1]
mfa_token= sys.argv[2]

# These should perhaps go into a config file instead of here
mfa_serial= 'arn:aws:iam::551888181234:mfa/MDBEncAdmin'
key_id= 'arn:aws:kms:us-east-1:551888181234:key/abcdf8f6-084b-4cff-99ca-abcdef6c7907c'

# Make the connection to the Security Token Service to get temporary credentials
token_client= boto3.client('sts')
token_response= token_client.get_session_token(
    DurationSeconds= 900,
    SerialNumber= mfa_serial,
    TokenCode= mfa_token
)

cred= token_response['Credentials']

# Start new session using temporary, MFA-authenticated credentials
kms_session= boto3.session.Session(
    aws_access_key_id= cred['AccessKeyId'],
    aws_secret_access_key= cred['SecretAccessKey'],
    aws_session_token= cred['SessionToken'],
    region_name= key_id.split(':')[3]
)

# Start KMS client and execute operation against key
kms_client= kms_session.client('kms')
if action == 'enable' or action == 'e':
    action_f= kms_client.enable_key
elif action == 'disable' or action == 'd':
    action_f= kms_client.disable_key
else:
    raise Exception('Action must be either "disable" or "enable"')

action_f(KeyId=key_id)
```

```
$ AWS_PROFILE=MDBEncAdmin python kms-manage-key disable 575290
$ AWS_PROFILE=MDBEncAdmin python kms-manage-key enable 799870
```

Logging and Auditing

CloudTrail

Amazon's CloudTrail service creates JSON-formatted text log files for every API interaction. Enabling CloudTrail requires S3, which incurs additional fees.

First, enable CloudTrail and add a trail.

1. Load the CloudTrail console at.
2. If you've never used CloudTrail before, click "Get Started Now".
3. Enter a value for "trail name". This example uses "mariadb-encryption-key".
4. Create a new S3 bucket, using a globally unique name, or use an existing S3 bucket, according to your needs.
5. Click "Turn On".

If you navigate to the S3 bucket you created, you should find log files that contain JSON-formatted descriptions of your API interactions.

CloudWatch

Amazon's CloudWatch service allows you to create alarms and event rules that monitor log information.

First, send your CloudTrail logs to CloudWatch.

1. Load the CloudTrail console at.
2. Click "Trails" in the left-hand navigation sidebar.
3. Click the name of your trail to open the Configuration view.
4. In the "CloudWatch Logs" section, click "Configure".
5. Click "Continue".
6. Click "Allow".

Now, set up an SNS topic to facilitate email notifications.

1. Open.
2. Make sure the region in the console (look in the upper-right corner) is the same as the region where you created your key!
3. Click "Get Started" is prompted.
4. Click "Events" in the left-hand sidebar.
5. Click "Create new topic".
6. Enter a Topic name of your choosing.
7. Enter a Display name of your choosing.
8. Click "Create topic".
9. Click the ARN of your new SNS topic.
10. Click "Create Subscription".
11. Select "Email" from the Protocol dropdown.
12. Enter the desired notification email address in the Endpoint field.
13. Wait for the confirmation email to show up and follow the instructions.

Now, configure CloudWatch and create an Event Rule.

1. Open.
2. Make sure the region in the console (look in the upper-right corner) is the same as the region where you created your key and your SNS topic!
3. Click "Events" in the left-hand sidebar.
4. Click "Create rule".
5. Choose "AWS API call" from the "Select event source" dropdown.
6. Choose "KMS" from the "Service name" dropdown.
7. Decide which operations should trigger the event. (You can eep "Any operation" selected for simplicity.)
8. Click "Add target".
9. Select "SNS target" from the dropdown.
10. Select the SNS topic you created in the previous steps.
11. Click "Configure details".
12. Enter a Name and Description of your choosing.
13. Click "Create rule".

You should now get emails any time someone executes API calls on the KMS service in the region where you've created the CloudWatch Event rule. That means you should get email any time the key is enabled or disabled, and any time the AWS KMS plugin generates new keys or decrypts the keys stored on disk on the MariaDB server.

You may also wish to create an event rule (or an additional event) that matches only when an unauthorized user tries to access the key. You might accomplish that by manually editing the Event selector of the rule to look something like this:

```
{
  "detail-type": [
    "AWS API Call via CloudTrail"
  ],
  "detail": {
    "eventSource": [
      "kms.amazonaws.com"
    ],
    "errorCode": [
      "AccessDenied",
      "UnauthorizedOperation"
    ]
  }
}
```

The emails are formatted as JSON. Further customization of the CloudWatch email workflow is beyond the scope of this document.

There are many other workflows available using CloudWatch, including workflows with alarms and dashboards. Those are beyond the scope of this document.

Amazon Web Services (AWS) Key Management Service (KMS) Encryption Plugin Setup Guide

Overview

MariaDB contains a robust, full instance, at-rest encryption. This feature uses a flexible plugin interface to allow actual encryption to be done using a key management approach that meets the customer's needs. MariaDB Server includes a plugin that uses the Amazon Web Services (AWS) Key Management Service (KMS) to facilitate separation of responsibilities and remote logging & auditing of key access requests.

Rather than storing the encryption key in a local file, this plugin keeps the master key in AWS KMS. When you first start MariaDB, the AWS KMS plugin will connect to the AWS Key Management Service and ask it to generate a new key. MariaDB will store that key on-disk in an encrypted form. The key stored on-disk cannot be used to decrypt the data; rather, on each startup, MariaDB connects to AWS KMS and has the service decrypt the locally-stored key(s). The decrypted key is stored in-memory as long as the MariaDB server process is running, and that in-memory decrypted key is used to encrypt the local data.

This guide is based on CentOS 7, using systemd with SELinux enabled. Some steps will differ if you use other operating systems or configurations.

Installing the Plugin's Package

The AWS Key Management plugin depends on the AWS SDK for C++, which uses the Apache License, Version 2.0. This license is not compatible with MariaDB Server's GPL 2.0 license, so we are not able to distribute packages that contain the AWS Key Management plugin. Therefore, the only way to currently obtain the plugin is to install it from source.

Installing from Source

When compiling MariaDB from source, the AWS Key Management plugin is built by default on systems that support it.

Compilation is controlled by the `-DPLUGIN_AWS_KEY_MANAGEMENT=DYNAMIC -DAWS_SDK_EXTERNAL_PROJECT=1` cmake arguments.

The plugin uses AWS C++ SDK, which introduces the following restrictions:

- The plugin can only be built on Windows, Linux, and macOS.
- The plugin requires that one of the following compilers is used: `gcc` 4.8 or later, `clang` 3.3 or later, or Visual Studio 2013 or later.
- On Unix, the `libcurl` development package (e.g., `libcurl3-dev` on Debian Jessie), the `uuid` development package, and `openssl` need to be installed.
- You may need to use a newer version of `cmake` than is provided by default in your OS.

Installing the Plugin

Even after the package that contains the plugin's shared library is installed on the operating system, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing INSTALL SONAME or INSTALL PLUGIN. For example:

```
INSTALL SONAME 'aws_key_management';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the –plugin-load or the –plugin-load-add options. This can be specified as a command-line argument to mysqld, or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
plugin_load_add = aws_key_management
```

Sign up for Amazon Web Services

If you already have an AWS account, you can skip this section.

1. Load.
2. Click "Create a Free Account" and complete the steps.
3. You'll need to enter credit card information. Charges related only to your use of the AWS KMS service should be limited to about $1/month for the single master key we will create. If you use other services, additional charges may apply. Consult AWS Cloud Pricing Principles for more information about the pricing of AWS services.
4. You'll need to complete the AWS identity verification process.

Create an IAM User and/or Role

After creating an account or logging in to an existing account, follow these steps to create an IAM User or Role with restricted privileges that will use (but not administer) your master encryption key.

If you intend to run MariaDB Server on an EC2 instance, you should create a Role (or modify an existing Role already attached to your instance). If you intend to run MariaDB Server outside of AWS, you may want to create a User.

Creating an IAM Role

1. Load the Identity and Access Management Console at.
2. Click "Roles" in the left-hand sidebar
3. Click "Create new role"
4. Select "AWS Service Role"

5. Click the “Select” button next to “Amazon EC2 / Allows EC2 instances to call AWS services on your behalf.”
6. Do not select any policies on the “Attach Policy” screen. Click “Next Step”
7. Click “Next Step”
8. Give your Role a “Role name”
9. Click “Create role”

Creating an IAM User

1. Load the Identity and Access Management Console at.
2. Click “Users” in the left-hand sidebar.
3. Click the “Create New Users” button
4. Enter a single User Name of your choosing. We’ll use “MDBEnc” for this demonstration. Keep the “Generate an access key for each user” box checked.
5. Click “Create”.
6. Click “Show User Security Credentials”.
7. Copy the Access Key ID and Secret Access Key. Optionally, you can click “Download Credentials”. We will need these in order for local programs to interact with AWS using its API.
8. Create a file on your computer to hold the credentials for this user. We’ll use this file later. It should have this structure:

```
[default]
aws_access_key_id = AKIAIG6IZ6TKF52FVV5A
aws_secret_access_key = o7CEf7KhZfsVF9cS0a2roqqZNmuzXtIR869zpSBT
```

1. Click “Close”. If prompted because you did not Download Credentials, ensure that you’ve saved them somewhere, and click “Close”.

Create a Master Encryption Key

Now, we’ll create a master encryption key. This key can *never* be retrieved by *any* application or user. This key is used remotely to encrypt (and decrypt) the actual encryption keys that will be used by MariaDB. If this key is deleted or you lose access to it, you will be unable to use the contents of your MariaDB data directory.

1. Click “Encryption Keys” in the left-hand sidebar.
2. Click the “Get Started Now” button.
3. Use the “Filter” dropdown to choose the region where you’d like to create your master key.
4. Click the “Create Key” button.
5. Enter an Alias and Description of your choosing.
6. Click “Next Step”.
7. Do not check the box to make your IAM Role or IAM User a Key Administrator.
8. Click “Next Step” again.
9. Check the boxes to give your IAM Role and/or IAM User permissions to use this key.
10. Click “Next Step”.
11. Click “Finish”.

You should now see your key listed in the console:

You’ll use the “Alias” you provided when you configure MariaDB later.

We now have a Customer Master Key and an IAM user that has privileges to access it using access credentials. This is enough to begin using the AWS KMS plugin.

Configure AWS Credentials

There are a number of ways to give the IAM credentials to the AWS KMS plugin. The plugin supports reading credentials from all standard locations used across the various AWS API clients.

The easiest approach is to run MariaDB Server in an EC2 instance that has an IAM Role with User access to the CMK you wish to use. You can give key access privileges to a Role already attached to your EC2 instance, or you can create a new IAM Role and attach it to an already-running EC2 instance. If you've done that, no further credentials management is required, and you do not need to create a `credentials` file.

If you're not running MariaDB Server on an EC2 instance, you can also place the credentials in the MariaDB data directory. The AWS API client looks for a `credentials` file in the `.aws` subdirectory of the home directory of the user running the client process. In the case of MariaDB, its home directory is its `datadir`.

1. Create a `credentials` file that MariaDB can read. Use the region you selected when creating the key. Master keys cannot be used across regions. For example:

```
$ cat /var/lib/mysql/.aws/credentials
[default]
aws_access_key_id = AKIAIG6IZ6TKF52FVV5A
aws_secret_access_key = o7CEf7KhZfsVF9cS0a2roqqZNmuzXtIR869zpSBT
region = us-east-1
```

1. Change the permissions of the file so that it is owned by, and can only be read by, the `mysql` user:

```
chown mysql /var/lib/mysql/.aws/credentials
chmod 600 /var/lib/mysql/.aws/credentials
```

Configure MariaDB

1. Create a new option file to tell MariaDB to enable encryption functionality and to use the AWS KMS plugin. Create a new file under `/etc/my.cnf.d/` (or wherever your OS may have you create such files) with contents like this:

```
[mariadb]
plugin_load_add = aws_key_management
aws-key-management = FORCE_PLUS_PERMANENT
aws-key-management-master-key-id = alias/mariadb-encryption
aws-key-management-region = us-east-1
!include /etc/my.cnf.d/enable_encryption.preset
```

1. Append the "Alias" value you copied above to `alias/` to use as the value for the `aws-key-management-master-key-id` option.

Note that you **must** include `aws-key-management-region` in your .cnf file if you are not using the us-east-1 region.

Now, you have told MariaDB to use the AWS KMS plugin, and you've put credentials for the plugin in a location where the plugin will find them. The /etc/my.cnf.d/enable_encryption.preset file contains a set of options that enable all available encryption functionality.

When you start MariaDB, the AWS KMS plugin will connect to the AWS Key Management Service and ask it to generate a new key. MariaDB will store that key on-disk in an encrypted form. The key stored on-disk cannot be used to decrypt the data; rather, on each startup, MariaDB must connect to AWS KMS and have the service decrypt the locally-stored key. The decrypted version is stored in-memory as long as the MariaDB server process is running, and that in-memory decrypted key is used to encrypt the local data.

SELinux and Outbound Connections from MariaDB

Because MariaDB needs to connect to the AWS KMS service, you must ensure that the host has outbound network connectivity over port 443 to AWS, and you must ensure that local policies allow the MariaDB server process to make those outbound connections. By default, SELinux restricts MariaDB from making such connections.

The most simple way to cause SELinux to allow outbound HTTPS connections from MariaDB is to enable to mysql_connect_any boolean, like this:

```
setsebool -P mysql_connect_any 1
```

There are more complex alternatives that have a more granular effect, but those are beyond the scope of this document.

Start MariaDB

Start MariaDB using the `systemctl` tool:

```
systemctl start mariadb
```

If you do not use systemd, you may have to start MariaDB using some other mechanism.

You should see journal output similar to this:

```
# journalctl --no-pager -o cat -u mariadb.service

[Note] /usr/sbin/mysqld (mysqld 10.1.9-MariaDB-enterprise-log) starting as process 19831 ...
[Note] AWS KMS plugin: generated encrypted datakey for key id=1, version=1
[Note] AWS KMS plugin: loaded key 1, version 1, key length 128 bit
[Note] InnoDB: Using mutexes to ref count buffer pool pages
[Note] InnoDB: The InnoDB memory heap is disabled
[Note] InnoDB: Mutexes and rw_locks use GCC atomic builtins
[Note] InnoDB: Memory barrier is not used
[Note] InnoDB: Compressed tables use zlib 1.2.7
[Note] InnoDB: Using CPU crc32 instructions
[Note] InnoDB: Initializing buffer pool, size = 2.0G
[Note] InnoDB: Completed initialization of buffer pool
[Note] InnoDB: Highest supported file format is Barracuda.
[Note] InnoDB: 128 rollback segment(s) are active.
[Note] InnoDB: Waiting for purge to start
[Note] InnoDB:  Percona XtraDB (http://www.percona.com) 5.6.26-74.0 started; log sequence number 1616819
[Note] InnoDB: Dumping buffer pool(s) not yet started
[Note] Plugin 'FEEDBACK' is disabled.
[Note] AWS KMS plugin: generated encrypted datakey for key id=2, version=1
[Note] AWS KMS plugin: loaded key 2, version 1, key length 128 bit
[Note] Using encryption key id 2 for temporary files
[Note] Server socket created on IP: '::'.
[Note] Reading of all Master_info entries succeeded
[Note] Added new Master_info '' to hash table
[Note] /usr/sbin/mysqld: ready for connections.
```

Note the several lines of output that refer explicitly to the “AWS KMS plugin”. You can see that the plugin generates a “datakey”, loads that data key, and then later generates and loads a second data key. The 2nd data key is used to encrypt temporary files and temporary tables.

You can see the encrypted keys stored on-disk in the datadir:

```
# ls -l /var/lib/mysql/aws*
-rw-rw----. 1 mysql mysql 188 Feb 25 18:55 /var/lib/mysql/aws-kms-key.1.1
-rw-rw----. 1 mysql mysql 188 Feb 25 18:55 /var/lib/mysql/aws-kms-key.2.1
```

Note that those keys are not useful alone. They are encrypted. When MariaDB starts up, the AWS KMS plugin decrypts those keys by interacting with AWS KMS.

For maximum security, you should start from an empty datadir and run mariadb-install-db after configuring encryption. Then you should re-import your data so that it is fully encrypted. Use `sudo` to run `mariadb-install-db` so that it finds your credentials file:

```
# sudo -u mysql mariadb-install-db
Installing MariaDB/MySQL system tables in '/var/lib/mysql' ...
2016-02-25 23:16:06 139731553998976 [Note] /usr/sbin/mysqld (mysqld 10.1.11-MariaDB-enterprise-log)
starting as process 39551 ...
2016-02-25 23:16:07 139731553998976 [Note] AWS KMS plugin: generated encrypted datakey for key id=1,

Create Encrypted Tables

With `innodb-encrypt-tables=ON`, new InnoDB tables will be encrypted by default, using the key ID set in `innodb_default_encryption_key_id` (default 1). With `innodb-encrypt-tables=FORCE` enabled, it is not possible to manually bypass encryption when creating a table.

You can cause the AWS KMS plugin to create new encryption keys at-will by specifying a new ENCRYPTION_KEY_ID when creating a table:

```
MariaDB [test]> CREATE TABLE t1 (id serial, v VARCHAR(32)) ENCRYPTION_KEY_ID=3;
Query OK, 0 rows affected (0.91 sec)
```

```
[Note] AWS KMS plugin: generated encrypted datakey for key id=3, version=1
[Note] AWS KMS plugin: loaded key 3, version 1, key length 128 bit
```

```
# ls -l /var/lib/mysql/aws*
-rw-rw----. 1 mysql mysql 188 Feb 25 18:55 /var/lib/mysql/aws-kms-key.1.1
-rw-rw----. 1 mysql mysql 188 Feb 25 18:55 /var/lib/mysql/aws-kms-key.2.1
-rw-rw----. 1 mysql mysql 188 Feb 25 19:10 /var/lib/mysql/aws-kms-key.3.1
```

Read more about encrypting data in the Data at Rest Encryption section of the MariaDB Documentation.

AWS KMS Plugin Option Reference

- `aws_key_management_master_key_id`: AWS KMS Customer Master Key ID (ARN or alias prefixed by `alias/`) for master encryption key. Used to create new data keys. If not set, no new data keys will be created.
- `aws_key_management_rotate_key`: Set this variable to a data key ID to perform rotation of the key to the master key given in `aws_key_management_master_key_id`. Specify -1 to rotate all keys.
- `aws_key_management_key_spec`: Encryption algorithm used to create new keys. Allowed values are AES_128 (default) or AES_256.
- `aws_key_management_log_level`: Logging for AWS API. Allowed values, in increasing verbosity, are “Off” (default), “Fatal”, “Error”, “Warn”, “Info”, “Debug”, and “Trace”.

Next Steps

For more information about advanced usage, including strategies to manage credentials, enforce separation of responsibilities, and even require 2-factor authentication to start your MariaDB server, please review Amazon Web Services (AWS) Key Management Service (KMS) Encryption Plugin Advanced Usage.

Hashicorp Key Management Plugin

> **Note:**
>
> **Key Rotation and Cache Flushing**
>
> As of MariaDB 12.3, you can manually rotate keys and flush the cache without restarting the server. See Key Rotation and Cache Flushing for details.

> **Note:**
>
> The configured Vault token requires specific read-only permissions. See Required Vault Token Permissions for details to prevent authorization failures during plugin initialization.

The Hashicorp Key Management Plugin is used to implement encryption using keys stored in the Hashicorp Vault KMS. For more information, see Hashicorp Vault and MariaDB, and for how to install Vault, see Install Vault, as well as MySQL/MariaDB Database Secrets Engine.

The current version of this plugin implements the following features:

- Authentication is done using Hashicorp Vault's token authentication method.
- If additional client authentication is required, then the path to the CA authentication bundle file may be passed as a plugin parameter;
- The creation of the keys and their management is carried out using the Hashicorp Vault KMS and its tools.
- The plugin uses libcurl (https) as an interface to the HashiCorp Vault server.
- JSON parsing is performed through the JSON service (through the include/mysql/service_json.h).
- HashiCorp Vault 1.2.4 was used for development and testing.
- As of MariaDB 10.6.24, the plugin is configured to use cached keys for all communication errors, not just for timeouts. This ensures continuous operation when the Vault server is temporarily unreachable.
- As of MariaDB 10.6.24, the default setting for cache usage on error is `ON`.

Since we require support for key versioning, the key-value storage must be configured in Hashicorp Vault as a key-value storage that uses the interface of the second version. For example, you can create it as follows:

```
~$ vault secrets enable -path /test -version=2 kv
```

Key names must correspond to their numerical identifiers. Key identifiers themselves, their possible values, and rules of use are described in more detail in the MariaDB main documentation.

From the point of view of the key-value storage (in terms of Hashicorp Vault), the key is a secret containing one key-value pair with the name "data" and a value representing a binary string containing the key value, for example:

```
~$ vault kv get /test/1

====== Metadata ======
Key              Value
---              -----
created_time     2019-12-14T14:19:19.42432951Z
deletion_time    n/a
destroyed        false
version          1

==== Data ====
Key     Value
---     -----
data    0123456789ABCDEF0123456789ABCDEF
```

Key values are strings containing binary data. MariaDB currently uses the AES algorithm with 256-bit keys as the default encryption method. In this case, the keys that will be stored in the Hashicorp Vault should be 32-byte strings. Most likely, you will use some utilities for creating and administering keys designed to work with Hashicorp Vault. But in the simplest case, keys can be created from the command line through the vault utility, for example, as follows:

```
~$ vault kv put /test/1 data="0123456789ABCDEF0123456789ABCDEF"
```

If you use default encryption (AES), you should ensure that the key length is 32 bytes, as it may fail to use InnoDB as a data storage.

The plugin currently does not unseal Hashicorp Vault on its own; you must do this in advance and on your own.

To use Hashicorp Vault KMS, the plugin must be preloaded and activated on the server. Most of its parameters should not be changed during plugin operation and therefore must be preconfigured as part of the server configuration through configuration file or command line options:

```
--plugin-load-add=hashicorp_key_management.so
--loose-hashicorp-key-management
--loose-hashicorp-key-management-vault-url="$VAULT_ADDR/v1/test"
--loose-hashicorp-key-management-token="$VAULT_TOKEN"
```

Options

The plugin supports the following parameters, which must be set in advance and cannot be changed during server operation:

`hashicorp-key-management-vault-url`

- Description: HTTP[s] URL that is used to connect to the Hashicorp Vault server. It must include the name of the scheme (`https://` for a secure connection) and, according to the API rules for storage of the key-value type in Hashicorp Vault, after the server address, the path must begin with the “/v1/” string (as prefix), for example: `https://127.0.0.1:8200/v1/my_secrets`. By default, the path is not set; therefore, you must replace it with the correct path to your secrets.
- Command line: `--[loose-]hashicorp-key-management-vault-url="<url>"`

`hashicorp-key-management-token`

- Description: An Authentication token that is passed to the Hashicorp Vault in the request header. By default, this parameter contains an empty string, so you must specify the correct value for it, otherwise the Hashicorp Vault server will refuse authorization. Alternatively, you can define an environment variable `VAULT_TOKEN` and store the token there.
- Command line: `--[loose-]hashicorp-key-management-token="<token>"`

`hashicorp-key-management-vault-ca`

- Description: Path to the Certificate Authority (CA) bundle (is a file that contains root and intermediate certificates). By default, this parameter contains an empty string, which means no CA bundle.
- Command line: `--[loose-]hashicorp-key-management-vault-ca="<path>"`

`hashicorp-key-management-timeout`

- Description: Set the duration (in seconds) for the Hashicorp Vault server connection timeout. The default value is 15 seconds. The allowed range is from 1 to 86400 seconds. The user can also specify a zero value, which means the default timeout value set by the libcurl library (currently 300 seconds).
- Command line: `--[loose-]hashicorp-key-management-timeout=<timeout>`

`hashicorp-key-management-max-retries`

- Description: Number of server request retries in case of timeout. Default is three retries.
- Command line: `----[loose-]hashicorp-key-management-max-retries=<retries>`

`hashicorp-key-management-caching-enabled`

- Description: Enable key caching (storing key values received from the Hashicorp Vault server in the local memory). By default, caching is enabled.
- Command line: `--[loose-]hashicorp-key-management-caching-enabled="on"|"off"`

`hashicorp-key-management-use-cache-on-timeout`

- Description: This parameter instructs the plugin to use the key values or version numbers taken from the cache in the event of a timeout when accessing the vault server. By default, this option is disabled. Please note that key values or version numbers will be read from the cache when the timeout expires, only after the number of attempts to read them from the storage server that specified by the –[loose-]hashicorp-key-management-max-retries parameter has been exhausted.
- Command line: `--[loose-]hashicorp-key-management-use-cache-on-timeout="on"|"off"`
- Deprecated in MariaDB 10.11.16

`hashicorp-key-management-cache-timeout`

- Description: The time (in milliseconds) after which the value of the key stored in the cache becomes invalid and an attempt to read this data causes a new request to be sent to the vault server. By default, cache entries become invalid after 60,000 milliseconds (after one minute). If the value of this parameter is zero, then the keys will always be considered invalid, but they still can be used if the vault server is unavailable and the corresponding cache operating mode (`--[loose-]hashicorp-key-management-use-cache-on-timeout="on"`) is enabled.
- As of MariaDB 10.6.24, the default value is 1 year (specified in milliseconds).
- Command line: `--[loose-]hashicorp-key-management-cache-timeout=<timeout>`
- Deprecated in MariaDB 10.11.16

`hashicorp-key-management-cache-version-timeout`

- Description: The time (in milliseconds) after which the information about the latest version number of the key (which is stored in the cache) becomes invalid and an attempt to read this information causes a new request to be sent to the vault server. If the value of this parameter is zero, then information about the latest key version numbers is always considered invalid, unless there is no communication with the vault server, and use of the cache is allowed when the server is unavailable. By default, this parameter is zero, that is, the latest version numbers for the keys stored in the cache are considered always invalid, except when the vault server is unavailable and use of the cache is allowed on server failures.
- Command line: `--[loose-]hashicorp-key-management-cache-version-timeout=<timeout>`

`hashicorp-key-management-check-kv-version`

- Description: This parameter enables (“on”, this is the default value) or disables (“off”) checking the kv storage version during plugin initialization. The plugin requires storage version 2 or later in order for it to work properly.
- When this option is enabled, the configured Vault token must also have read access to the `sys/mounts/my_vault/tune` endpoint, allowing the plugin to determine the kv storage version. See Required Vault Token Permissions for details.
- Command line: `--[loose-]hashicorp-key-management-check-kv-version="on"|"off"`

Required Vault Token Permissions

The token provided through `hashicorp-key-management-token` must have the following Vault access privileges.

Given a `hashicorp-key-management-vault-url` of `http://vault-server/v1/my_vault`, the token requires:

Value Path	Access Required	Condition
`my_vault/data`	read	Always required
`sys/mounts/my_vault/tune`	read	Required unless `hashicorp-key-management-check-kv-version` is set to `off`

Note: During plugin initialization, the kv storage version is verified using the `sys/mounts/my_vault/tune` path. Most configurations require this permission because `hashicorp-key-management-check-kv-version` is set to `on` by default.

Example Minimal Vault Policy for Read-Only Access

The following example provides a minimal Vault policy that grants the required privileges:

```
path "my_vault/data/*" {
  capabilities = ["read"]
}

path "sys/mounts/my_vault/tune" {
  capabilities = ["read"]
}
```

Replace `my_vault` with the path segment of your `hashicorp-key-management-vault-url` configuration.

This ensures that the plugin does not require additional permissions to access encryption keys or verify the kv storage version.

Key Rotation and Cache Flushing

> **Note:**
>
> This functionality is available from MariaDB 12.3.

The HashiCorp Key Management plugin supports key versioning provided by the HashiCorp Vault Server. In previous versions, rotating keys required a server restart to clear the internal cache. As of MariaDB 12.3, you can flush the plugin cache manually while the server is running.

Flushing the Cache

To rotate keys, you must flush the cached keys using the `FLUSH` command. This clears the local cache, forcing the server to re-fetch the latest key versions from the HashiCorp Vault server upon the next access.

Executing this command requires the `RELOAD` privilege.

```
FLUSH HASHICORP_KEY_MANAGEMENT_CACHE;
```

Verifying Key Versions

To view the current Key IDs and Key Versions stored in the latest version cache, you can query the Information Schema table or use the `SHOW` command.

See Information Schema HASHICORP_KEY_MANAGEMENT_CACHE for table details.

Using the SHOW command:

```
SHOW HASHICORP_KEY_MANAGEMENT_CACHE;
```

Uninstall Key Management Plugins

Once all data and logs have been decrypted, you can safely remove key management plugins, if desired. For example, if using the file key management plugin:

```
# Comment out or remove the following lines
plugin_load_add = file_key_management
file_key_management_filename = /etc/mysql/encryption/keyfile
```

Restart the server after editing the configuration.

- Ensure that all tables no longer report encryption in `CREATE_OPTIONS`.
- Confirm that redo logs and binary logs are unencrypted by checking server variables and log headers.
- Confirm that no key management plugin is loaded:

```
SHOW PLUGINS;
```

This page is licensed: CC BY-SA / Gnu FDL

User Account Management

See Roles.

Manage roles in MariaDB Server for streamlined user access control. This section explains how to create, assign, and manage roles to simplify privilege management and enhance security.

See Account Locking.

Explains how to lock and unlock user accounts using CREATE USER and ALTER USER statements to prevent login access without deleting the account.

See Authentication.

Details the authentication changes introduced in MariaDB 10.4, including multiple authentication plugins per user, the mysql.global_priv table, and the default unix_socket authentication for root.

See Incrementing of the access_denied_errors Status Variable.

Describes the conditions that trigger the access_denied_errors status variable, such as failed logins, invalid privileges, or missing SSL requirements, aiding in security monitoring.

See User Password Expiry.

Guide to configuring password expiration policies, including setting global lifetimes via default_password_lifetime or per-user limits, and handling expired password connections.

Roles

See Roles Overview.

Overview of Role-Based Access Control (RBAC) in MariaDB, which simplifies privilege management by allowing permissions to be grouped into roles and assigned to users.

See System Users, Roles, Privileges.

Details default system users like mariadb.sys and the PUBLIC role, including their creation, purpose, and special management behaviors.

See CREATE ROLE.

Create new roles to simplify privilege management. Learn how to define a role that can be assigned to multiple users or other roles.

See DROP ROLE.

Remove a role from the system. Learn the syntax to delete defined roles and revoke them from any users or roles that currently hold them.

See CURRENT_ROLE.

Returns the current role. The current role can be set with SET ROLE or SET DEFAULT ROLE.

See SET ROLE.

Sets the current role for the session. Learn how to enable none, or a specific role to change your current privileges dynamically.

See SET DEFAULT ROLE.

Define the default role for a user. Learn how to configure which role is automatically active when a user connects to the server.

See GRANT.

Complete privilege management guide for MariaDB. Complete GRANT syntax for database, table, and column permissions with roles with comprehensive examples and.

See REVOKE.

Remove privileges or roles. Learn how to withdraw previously granted permissions from users or roles to restrict access and secure the database.

See mysql.roles_mapping Table.

The mysql.roles_mapping table manages role assignments, linking user accounts to the roles they have been granted.

See Information Schema APPLICABLE_ROLES Table.

The Information Schema APPLICABLE_ROLES table shows the role authorizations that the current user may use, detailing grantable and default status.

See Information Schema ENABLED_ROLES Table.

The Information Schema ENABLED_ROLES table lists all roles that are currently enabled for the current session, including nested roles.

This page is licensed: CC BY-SA / Gnu FDL

Roles Overview

Description

A role bundles a number of privileges together. It assists larger organizations where, typically, a number of users would have the same privileges, and, previously, the only way to change the privileges for a group of users was by changing each user's privileges individually.

Alternatively, multiple external users could have been assigned the same user, and there would have been no way to see which actual user was responsible for which action.

With roles, managing this is easy. For example, there could be a number of users assigned to a journalist role, with identical privileges. Changing the privileges for all the journalists is a matter of simply changing the role's privileges, while the individual user is still linked with any changes that take place.

Roles are created with the CREATE ROLE statement, and dropped with the DROP ROLE statement. Roles are then assigned to a user with an extension to the GRANT statement, while privileges are assigned to a role in the regular way with GRANT. Similarly, the REVOKE statement can be used to both revoke a role from a user, or revoke a privilege from a role.

Once a user has connected, he can obtain all privileges associated with a role by **setting** a role with the SET ROLE statement. The CURRENT_ROLE function returns the currently set role for the session, if any.

Only roles granted directly to a user can be set, roles granted to other roles cannot. Instead the privileges granted to a role, which is, in turn, granted to another role (grantee), will be immediately available to any user who sets this second grantee role.

The SET DEFAULT ROLE statement allows one to set a default role for a user. A default role is automatically enabled when a user connects (an implicit SET ROLE statement is executed immediately after a connection is established).

Roles were implemented as a GSoC 2013 project by Vicentiu Ciorbaru.

System Tables

Information about roles and who they've been granted to can be found in the Information Schema APPLICABLE_ROLES table as well as the mysql.ROLES_MAPPING table.

The Information Schema ENABLED_ROLES table shows the enabled roles for the current session.

Examples

Creating a role and granting a privilege:

```
CREATE ROLE journalist;

GRANT SHOW DATABASES ON *.* TO journalist;

GRANT journalist TO hulda;
```

Note, that hulda has no `SHOW DATABASES` privilege, even though she was granted the journalist role. She needs to **set** the role first:

```
SHOW DATABASES;
+--------------------+
| Database           |
+--------------------+
| information_schema |
+--------------------+

SELECT CURRENT_ROLE;
+--------------+
| CURRENT_ROLE |
+--------------+
| NULL         |
+--------------+

SET ROLE journalist;

SELECT CURRENT_ROLE;
+--------------+
| CURRENT_ROLE |
+--------------+
| journalist   |
+--------------+

SHOW DATABASES;
+--------------------+
| Database           |
+--------------------+
| ...                |
| information_schema |
| mysql              |
| performance_schema |
| test               |
| ...                |
+--------------------+

SET ROLE NONE;
```

Roles can be granted to roles:

```
CREATE ROLE writer;

GRANT SELECT ON data.* TO writer;

GRANT writer TO journalist;
```

But one does not need to set a role granted to a role. For example, hulda will automatically get all writer privileges when she sets the journalist role:

```
SELECT CURRENT_ROLE;
+--------------+
| CURRENT_ROLE |
+--------------+
| NULL         |
+--------------+

SHOW TABLES FROM data;
Empty set (0.01 sec)

SET ROLE journalist;

SELECT CURRENT_ROLE;
+--------------+
| CURRENT_ROLE |
+--------------+
| journalist   |
+--------------+

SHOW TABLES FROM data;
+------------------------------+
| Tables_in_data               |
+------------------------------+
| set1                         |
| ...                          |
+------------------------------+
```

Roles and Views (and Stored Routines)

When a user sets a role, he, in a sense, has two identities with two associated sets of privileges.
But a view (or a stored routine) can have only one definer. So, when a view (or a stored routine) is created with the `SQL SECURITY DEFINER`, one can specify whether the definer should be `CURRENT_USER` (and the view will have none of the privileges of the user's role) or `CURRENT_ROLE` (in this case, the view will use role's privileges, but none of the user's privileges). As a result, sometimes one can create a view that is impossible to use.

```
CREATE ROLE r1;

GRANT ALL ON db1.* TO r1;

GRANT r1 TO foo@localhost;

GRANT ALL ON db.* TO foo@localhost;

SELECT CURRENT_USER
+---------------+
| current_user  |
+---------------+
| foo@localhost |
+---------------+

SET ROLE r1;

CREATE TABLE db1.t1 (i INT);

CREATE VIEW db.v1 AS SELECT * FROM db1.t1;

SHOW CREATE VIEW db.v1;
+------+-----------------------------------------------------------------------------------------------------------
----------------------------------------+----------------------+----------------------+
| View | Create View
| character_set_client | collation_connection |
+------+-----------------------------------------------------------------------------------------------------------
----------------------------------------+----------------------+----------------------+
| v1   | CREATE ALGORITHM=UNDEFINED DEFINER=`foo`@`localhost` SQL SECURITY DEFINER VIEW `db`.`v1` AS
SELECT `db1`.`t1`.`i` AS `i` from `db1`.`t1` | utf8                 | utf8_general_ci      |
+------+-----------------------------------------------------------------------------------------------------------
----------------------------------------+----------------------+----------------------+

CREATE DEFINER=CURRENT_ROLE VIEW db.v2 AS SELECT * FROM db1.t1;

SHOW CREATE VIEW db.b2;
+------+-----------------------------------------------------------------------------------------------------------
---------------------------+----------------------+----------------------+
| View | Create View
| character_set_client | collation_connection |
+------+-----------------------------------------------------------------------------------------------------------
---------------------------+----------------------+----------------------+
| v2   | CREATE ALGORITHM=UNDEFINED DEFINER=`r1` SQL SECURITY DEFINER VIEW `db`.`v2` AS select
`db1`.`t1`.`a` AS `a` from `db1`.`t1` | utf8                 | utf8_general_ci      |
+------+-----------------------------------------------------------------------------------------------------------
---------------------------+----------------------+----------------------+
```

System Users, Roles, Privileges

> **Warning:**
>
> The `PUBLIC` role is created implicitly by `GRANT` statements and its creation is not logged, distinguishing it from standard system principals.

MariaDB automatically creates several users and roles for administrative and internal server functions.

System Users

These user accounts are created by the `mariadb-install-db` script during the initial server setup.

`root@localhost`

Creation	Created automatically by `mariadb-install-db`.
Purpose	Serves as the primary administrative account for initial server setup and management.
Management	It is highly recommended to secure this account immediately after installation. *Standard security practices include setting a strong password, renaming the account, or removing it entirely in favor of other named administrative accounts.*

`mariadb.sys@localhost`

Creation	Created automatically by `mariadb-install-db`.
Purpose	A mandatory system user required for internal server operations, such as executing scheduled events.
Management	

System Roles

These roles are built into the server and have special behaviors.

The `PUBLIC` Role

The `PUBLIC` role is a special, built-in concept that represents every user on the server.

Creation

The `PUBLIC` role is created implicitly by the server the first time a `GRANT ... TO PUBLIC` statement is executed. It is not created with `CREATE ROLE`.

Purpose

It provides a convenient way to grant privileges server-wide without having to grant them to each user individually. Privileges granted to `PUBLIC` are inherited by all existing and future users.

Management & Security:

- Because the `PUBLIC` role is created implicitly, its creation is **not written to the audit log or binary log** as a standard DDL event. This is a critical detail for security auditing.
- The `PUBLIC` role cannot be explicitly dropped with `DROP ROLE`.
- To audit the privileges that apply to all users, you must check the grants for `PUBLIC` directly.

Syntax Examples:

```
-- Grant a privilege to all users
GRANT SELECT ON my_app.reports TO PUBLIC;

-- View privileges granted to PUBLIC
SHOW GRANTS FOR PUBLIC;

-- Revoke a privilege from all users
REVOKE SELECT ON my_app.reports FROM PUBLIC;
```

This page is licensed: CC BY-SA / Gnu FDL

Account Locking

Syntax

```
CREATE USER [...]
[lock_option] [password_option]

ALTER USER [...]
[lock_option] [password_option]
```

CURRENT

The *lock_option* and *password_option* clauses can occur in either order.

<10.4.7, < 10.5.8

Prior to MariaDB 10.4.7 and MariaDB 10.5.8, the *lock_option* must be placed before the *password_option*.

Description

Account locking permits privileged administrators to lock/unlock user accounts. No new client connections will be permitted if an account is locked (existing connections are not affected).

Locking Accounts

User accounts can be locked at creation, with the CREATE USER statement, or modified after creation with the ALTER USER statement. For example:

```
CREATE USER 'lorin'@'localhost' ACCOUNT LOCK;
```

or

```
ALTER USER 'marijn'@'localhost' ACCOUNT LOCK;
```

The server will return an `ER_ACCOUNT_HAS_BEEN_LOCKED` error when locked users attempt to connect:

```
mariadb -ulorin
  ERROR 4151 (HY000): Access denied, this account is locked
```

Unlocking Accounts

The ALTER USER statement is used to unlock a user:

```
ALTER USER 'lorin'@'localhost' ACCOUNT UNLOCK;
```

Show Whether a Specific Account is Locked

The SHOW CREATE USER statement will show whether the account is locked:

```
SHOW CREATE USER 'marijn'@'localhost';
+-----------------------------------------------+
| CREATE USER for marijn@localhost              |
+-----------------------------------------------+
| CREATE USER 'marijn'@'localhost' ACCOUNT LOCK |
+-----------------------------------------------+
```

as well as querying the mysql.global_priv table:

```
SELECT CONCAT(user, '@', host, ' => ', JSON_DETAILED(priv))
  FROM mysql.global_priv
  WHERE user='marijn';
+-----------------------------------------------------------------------------------------+
| CONCAT(user, '@', host, ' => ', JSON_DETAILED(priv))                                    |
+-----------------------------------------------------------------------------------------+
| marijn@localhost => {
    "access": 0,
    "plugin": "mysql_native_password",
    "authentication_string": "",
    "account_locked": true,
    "password_last_changed": 1558017158
} |
+-----------------------------------------------------------------------------------------+
```

Find Locked Accounts

This query against the `mysql.global_priv` table will return all accounts which have `"account_locked": true` within the `Priv` json column:

```
SELECT CONCAT(user, '@', host) AS 'Locked Accounts' FROM mysql.global_priv WHERE Priv like
'%account_locked":true%';
```

Example Output:

```
+------------------------+
| Locked Accounts        |
+------------------------+
| mariadb.sys@localhost  |
| bart.simpson@localhost |
+------------------------+
2 rows in set (0.000 sec)
```

Authentication

For Windows, see Authentication Plugin - GSSAPI.

Overview

There are four **new main features in 10.4** relating to authentication:

- It is possible to use more than one authentication plugin for each user account. For example, this can be useful to slowly migrate users to the more secure ed25519 authentication plugin over time, while allowing the old mysql_native_password authentication plugin as an alternative for the transitional period.
- The `root@localhost` user account created by mariadb-install-db is created with the ability to use two authentication plugins.
  - First, it is configured to try to use the unix_socket authentication plugin. This allows the `root@localhost` user to log in without a password via the local Unix socket file defined by the socket system variable, as long as the login is attempted from a process owned by the operating system `root` user account.
  - Second, if authentication fails with the unix_socket authentication plugin, then it is configured to try to use the mysql_native_password authentication plugin. However, an invalid password is initially set, so in order to authenticate this way, a password must be set with SET PASSWORD.

    - However, just using the unix_socket authentication plugin may be fine for many users, and it is very secure. You may want to try going without password authentication to see how well it works for you. Remember, the best way to keep your password safe is not to have one!

- All user accounts, passwords, and global privileges are now stored in the mysql.global_priv table. The mysql.user table still exists and has exactly the same set of columns as before, but it's now a view that references the mysql.global_priv table. Tools that analyze the mysql.user table should continue to work as before. From MariaDB 10.4.13, the dedicated `mariadb.sys` user is created as the definer of this view. Previously, `root` was the definer, which resulted in privilege problems when this username was changed.
- MariaDB 10.4 adds support for User Password Expiry, which is not active by default.

Description

As a result of the above changes, the open-for-everyone all-powerful root account is finally gone. And installation scripts will no longer demand that you "PLEASE REMEMBER TO SET A PASSWORD FOR THE MariaDB root USER!", because the root account is securely created automatically.

Two all-powerful accounts are created by default — root and the OS user that owns the data directory, typically mysql. They are created as:

```
CREATE USER root@localhost IDENTIFIED VIA unix_socket
    OR mysql_native_password USING 'invalid'
CREATE USER mysql@localhost IDENTIFIED VIA unix_socket
    OR mysql_native_password USING 'invalid'
```

Using unix_socket means that if you are the system root user, you can log in as root@localhost without a password. This technique was pioneered by Otto Kekäläinen in Debian MariaDB packages and has been successfully used in Debian since as early as MariaDB 10.0.

It is based on a simple fact that asking the system root for a password adds no extra security — root has full access to all the data files and all process memory anyway. But not asking for a password means there is no root password to forget (no need for the numerous tutorials on "how to reset MariaDB root password"). And if you want to script some tedious database work, there is no need to store the root password in plain text for the script to use (no need for debian-sys-maint user).

Still, some users may wish to log in as MariaDB root without using sudo. Hence the old authentication method — conventional MariaDB password — is still available. By default, it is disabled ("invalid" is not a valid password hash), but one can set the password with a usual SET PASSWORD statement. And still retain the password-less access via sudo.

If you install MariaDB locally (say from a tarball), you will not want to use sudo to be able to log in. This is why MariaDB creates a second all-powerful user with the same name as a system user that owns the data directory. In local (not system-wide) installations, this will be the user who installed MariaDB — they automatically get convenient password-less root-like access, because they can access all the data files anyway.

Even if MariaDB is installed system-wide, you may not want to run your database maintenance scripts as system root — now you can run them as system mysql user. And you will know that they will never destroy your entire system, even if you make a typo in a shell script.

However, seasoned MariaDB DBAs who are used to the old ways do need to make some changes. See the examples below for common tasks.

Cookbook

After installing MariaDB system-wide, the first thing you've got used to doing is logging in to the unprotected root account and protecting it, that is, setting the root password:

```
$ sudo dnf install MariaDB-server
$ mariadb -uroot
...
MariaDB> set password = password("XH4VmT3_jt");
```

This is not only unnecessary now, but it will also simply not work — there is no unprotected root account. To log in as the root user, use

```
$ sudo dnf install MariaDB-server
$ sudo mariadb
```

Note that it implies you are connecting via the unix socket, not tcp. If you happen to have `protocol=tcp` in a system-wide `/etc/my.cnf` file, use `sudo mariadb --protocol=socket`.

After installing MariaDB locally, you've also used it to connect to the unprotected root account using `mariadb -uroot`. This will not work either; simply use `mariadb` without specifying a username.

If you've forgotten your root password, no problem — you can still connect using sudo and change the password. And if you've also removed unix_socket authentication, to restore access, do as follows:

- restart MariaDB with –skip-grant-tables
- log in to the unprotected server
- run FLUSH PRIVILEGES (note, before 10.4, this would've been the last step, not anymore). This disables `--skip-grant-tables` and allows you to change the stored authentication method
- run SET PASSWORD FOR root@localhost to change the root password.

To view inside privilege tables, the old mysql.user table still exists. You can select from it as before, although you cannot update it anymore. It doesn't show alternative authentication plugins, and this was one of the reasons for switching to the mysql.global_priv table — complex authentication rules did not fit into the rigid structure of a relational table. You can select from the new table, for example:

```
SELECT CONCAT(user, '@', host, ' => ', json_detailed(priv)) FROM mysql.global_priv;
```

Reverting to the Previous Authentication Method for root@localhost

If you don't want the `root@localhost` user account created by mariadb-install-db to use unix_socket authentication by default, then there are a few ways to revert to the previous mysql_native_password authentication method for this user account.

Configuring mariadb-install-db to Revert to the Previous Authentication Method

One way to revert to the previous mysql_native_password authentication method for the `root@localhost` user account is to execute mariadb-install-db with a special option. If mariadb-install-db is executed while `--auth-root-authentication-method=normal` is specified, then it will create the default user accounts using the default behavior of MariaDB 10.3 and before.

This means that the `root@localhost` user account will use mysql_native_password authentication by default. There are some other differences as well. See mariadb-install-db: User Accounts Created by Default for more information.

For example, the option can be set on the command-line while running mariadb-install-db:

```
mariadb-install-db --user=mysql --datadir=/var/lib/mysql --auth-root-authentication-method=normal
```

The option can also be set in an option file in an option group supported by mariadb-install-db. For example:

```
[mysql_install_db]
auth_root_authentication_method=normal
```

If the option is set in an option file and if mariadb-install-db is executed, then mariadb-install-db will read this option from the option file, and it will automatically set this option.

Altering the User Account to Revert to the Previous Authentication Method

If you have already installed MariaDB, and if the `root@localhost` user account is already using unix_socket authentication, then you can revert to the old mysql_native_password authentication method for the user account by executing the following:

```
ALTER USER root@localhost IDENTIFIED VIA mysql_native_password
     USING PASSWORD("verysecret")
```

Incrementing of the access_denied_errors Status Variable

The access_denied_errors status variable is incremented when someone tries to access something they do not have rights to.

This happens in the following cases:

- When accessing a database, table, or column that the user does not have rights to access. The error is sent to the client.
- When a login fails because of the wrong user/password, etc. The error is printed to the general log.
- When the require_secure_transport option is enabled on the server, and the user has not used a secure transport. The error is sent to the client.
- Users try to change to a database/schema they do not have access to. A warning is written to the error log if log_warnings > 1.
- Users try to use a `SHOW` command to access an object they do not have rights to see. The error is sent to the client.
- Users access something that requires global access, like “CREATE SERVER”. The error is sent to the client.

Login failures can be found in the general log. Errors that are sent to the client can be found by using the SQL Error Log Plugin. The plugin captures all errors sent to the client. Starting from MariaDB 10.11.5, it can also optionally capture all warnings sent to the client.

User Password Expiry

Password expiry permits administrators to expire user passwords, either manually or automatically.

System Variables

There are two system variables which affect password expiry: default_password_lifetime, which determines the amount of time between requiring the user to change their password. `0`, the default, means automatic password expiry is not active.

The second variable, disconnect_on_expired_password determines whether a client is permitted to connect if their password has expired, or whether they are permitted to connect in sandbox mode, able to perform a limited subset of queries related to resetting the password, in particular SET PASSWORD and SET.

Setting a Password Expiry Limit for a User

Besides automatic password expiry, as determined by default_password_lifetime, password expiry times can be set on an individual user basis, overriding the global using the CREATE USER or ALTER USER statements, for example:

```
CREATE USER 'monty'@'localhost' PASSWORD EXPIRE INTERVAL 120 DAY;
```

```
ALTER USER 'monty'@'localhost' PASSWORD EXPIRE INTERVAL 120 DAY;
```

Limits can be disabled by use of the `NEVER` keyword, for example:

```
CREATE USER 'monty'@'localhost' PASSWORD EXPIRE NEVER;
```

```
ALTER USER 'monty'@'localhost' PASSWORD EXPIRE NEVER;
```

A manually set limit can be restored the system default by use of `DEFAULT`, for example:

```
CREATE USER 'monty'@'localhost' PASSWORD EXPIRE DEFAULT;
```

```
ALTER USER 'monty'@'localhost' PASSWORD EXPIRE DEFAULT;
```

Note that the limit is defined as the number of days since the last password change. And the last password change is the value of `CURRENT_TIMESTAMP` when the password was changed last. If the `@@secure_timestamp` variable is set to NO (which is its default value) any user can modify the session timestamp arbitrarily, in particular, they can pretend that the password was changed at some point in time far in the future, effectively disabling any password expiration limit.
To prevent it you need to make sure the `@@secure_timestamp` is set or to audit password expiration limits regularly.

SHOW CREATE USER

The SHOW CREATE USER statement will display information about the password expiry status of the user. Unlike MySQL, it will not display if the user is unlocked, or if the password expiry is set to default.

```
CREATE USER 'monty'@'localhost' PASSWORD EXPIRE INTERVAL 120 DAY;
CREATE USER 'konstantin'@'localhost' PASSWORD EXPIRE NEVER;
CREATE USER 'amse'@'localhost' PASSWORD EXPIRE DEFAULT;

SHOW CREATE USER 'monty'@'localhost';
+-----------------------------------------------------------------------+
| CREATE USER for monty@localhost                                       |
+-----------------------------------------------------------------------+
| CREATE USER 'monty'@'localhost' PASSWORD EXPIRE INTERVAL 120 DAY |
+-----------------------------------------------------------------------+

SHOW CREATE USER 'konstantin'@'localhost';
+-------------------------------------------------------------+
| CREATE USER for konstantin@localhost                        |
+-------------------------------------------------------------+
| CREATE USER 'konstantin'@'localhost' PASSWORD EXPIRE NEVER |
+-------------------------------------------------------------+

SHOW CREATE USER 'amse'@'localhost';
+--------------------------------+
| CREATE USER for amse@localhost |
+--------------------------------+
| CREATE USER 'amse'@'localhost' |
+--------------------------------+
```

Checking When Passwords Expire

MariaDB starting with 11.5

From MariaDB 11.5, the Information Schema USERS table stores password expiry and password error information. An unprivileged user can access their own user data from the table.

The following query can also be used to check when the current passwords expire for all users:

```
WITH password_expiration_info AS (
  SELECT User, Host,
  IF(
   IFNULL(JSON_EXTRACT(Priv, '$.password_lifetime'), -1) = -1,
   @@global.default_password_lifetime,
   JSON_EXTRACT(Priv, '$.password_lifetime')
  ) AS password_lifetime,
  JSON_EXTRACT(Priv, '$.password_last_changed') AS password_last_changed
  FROM mysql.global_priv
)
SELECT pei.User, pei.Host,
  pei.password_lifetime,
  FROM_UNIXTIME(pei.password_last_changed) AS password_last_changed_datetime,
  FROM_UNIXTIME(
   pei.password_last_changed +
   (pei.password_lifetime * 60 * 60 * 24)
  ) AS password_expiration_datetime
  FROM password_expiration_info pei
  WHERE pei.password_lifetime != 0
   AND pei.password_last_changed IS NOT NULL
UNION
SELECT pei.User, pei.Host,
  pei.password_lifetime,
  FROM_UNIXTIME(pei.password_last_changed) AS password_last_changed_datetime,
  0 AS password_expiration_datetime
  FROM password_expiration_info pei
  WHERE pei.password_lifetime = 0
   OR pei.password_last_changed IS NULL;
```

–connect-expired-password Client Option

The mariadb client `--connect-expired-password` option notifies the server that the client is prepared to handle expired password sandbox mode (even if the `--batch` option was specified).

Catalogs

> **Note:**
>
> Catalogs are planned for an upcoming release, and don't yet appear in any current releases.

Catalogs are a user account management feature. This section explains their role in organizing database objects and controlling access permissions.

See Catalogs Overview.

Introduces MariaDB catalogs, a multi-tenancy feature that lets a single server host multiple independent tenants, each with their own users, schemas, and logs.

See Starting with Catalogs.

Guide to initializing a MariaDB server with catalog support using `mariadb-install-db --catalogs` and adding new catalogs to a running instance.

See Catalog-Specific Functions and Variables.

Documents the catalog() function, which returns the current catalog name, and the @@catalogs system variable, which indicates if the server is configured for catalogs.

See Catalog Status Variables.

Covers status variables related to catalog operations and performance, useful for monitoring multi-tenant environments.

See Connecting to a Server Configured for Catalogs.

Explains how to connect to a specific catalog using the –catalog client option or the catalog_name.database_name syntax.

See CREATE CATALOG.

Define external catalogs for data integration. This statement configures connections to remote storage systems, allowing query access to external data sources.

See SHOW CREATE CATALOG.

Reference for the SHOW CREATE CATALOG statement, which displays the SQL statement used to create a specific catalog.

See SHOW CATALOGS.

Reference for the SHOW CATALOGS statement, which lists all available catalogs on the server.

See USE CATALOG.

Reference for the USE CATALOG statement, allowing a user to switch their current session's context to a different catalog.

See DROP CATALOG.

Reference for the DROP CATALOG statement, used to remove a catalog and all its associated databases and users.

Catalogs Overview

> **Note:**
>
> Catalogs are planned for an upcoming release, and don't yet appear in any current releases.

MariaDB catalogs will be a multi-tenancy feature where a single instance MariaDB server handles multiple independent tenants (customers), who have their own users, schemas etc.
See MDEV-31542 "Add multi-tenancy catalogs to MariaDB" for details.

Background

For hosting providers, a common solution, to drive down cost, is to have one MariaDB server support several different customers by creating one named schema for each of them.

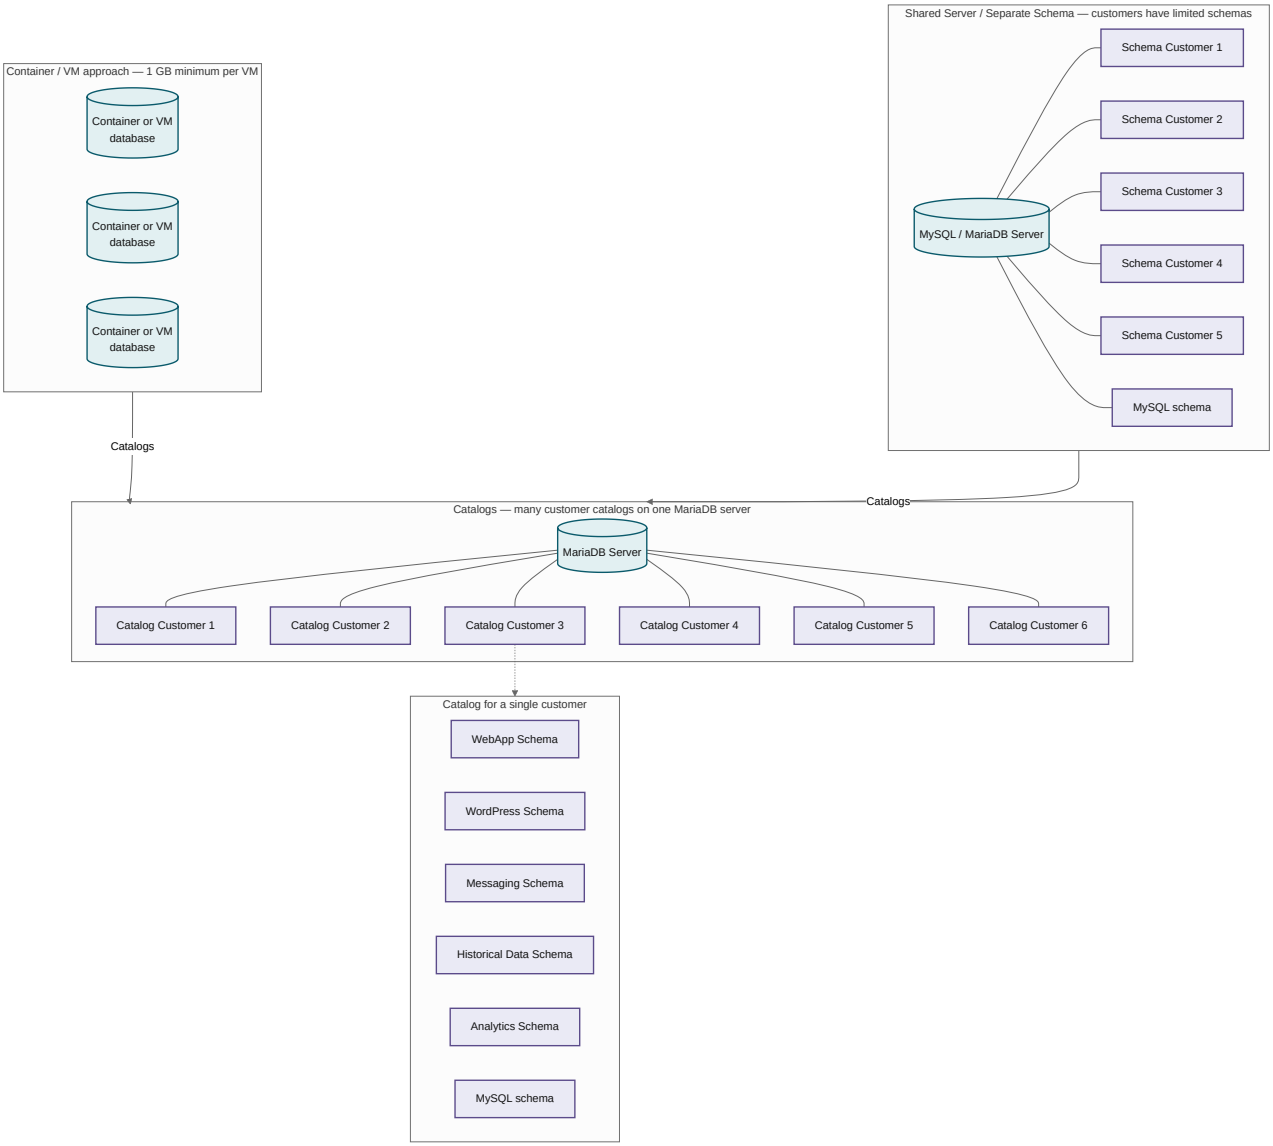
This has however a lot of limitations:

- The user cannot have exactly the same schema(s) on the cloud as they have on premise.
- The user cannot use multiple schemas.
- The user cannot take a backup of all their data (not even with mariadb-dump). This is because the 'mysql' schema, which includes users, stored procedures etc. cannot be copied as its data is shared among all server users.
- The user cannot access the general or error log.

The other option is to have a MariaDB container for each tenant. The problem with this is that, because of the memory needed per container, one can only have a very limited number of tenants per computer.

The suggested solution is to solve all of the above and thus create a better multi-tenant database is to add support for catalogs to MariaDB.

The following picture shows the change:



Moving to catalogs: instead of one VM or one schema per customer, a single MariaDB server hosts many customer catalogs, and each catalog holds all of that customer's schemas.

By each user having their own catalog, they will get very close to the same user experience as if they would have the MariaDB server for themselves.

Catalogs make it possible for hosting providers to have 10-100x more 'not that active' database users on a server compared to having a container or MariaDB server per customer (which limits a 192G server to about 100 customers with a 1G InnoDB buffer each).

User Experience With Catalogs

- Each user is assigned one catalog. The user can specify their catalog in their my.cnf file or as an argument to clients or when connecting to MariaDB server.
- Users can mariadb-dump of all their tables (including the 'mysql' database) and apply it on their own on premise MariaDB or to another 'MariaDB catalog' to duplicate their setup.
- Each catalog has its own privilege system. This allows a MariaDB admin to create users independently in their catalog to users in any other catalog. This also implies that the catalog has to be part of the connect information as otherwise the server does not know which user table to use.

- If the user is using applications that don't yet support catalogs, they can specify the catalog as part of the database when connecting to the server ('catalog.database') or by connecting to a specific port that is associated with a catalog.
- After logging in, a normal user can only see the objects (databases, tables, users etc) from their database. They cannot access other catalogs or change catalogs.
- A normal user cannot change the active catalog with a command. They need to logout from the current catalog and login to another.

For the end user, the MariaDB server will act as a normal a standalone server, with the following differences:

- When connecting to the server, a normal user must specify the catalog. If the connector software does not support catalogs, then the catalog should be specified in the database string. If the catalog is not specified, the 'def' catalog is assumed.
- LOAD DATA INFILE and SELECT … INTO OUTFILE can be configured to only be used with the catalog directory or a directory in it.
- SHUTDOWN command is only for the 'catalog root users'
- Replication (MASTER and SLAVE commands) are only for 'catalog root users'
- Errors from background task (like write error) will be logged into the system error log, not the catalog error log.
- SHOW STATUS will show status data for the whole server, not only for the active catalog.
- The server will handle legacy applications by extending the default database in the connection to contain the catalog in the form "catalog/database". See Appendix for details.
- Tables that are only read from the 'def.mysql' schema:
  - plugin
  - help_* tables
  - time_zone* tables
  - gtid_slave_pos (replication state)
  - innodb_index_stats (innodb internal)
  - servers (federated)
  - transaction_registry (innodb internal)
  - func (udf)
  - performance_schema

New 'catalog root user'

- The 'def' catalog is reserved to store permissions for 'catalog root users', which can access any catalog. * These are meant for admin users that need to do tasks like shutdown, upgrade, create/drop catalogs, managing primaries and replicas etc.
- Only the 'catalog root user' can change to another catalog with 'set catalog catalog_name'.
- A normal user can do 'set catalog current-catalog'. This will be needed to be able to execute a mariadb-dump that includes this command.

New Storage Layout

MariaDB server will be able to run either on 'original mode', where the data layout is exactly as it was before, or on 'catalog' mode, with a new data layout:

When running mariadb-install-db with –use-catalogs, it will create the following new data structure:

- data_directory/
  - engine system data files
  - system files

    - replication files
    - general.log
    - error.log
    - mariadb/
        - mysql/
        - privilege tables
    - catalog1
    - general.log
    - error.log
    - mysql/
        - privilege tables
    - database1/
        - tables for database1
    - database2/
        - tables for database2
    - catalog2/
        - general.log
        - error.log
    - mysql/
        - privilege tables
    - database1/
        - tables for database1
    - database2/
        - tables for database2

The disk structure when not using catalogs is:

- data_directory/
    - engine system data files
    - system files
    - replication files
    - general.log
    - error.log
    - mysql/
        - privilege tables
    - database1/
        - tables for database1
    - database2/
        - tables for database2

The above shows:

- There is a ‘mariadb’ catalog that stores admin users that can access all catalogs, shutdown servers, create new catalogs etc. The ‘system root’ user uses this when connecting.
- Each catalog has their own users, privilege tables, databases, error log and general logs

The MariaDB server will automatically start in catalog mode if it notices the new directory structure.

Catalog SQL Commands/Functions

- USE CATALOG catalog_name;
- CREATE CATALOG
- DROP CATALOG
- ALTER CATALOG
- SHOW CATALOGS (and also information_schema.catalogs)
- SHOW CREATE CATALOG catalog_name;
- SELECT CATALOG();

Changes Needed in MariaDB Codebase

Client changes:

- Add –catalog option to all standard MariaDB clients
- Add support for looping over all existing catalogs to:
  - mariadb-dump
  - mariadb-backup
  - mariadb-upgrade

Changes to mariadb-install-db:

- Allow one to create multiple catalogs at once: -–catalogs=”catalog1,catalog2”
- Init MariaDB with catalog support: —use-catalogs

Changes to mariadb (mysql client):

- Add support for ‘USE CATALOG xxx’’ (and later ‘use database xxx’).

Changes to mysql-test-run:

- Add support of running tests with catalogs (normal tests are run without catalogs)

Changes to MariaDB server (See MDEV-31542):

- Add support for ‘catalog’ in the connection string. For old clients, the user can specify the catalog as part of the database. If catalog is not specified, the ‘def’ catalog (like now) is assumed.
- Add CATALOG() function that returns the current catalog.
- Add ‘USE CATALOG xxx’
- Add ‘USE DATABASE xxx’
- Create a global CATALOG object to hold all information related to the catalog.
- Add the current catalog to the ‘thd’ object.
- Add catalog argument to all functions that take ‘database’ as an argument.
- Add SHOW CATALOGS and information_schema.catalogs
- Move all relevant global variables (users, privileges, mdl-locks(?), open log files) to be stored in the CATALOG structure.
- Add ‘catalog privilege’, for ‘catalog super users’ to allow them to access data in any catalog.
- Add support for accessing tables with ‘catalog.schema.table’ (needed for catalog super users).
- For normal users, only show processes for the current catalog in ‘show processlist’.
- Add loops over all catalogs for information schema for the ‘catalog root user’.
- Update performance schema to take catalogs into account.
- Work with external connectors to get them to support connecting with a catalog.
- Check/update all storage engines to ensure they work also with catalogs.

Notes:

- The storage handler calls will probably not be changed. The storage engine will get the catalog name as part of the database name (catalog/database).
- We don't need a 'catalog' column for tables in the 'mysql' schema (like mysql.proc) as these are stored per catalog.

Some Implementation Ideas

- Instead of sending a catalog string to function, use a pointer to the global catalog object. Do the same later for databases. This allows use to precompute things like 'filename' for catalogs and databases and we don't have to do this for every table open. It also allows us to later support logging information at a catalog and database level.
- Don't take a MDL lock for the catalog for each table. The metadata lock for the catalog will be taken when a user logs in or changes catalog.
- Add system variables 'current_catalog' and 'current_database' and allow users to change these.
- Add support for 'catalog ports' that are connected to catalog. This allows users to connect to a specific catalog from any client software.

Limitations (in addition to limitations listed in "User experience with catalogs")

- Database names cannot contain '.' when connecting from clients without the new catalog connect option.
- One cannot refer to other catalogs in triggers, stored procedures, events etc. This is because a transaction cannot span catalogs.
- Only the catalog root user can use mariadb-backup. This is a normal restriction as one has to be system root to be able to use mariadb-backup.
- Events are global (to save resources). Catalog users can enable/disable events for their catalog.

Stage 2 (not in first release)

- Support usage statistics per catalog and whole server (the last for the 'catalog root user'). This allows the DBA to see the number of queries, type of queries etc. Some 'system' and 'global innodb' statistics will only be shown globally (number of open files, number of sync calls etc).
- Support a my.cnf file in each catalog directory to handle catalog (customer) unique defaults.
- Add quotas per catalog for tables and temporary files.
- Add more support to limit users from overusing resources (cpu, tables, databases, number of connections etc)
- Support 'drop catalog'. (This is in Stage 2 as there may be some issues to drop already active CATALOG objects)
- Add optional catalog support to the S3 engine
- More things will be added later.

Stage 3

- Allow users to manage their own replication stream (maybe?).
- Allow users to have different options for the S3 engine
- More things will be added later.

Appendix

Legacy Connector Support

SQLALchemy test:

```
In [1]: from sqlalchemy.engine import make_url
In [2]: u = make_url('mariadb+mariadbconnector://app_user:Password123!@127.0.0.1:3306/catalog/company')
In [3]: u.database
Out[3]: 'catalog/company'
```

The following tests ensured that inside the server (mysql_change_db), the “catalog/test” was picked up as the database.

PHP PDO test:

```
$ php -r '$db = new
\PDO("mysql:host=localhost;user=dan;dbname=catalog/test;charset=utf8mb4;unix_socket=/tmp/build-mariadb-
server-10.4.sock");'
```

PHP mysqli test:

```
php -r '$dbcon = mysqli_connect("localhost","dan","nopass","catalog/test",3306,"/tmp/build-mariadb-
server-10.4.sock");'
```

Nodejs test:

```
var mysql = require('mysql')
var con = mysql.createConnection({
  socketPath: "/tmp/build-mariadb-server-10.4.sock",
  user: "dan",
  password: "yourpassword",
  database: "catalog/test",
})
con.connect(function(err) {
  if (err) throw err;
  console.log("Connected!");
})
```

(need to map out a few other connectors here to make sure it’s supported well in this form).

Ref: connection.md#handshake-response-packet

Migration of Existing MariaDB Original Mode to the New Catalog Layout

As shared hosting services have a naming scheme from user/schema to database name in MariaDB, to provide a migration to the new catalog layout, the following steps will be required:

- Use mariadb-dump to dump the original data
- On the new server execute:
- mariadb-install-db –catalogs=’catalog_name’
- mariadb –catalog catalog_name < dump_file

This is needed as InnoDB needs to know where the new files are located.

Migration of One Catalog User to Another MariaDB Server

Create a migration tool set / procedure that does the following

- Execute FLUSH TABLES FOR EXPORT for all tables in a catalog.
- Take a copy of the catalog directory
- Copy the data to a new catalog directory to the new server
- Run ALTER TABLE … IMPORT TABLESPACE on each InnoDB table

Note that for partitioned tables the process will be a bit more complex, see above link.

This procedure will be a bit easier after an in-the-works patch for InnoDB related to IMPORT will be pushed. (Should happen before we start on the catalog project)

Other Things

- Drizzle's default catalog was called "local". MariaDB's default will be called 'def', as this is what we already have as the default catalog in information_schema, in current connectors and other places.
- CONNECT engine will need testing against catalogs and maybe a small code change to support them. It could also be a way to join from one catalog to another.

This page is licensed: CC BY-SA / Gnu FDL

Starting with Catalogs

> **Note:**
>
> Catalogs are planned for an upcoming release, and don't yet appear in any current releases.

Background

mariadb-install-db initializes the MariaDB data directory and creates the system tables in the mysql database.

When used with the `--catalog` options it will initialize MariaDB server to use catalogs.
The mariadbd server will automatically discover if catalogs are used or not.

Note that **one cannot change** a 'normal server' to a server with catalogs or a server with catalogs to a 'normal server'. In the future we will add tools that will allow one to easily move an existing server inside a catalog or move an server inside a catalog to a standalone server.

Initializing a New Server with Catalog Support

To initialize a server with 4 catalogs (the `def` catalog, that holds the catalog root user (CRU) is automatically created):

```
mariadb_install_db --catalogs="cat1 cat2 cat3" --datadir=/my/data/
```

The above will create a directory `/my/data` and the 4 directories under it, one for each catalog.

Adding More Catalogs to a Running Server

Creating Catalogs with CREATE CATALOG

One can create a new catalog with CREATE CATALOG catalog_name

Creating Catalogs with mariadb_install_db

When adding more catalogs to an existing server, `mariadb_install_db` will start the mariadb client to execute the needed commands on the running server. This is why one has to supply user and password to `mariadb_install_db`.

```
mariadb_install_db --catalogs="cat4 cat5 cat6" --datadir=/my/data --catalog-user=monty --catalog-password
```

One benefit of using `mariadb_install_db` is that it's possible to create many catalogs with one command.

Catalog-Specific Functions and Variables

> **Note:**
>
> Catalogs are planned for an upcoming release, and don't yet appear in any current releases.

Catalog Functions

catalog()

`catalog()

returns the name of the current catalog.`

```
MariaDB [def.test]> select catalog();
+-----------+
| catalog() |
+-----------+
| def       |
+-----------+
```

Catalog Variables

@@catalogs

One can check if a server supports catalogs with:

```
SELECT @@catalogs;
+------------+
| @@catalogs |
+------------+
|          1 |
+------------+
```

1 means that the server is configured for catalogs.

This page is licensed: CC BY-SA / Gnu FDL

Catalog Status Variables

> **Note:**
>
> Catalogs are planned for an upcoming release, and don't yet appear in any current releases.

When using a MariaDB Server with catalogs support, all status information is collected for the whole server, per catalog and per session.

```
SHOW SERVER STATUS;
```

shows the status for the whole server. Note that only the super user in the 'def' catalog has privileges for the above statement.

```
SHOW GLOBAL STATUS;
SHOW CATALOG STATUS;
```

Both commands show the status for the current catalog.
The reason that `GLOBAL` shows catalog status is that because catalogs are 'multi-tenant', a catalog user should not be able to see the status from other users (for most things).

```
SHOW [SESSION] STATUS;
```

Shows the status for the current connection.

The main "new thing" is that catalogs enable SAS providers to see the status for a single tenant (catalog user). This makes it much easier to find 'bad neighbors' (tenants that cause problems for other tenants) so that they can be moved to other servers.

When the MariaDB server is not configured for catalogs, the following commands are equivalent:

```
SHOW GLOBAL STATUS
SHOW SERVER STATUS
SHOW CATALOG STATUS
```

See Also

- SHOW STATUS

Connecting to a Server Configured for Catalogs

> **Note:**
>
> Catalogs are planned for an upcoming release, and don't yet appear in any current releases.

When connecting to a MariaDB server configured for catalogs, one has to provide the catalog to connect to. There are several ways to do this:

All new native MariaDB clients will support the `--catalog` option:

```
mariadb --catalog=mine test
```

New and old clients can use the 'catalog_name.database_name' syntax to connect:

```
mariadb mine.test
```

This will connect the user to the 'mine' catalog and the database 'test'.

Note that one consequence of this is that one should not have a database that contains '.' in the name. If such a database exists, one can still connect to it by using the `--catalog=` option or prefixing the database with the catalog, like in `def.data.base.name`.

One will also be able to configure the MariaDB server to automatically choose catalogs depending on the port or IP they are using to connect to the server. This is done by adding the following to the catalog specific my.cnf file, residing in the catalog directory:

```
[[mariadbd]]
--port=#
--connect-ip=
```

If catalogs is not specified either directly (—catalog=#) or indirectly (with port or ip) the catalog `def` will be used.

When connecting to a server not configured for catalogs, one can still use `mariadb --catalog=def` or `mariadb def.datbase_name`.

To check if a server supports catalogs:

```
SELECT @@catalogs;
+------------+
| @@catalogs |
+------------+
|          0 |
+------------+
USE catalog foo;
ERROR 4193 (HY000): MariaDB is not configured to support catalogs
```

0 means that the server is not configured for catalogs.

This page is licensed: CC BY-SA / Gnu FDL

CREATE CATALOG

> **Note:**
>
> Catalogs are planned for an upcoming release, and don't yet appear in any current releases.

Syntax

```
CREATE CATALOG [IF NOT EXISTS] catalog_name
    [create_specification] ...

create_specification:
    [DEFAULT] CHARACTER SET [=] charset_name
  | [DEFAULT] COLLATE [=] collation_name
  | COMMENT [=] 'comment'
```

Description

Creates a catalog and the `mysql`, `sys` and `performance_schema` schemas inside the catalog.

`CREATE CATALOG` can only be performed by a user in the `def` catalog with the CATALOG privilege.

Note that no users are created.

Example

```
CREATE CATALOG cat1;
USE CATALOG cat1;
CREATE USER root@localhost;
GRANT ALL PRIVILEGES ON *.* TO root@localhost;
CREATE DATABASE test;
```

Limitations

The catalog name is limited to 64 characters. All characters must be in the basic ASCII set:
(A-Z, a-z, -, _)
This limitations is to be able to run catalogs with engines like InnoDB which has limited space in their internal data dictionary.

Pre-Creating Catalog Directories

`CREATE CATALOG` works even if the catalog directory already exists (as long as there is no `mysql` sub directory). This is to allow a database administrator to pre-create the catalog directory and mount it to disk volume and optionally add a configuration file inside the catalog directory.
The directory will not be recognized as a catalog or show up in SHOW CATALOGS until the `mysql` sub directory is created by CREATE CATALOG or mariadb-install-db.

See Also

- marriadb-install-db can be used to create multiple catalogs with a default root user in one go.
- DROP CATALOG

This page is licensed: CC BY-SA / Gnu FDL

SHOW CREATE CATALOG

> **Note:**
>
> Catalogs are planned for an upcoming release, and don't yet appear in any current releases.

Syntax

```
SHOW CREATE CATALOG catalog_name
```

Description

Shows the CREATE CATALOG statement that creates the given catalog.

Examples

```
SHOW CREATE CATALOG def;
+---------+-----------------------------------------------------------------------------------------------
---------+
| Catalog | Create Catalog
|
+---------+-----------------------------------------------------------------------------------------------
---------+
| def     | CREATE CATALOG `def` DEFAULT CHARACTER SET latin1 COLLATE latin1_swedish_ci COMMENT 'default
catalog' |
+---------+-----------------------------------------------------------------------------------------------
---------+
```

SHOW CATALOGS

> **Note:**
>
> Catalogs are planned for an upcoming release, and don't yet appear in any current releases.

Syntax

```
SHOW CATALOGS
    [LIKE 'pattern' | WHERE expr]
```

Description

`SHOW CATALOGS` lists the catalogs on the MariaDB server host.
The `LIKE` clause, if present on its own, indicates which catalog names to match. The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in Extended SHOW.

You see only use `SHOW CATALOGS` have the CATALOG privilege. Only users of the 'def' schema can have this privilege.

If the server was started with the –skip-show-database option, you cannot use this statement unless you have the SHOW DATABASES privilege.

The list of results returned by `SHOW CATALOGS` is based on directories in the data directory, which is how MariaDB implements catalogs. It only list directories that have a `mysql` directory.

The Information Schema Catalogs table also contains catalog information.

Examples

```
+---------+--------------------+
| Catalog | Comment            |
+---------+--------------------+
| c1      | This is catalog c1 |
| cat2    |                    |
| def     | default catalog    |
+---------+--------------------+
```

```
SHOW CATALOGS LIKE 'c%';
+--------------+--------------------+
| Catalog (c%) | Comment            |
+--------------+--------------------+
| c1           | This is catalog c1 |
| cat2         |                    |
+--------------+--------------------+
```

USE CATALOG

> **Note:**
>
> Catalogs are planned for an upcoming release, and don't yet appear in any current releases.

Syntax

```
USE CATALOG catalog_name
```

Description

Changes to another catalog.
Can only be done by a super user in the ‘def’ catalog.
Changing catalog will update catalog status and reset all session status.

A tenant (a user in any other catalog than ‘def’) cannot change to another catalog.
However tenants can execute `USE CATALOG current_catalog`. This is to allow the user to import SQL scripts that use `USE CATALOG...`.

See Also

- USE database. Changing database.

This page is licensed: CC BY-SA / Gnu FDL

DROP CATALOG

> **Note:**
>
> Catalogs are planned for an upcoming release, and don’t yet appear in any current releases.

Syntax

```
DROP CATALOG catalog_name
```

Description

Deletes a catalog.

Limitations:

- `DROP CATALOG` can only be performed by a super user in the ‘def’ catalog.
- The current catalog cannot be dropped.
- The ‘def’ catalog cannot be dropped.

When dropping a catalog, all databases and files within that catalog will be deleted.

Authentication with Enterprise Server

See Authentication for MariaDB Enterprise Server.

Overview of user account authentication using plugins like pam or unix_socket and managing security with password validation plugins.

See Authentication with gssapi.

Instructions for installing and configuring the gssapi plugin to validate user credentials against services like Kerberos or NTLM.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Authentication for MariaDB Enterprise Server

Overview

MariaDB Enterprise Server authentication is performed by database user accounts. Database user accounts are specified by user name, the hostname from which the account is connecting, and the authentication plugins configured for the account, such as mysql_native_password, pam, or unix_socket.

Change Password

The password for a database user account can be changed using the ALTER TABLE, ALTER USER, and SET PASSWORD statements.

```
WITH ALTER USER:

ALTER USER 'USER'@'192.0.2.%'
   IDENTIFIED BY 'PASSWD';
```

```
WITH SET PASSWORD:

SET PASSWORD FOR 'USER'@'192.0.2.%'
   = PASSWORD('PASSWD');
```

Password Validation Plugins

If your MariaDB Enterprise Server node has a password validation plugin installed, then the password should also meet the configured requirements. When you try to set or change a user's password and the password validation plugin rejects the password, the following error message will be shown:

```
ERROR HY000: Your password does not satisfy the current policy requirements.
```

By default, the MariaDB Enterprise Server installs the simple_password_check plugin, but the cracklib_password_check plugin is also available.

For simple_password_check, the password requirements are configured by several system variables:

- simple_password_check_digits
- imple_password_check_letters_same_case
- simple_password_check_minimal_length
- simple_password_check_other_characters

Authentication Plugins

MariaDB Enterprise Server uses authentication plugins to support different authentication methods. The default authentication plugin is mysql_native_password.

- Authentication with ed25519
- Authentication with gssapi
- Authentication with mysql_native_password
- Authentication with mysql_old_password
- Authentication with pam
- Authentication with unix_socket
- Authentication with PARSEC

This page is: Copyright © 2026 MariaDB. All rights reserved.

Authentication with gssapi

Overview

The gssapi authentication plugin validates user credentials against a GSSAPI-based authentication service, like Kerberos or NTLM.

Install Package

The gssapi authentication plugin requires an additional package to be installed on Linux.
On CentOS, RHEL, and Rocky Linux:

```
$ sudo yum install MariaDB-gssapi-server
```

On Debian and Ubuntu:

```
$ sudo apt install mariadb-plugin-gssapi-server
```

On SLES:

```
$ sudo zypper install MariaDB-gssapi-server
```

Configure

The gssapi authentication plugin requires some system variables to be configured, including:

- gssapi_keytab_path
- gssapi_principal_name

For example:

```
[mariadb]
...
gssapi_keytab_path=KEYTAB_PATH
gssapi_principal_name=PRINCIPAL_NAME
```

Install Plugin

The gssapi authentication plugin must be installed before it can be used.

To install with the INSTALL SONAME statement:

```
INSTALL SONAME 'gssapi';
```

To install in a configuration file with the plugin_load_add option:

```
[mariadb]
...
plugin_load_add = auth_gssapi
```

Create User

To create a user account that uses the gssapi authentication plugin, specify the plugin in the CREATE USER statement:

```
CREATE USER 'USER'@'192.0.2.%'
   IDENTIFIED VIA gssapi;
```

An optional realm can be specified:

```
CREATE USER 'USER'@'192.0.2.%'
   IDENTIFIED VIA gssapi USING 'USER@DOMAIN';
```

Limiting Size of Created Disk Temporary Files and Tables

See Limiting Size of Created Disk Temporary Files and Tables Overview.

Overview of the feature introduced in MariaDB 11.5 to limit disk space used by temporary files and internal on-disk temporary tables to prevent disk exhaustion.

See max_tmp_session_space_usage System Variable.

Documentation for the system variable that restricts the maximum total size of temporary files and tables allowed for an individual user session.

See max_tmp_total_space_usage System Variable.

Reference for the global system variable that defines the maximum cumulative disk space all user connections can consume for temporary files and tables.

This page is licensed: CC BY-SA / Gnu FDL

Limiting Size of Created Disk Temporary Files and Tables Overview

> **Note:**
>
> This functionality is available from MariaDB 11.5.

You can limit the size of created disk temporary files and tables.
When the internal in-memory temporary table is oversize and converting to MyISAM/Aria table to store on disk, this option will limit the max space of tmp_dir. If a new disk temporary table will cause tmp_dir over the limitation, then this query will return an error.

Temporary Space

The temporary space includes:

- All SQL level temporary files. This includes files for filesort, transaction temporary space, analyze, binlog_stmt_cache etc. It does not include engine internal temporary files used for repair, alter table, index pre sorting etc.
- All internal on disk temporary tables created as part of resolving a SELECT, multi-source update etc.

Special Cases

- When doing a commit, the last flush of the binlog_stmt_cache will not cause an error even if the temporary space limit is exceeded. This is to avoid giving errors on commit. This means that a user can temporary go over the limit with up to binlog_stmt_cache_size.

System Variables

There are two system variables used for controlling this feature:

- max_tmp_session_space_usage: Limits the temporary space allowance per user
- max_tmp_total_space_usage: Limits the temporary space allowance for all users.

Status Variables

- tmp_space_used
- max_tmp_space_used

Information Schema

- New field in information_schema.process_list: TMP_SPACE_USED

Noteworthy issue

- One has to be careful when using small values for max_tmp_space limit together with binary logging and with non transactional tables.
- If a binary log entry for the query is larger than binlog_stmt_cache_size and one hits the limit of max_tmp_space when flushing the entry to disk, the query will abort and the binary log will not contain the last changes to the table. This will also stop the replica!
- This is also true for all Aria tables as Aria cannot do rollback (except in case of crashes)!
- One way to avoid it is to use @@binlog_format=statement for queries that update many lot of rows.

Implementation

- All writes to temporary files or internal temporary tables, that increase the file size, are routed through temp_file_size_cb_func() which updates and checks the temp space usage.
- Most of the temporary file monitoring is done inside IO_CACHE. Temporary file monitoring is done inside the Aria engine.
- MY_TRACK and MY_TRACK_WITH_LIMIT are new flags for ini_io_cache(). MY_TRACK means that we track the file usage. TRACK_WITH_LIMIT means that we track the file usage and we give an error if the limit is breached. This is used to not give an error on commit when binlog_stmt_cache is flushed.
- global_tmp_space_used contains the total tmp space used so far. This is needed quickly check against max_total_tmp_space_usage.
- Temporary space errors are using EE_LOCAL_TMP_SPACE_FULL and handler errors are using HA_ERR_LOCAL_TMP_SPACE_FULL. This is needed until we move general errors to it's own error space so that they cannot conflict with system error numbers.
- Return value of my_chsize() and mysql_file_chsize() has changed so that -1 is returned in the case my_chsize() could not decrease the file size (very unlikely and will not happen on modern systems). All calls to _chsize() are updated to check for > 0 as the error condition.
- At the destruction of THD we check that THD::tmp_file_space == 0
- At server end we check that global_tmp_space_used == 0
- As a precaution against errors in the tmp_space_used code, one can set max_tmp_space_usage and max_total_tmp_space_usage to 0 to disable the tmp space quota errors.
- truncate_io_cache() function added.
- Aria tables using static or dynamic row length are registered in 8K increments to avoid some calls to update_tmp_file_size().

max_tmp_session_space_usage System Variable

`max_tmp_session_space_usage`

- Description: The maximum total size of temporary file and temporary table usage. A value of 0 disables this feature. Set in blocks of 65536, rounded down if not a multiple of 65536. See Limiting Size of Created Disk Temporary Files and Tables Overview for details. Named max_tmp_space_usage in MariaDB 11.5.0 only.
- Commandline: `--max-tmp-session-space-usage=num`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric` (bigint unsigned)
- Default Value: `1099511627776`
- Range: `0` to `18446744073709551615` (blocks of `65536`)
- Introduced: MariaDB 11.5

This page is licensed: CC BY-SA / Gnu FDL

max_tmp_total_space_usage System Variable

`max_tmp_total_space_usage`

- Description: The maximum total size in bytes of all temporary file and temporary table usage over all connections. A value of 0 disables this feature. Set in blocks of 65536, rounded down if not a multiple of 65536. See Limiting Size of Created Disk Temporary Files and Tables Overview for details. Called max_total_tmp_space_usage in MariaDB 11.5.0 only.
- Commandline: `--max-tmp-total-space-usage=num`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric` (bigint unsigned)
- Default Value: `1099511627776`
- Range: `0` to `18446744073709551615` (blocks of `65536`)
- Introduced: MariaDB 11.5

Security Vulnerabilities (CVE) Fixed in MariaDB

> **Note:**
>
> This page is about security vulnerabilities fixed in MariaDB products. If you are looking for information on securing your MariaDB installation, see Securing MariaDB.

> **Important:**
>
> Sensitive security issues can be reported on https://hackerone.com/mariadb or sent directly to the persons responsible for MariaDB security: security [AT] mariadb (dot) org.

What is a CVE?

Common Vulnerabilities and Exposures (CVE) relate to flaws “in a software, firmware, hardware, or service component resulting from a weakness that can be exploited, causing a negative impact to the confidentiality, integrity, or availability of an impacted component or components.”

It is a publicly available and free-to-use database of known software vulnerabilities maintained at https://cve.mitre.org/.

For additional information, see CVE Glossary at cve.org

What is a CVSS Score?

Common Vulnerability Scoring System (CVSS) is “an open framework for communicating the characteristics and severity of software vulnerabilities.”

For additional information, see Vulnerability Metrics at nvd.nist.gov

Fixed Security Vulnerabilities

See Security Vulnerabilities (CVE) Fixed in MariaDB Enterprise Server.

This page contains a full list of CVEs fixed in all versions and series of MariaDB Enterprise Server.

See Security Vulnerabilities (CVE) Fixed in MariaDB Community Server.

This page contains a full list of CVEs fixed in all versions and series of MariaDB Community Server.

Some CVE apply to MySQL but are not present in MariaDB Enterprise Server or MariaDB Community Server; these are listed on the Security Vulnerabilities fixed in Oracle MySQL that did not exist in MariaDB page.

This page is licensed: CC BY-SA / Gnu FDL

Security Vulnerabilities (CVE) Fixed in MariaDB Enterprise Server

The list is updated continuously. CVEs may be added retroactively to already-released versions, as vulnerabilities can be reported to and assigned by CVE Numbering Authorities (CNAs) after the corresponding fix has been released. As a result, a release may receive additional CVE entries over time even after it has been published.

Table of Fixed Security Vulnerabilities

CVE ID (with cve.org link)	CVE Published	CVSS base score (v3.1)	Enterprise Server Releases
CVE-2026-3494	2026-03-03	4.3	11.8.8-5 (2026-06-26), 11.4.12-9 (2026-06-26), 10.6.27-23 (2026-06-26)

#1:

MariaDB CVEs are assigned a word rating instead of a CVSS base score. See the MariaDB Engineering Policy for details.

What CVEs are listed on this page?

This page provides a cross-reference for all CVEs addressed through a release of MariaDB Enterprise Server.

Enterprise Server Benefits

MariaDB Enterprise Server is an enhanced, hardened, and secured product with:

- Enterprise-grade testing to drive a low defect rate
- Increased code stability through restricted release of new functionality
- Reduced risk from untested or incompatible features through inclusion of only features with level 3 support (Engineering code-level support) from MariaDB Corporation
- Optimized configuration defaults
- Premium features to meet enterprise scaling and operations requirements
- Documentation maintained by MariaDB Corporation

This page is: Copyright © 2026 MariaDB. All rights reserved.

Security Vulnerabilities (CVE) Fixed in MariaDB Community Server

The list is updated continuously. CVEs may be added retroactively to already-released versions, as vulnerabilities can be reported to and assigned by CVE Numbering Authorities (CNAs) after the corresponding fix has been released. As a result, a release may receive additional CVE entries over time even after it has been published.

Table of Fixed Security Vulnerabilities

CVE ID (with cve.org link)	CVE Published	CVSS base score (v3.1)	Community Server Releases
CVE-2026-49261	—	10.0	11.8.8 (2026-05-27), 11.4.12 (2026-05-27), 10.11.18 (2026-05-27), 10.6.27 (2026-05-27)
CVE-2026-48165	—	8.0	11.8.8 (2026-05-27), 11.4.12 (2026-05-27), 10.11.18 (2026-05-27), 10.6.27 (2026-05-27)
CVE-2026-48163	—	8.0	11.8.8 (2026-05-27), 11.4.12 (2026-05-27), 10.11.18 (2026-05-27), 10.6.27 (2026-05-27)
CVE-2026-44173	—	5.0	12.3.2 (2026-05-28), 11.8.7 (2026-05-18), 11.4.11 (2026-05-18), 10.11.17 (2026-05-18), 10.6.26 (2026-05-18)
CVE-2026-44172	—	5.0	12.3.2 (2026-05-28), 11.8.7 (2026-05-18), 11.4.11 (2026-05-18), 10.11.17 (2026-05-18), 10.6.26 (2026-05-18)
CVE-2026-44171	—	6.3	12.3.2 (2026-05-28), 11.8.7 (2026-05-18), 11.4.11 (2026-05-18), 10.11.17 (2026-05-18), 10.6.26 (2026-05-18)
CVE-2026-44170	—	5.0	12.3.2 (2026-05-28), 11.8.7 (2026-05-18), 11.4.11 (2026-05-18), 10.11.17 (2026-05-18), 10.6.26 (2026-05-18)
CVE-2026-44169	—	4.3	12.3.2 (2026-05-28), 11.8.7 (2026-05-18), 11.4.11 (2026-05-18)
CVE-2026-44168	—	8.0	12.3.2 (2026-05-28), 11.8.7 (2026-05-18), 11.4.11 (2026-05-18), 10.11.17 (2026-05-18), 10.6.26 (2026-05-18)
CVE-2026-3494	2026-03-03	4.3	12.2.2 (2026-02-12), 11.8.6 (2026-02-04), 11.4.10 (2026-02-04), 10.11.16 (2026-02-04), 10.6.25 (2026-02-04)
CVE-2026-32710	2026-03-20	8.6	12.2.2 (2026-02-12), 11.8.6 (2026-02-04), 11.4.10 (2026-02-04)
CVE-2026-35549	2026-04-03	6.5	12.2.2 (2026-02-12), 11.8.6 (2026-02-04), 11.4.10 (2026-02-04)
CVE-2026-34303	2026-04-21	6.5	12.2.2 (2026-02-12), 11.8.6 (2026-02-04), 11.4.10 (2026-02-04), 10.11.16 (2026-02-04)
CVE-2026-21968	2026-01-20	6.5	12.1.2 (2025-11-18), 11.8.4 (2025-11-06), 11.4.9 (2025-11-06), 10.11.15 (2025-11-06), 10.6.24 (2025-11-06)
CVE-2025-13699	2025-12-23	7.0	11.8.4 (2025-11-06), 11.4.9 (2025-11-06), 10.11.15 (2025-11-06), 10.6.24 (2025-11-06)

Security Vulnerabilities (CVE) Fixed in Oracle MySQL That Did Not Exist in MariaDB

About

CVE® stands for *Common Vulnerabilities and Exposures*. It is a publicly available and free-to-use database of known software vulnerabilities maintained at https://cve.mitre.org/.

CPU stands for *Critical Patch Update*. Oracle publishes Critical Patch Update Advisories four times a year, on the Tuesday closest to the 17th day of January, April, July and October. MySQL vulnerabilities are included in these CPU Advisories.

Some vulnerabilities found in MySQL apply to MariaDB as well, they are listed on the Security Vulnerabilities Fixed in MariaDB Enterprise Server and Security Vulnerabilities Fixed in MariaDB Community Server pages.

Other vulnerabilities found in MySQL do not apply to MariaDB.

This page lists all CVEs that were fixed in MySQL and mentioned in Oracle CPU Advisories, but that — *to the best of our knowledge* — were never present in MariaDB.

Architecture

MariaDB Server's architecture.

See Server Constraints.

Details the various constraints within MariaDB Server, including primary keys, unique keys, and foreign keys.

See Topologies.

Provides information on different MariaDB Server deployment topologies, including standalone, replication, and clustered configurations.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Topologies

See Topologies Overview.

MariaDB offers varied deployment topologies by workload and technology, each named and diagrammed with benefits listed. Custom configurations are also supported.

See Compatibility.

Operating-system support for MariaDB products and versions, with links to the engineering policies that list supported platforms.

See Columnstore Object Storage.

Deploy the MariaDB ColumnStore object-storage topology, a columnar OLAP store that keeps data on S3-compatible object storage.

See ColumnStore Shared Local Storage.

Deploy the MariaDB ColumnStore shared-local-storage topology, a columnar OLAP store for analytical workloads.

See Galera Cluster.

Deploy the Galera Cluster topology for MariaDB — synchronous, multi-primary replication for high availability.

See HTAP.

Deploy the HTAP topology, pairing MariaDB row storage with ColumnStore columnar storage for mixed transactional and analytical workloads.

See Installing Primary/Replica.

This page explains how to set up a standard Primary/Replica replication topology for MariaDB Enterprise Server.

See Single Node Topologies.

Install and configure single-node MariaDB deployments, including a single- node columnar store with optional S3-compatible object storage.

See Spider Storage Engine.

Scale MariaDB horizontally with the Spider storage engine, which shards tables across remote nodes through virtual federated tables.

See MariaDB Enterprise Spider Topologies.

Explore MariaDB Enterprise Spider topologies with MaxScale. This section details how it integrates with Spider to manage & route traffic efficiently across sharded & distributed database environments.

See Spider Federated.

Deploy Spider Federated Topology

See Spider Sharded.

Deploy Spider Sharded Topology

Topologies Overview

MariaDB products can be deployed in many different topologies. The topologies described in this section are representative. MariaDB products can be deployed to form other topologies, leverage advanced product capabilities, or combine the capabilities of multiple topologies.

Topologies are the arrangement of nodes and links to achieve a purpose. This documentation describes a few of the many topologies that can be deployed using MariaDB database products.

We group topologies by workload (transactional, analytical, hybrid) and technologies (Enterprise Spider). Single-node topologies are listed separately.

To help you select the correct topology:

- Each topology is named and this name is used consistently throughout the documentation.
- A thumbnail diagram provides a small-scale summary of the topology's architecture.
- Finally, we provide a list of the benefits of the topology.

Although multiple topologies are listed on this page, the listed topologies are not the only options. MariaDB products are flexible, configurable, and extensible, so it possible to deploy different topologies that combine the capabilities of multiple topologies listed on this page. The topologies listed on this page are primarily intended to be representative of the most commonly requested use cases.

Transactional (OLTP)

Primary/Replica Topology

Diagram	Features

Galera Cluster Topology

Columnstore Object Storage

Overview

This procedure describes the deployment of the ColumnStore Object Storage topology with MariaDB Enterprise Server 10.5, MariaDB Enterprise ColumnStore 5, and MariaDB MaxScale 2.5.

MariaDB Enterprise ColumnStore 5 is a columnar storage engine for MariaDB Enterprise Server 10.5. Enterprise ColumnStore is suitable for Online Analytical Processing (OLAP) workloads.

This procedure has 9 steps, which are executed in sequence.

This procedure represents basic product capability and deploys 3 Enterprise ColumnStore nodes and 1 MaxScale node.

This page provides an overview of the topology, requirements, and deployment procedures.

Please read and understand this procedure before executing.

Procedure Steps

Step	Description
Step 1	Prepare ColumnStore Nodes
Step 2	Configure Shared Local Storage
Step 3	Install MariaDB Enterprise Server
Step 4	Start and Configure MariaDB Enterprise Server
Step 5	Test MariaDB Enterprise Server
Step 6	Install MariaDB MaxScale
Step 7	Start and Configure MariaDB MaxScale
Step 8	Test MariaDB MaxScale
Step 9	Import Data

Support

Customers can obtain support by submitting a support case.

Components

The following components are deployed during this procedure:

Component	Function
MariaDB Enterprise Server	Modern SQL RDBMS with high availability, pluggable storage engines, hot online backups, and audit logging.
MariaDB MaxScale	Database proxy that extends the availability, scalability, and security of MariaDB Enterprise Servers

MariaDB Enterprise Server Components

Component	Description
MariaDB Enterprise ColumnStore	• Columnar storage engine • Highly available • Optimized for Online Analytical Processing (OLAP) workloads • Scalable query execution • Cluster Management API (CMAPI) provides a REST API for multi-node administration

MariaDB MaxScale Components

Component	Description
Listener	Listens for client connections to MaxScale then passes them to the router service
MariaDB Monitor	Tracks changes in the state of MariaDB Enterprise Servers.
Read Connection Router	Routes connections from the listener to any available Enterprise ColumnStore node
Read/Write Split Router	Routes read operations from the listener to any available Enterprise ColumnStore node, and routes write operations from the listener to a specific server that MaxScale uses as the primary server
Server Module	Connection configuration in MaxScale to an Enterprise ColumnStore node

Topology

The MariaDB Enterprise ColumnStore topology with Object Storage delivers production analytics with high availability, fault tolerance, and limitless data storage by leveraging S3-compatible storage.

The topology consists of:

- One or more MaxScale nodes
- An odd number of ColumnStore nodes (minimum of 3) running ES, Enterprise ColumnStore, and CMAPI

The MaxScale nodes:

- Monitor the health and availability of each ColumnStore node using the MariaDB Monitor (mariadbmon)
- Accept client and application connections
- Route queries to ColumnStore nodes using the Read/Write Split Router (readwritesplit)

The ColumnStore nodes:

- Receive queries from MaxScale
- Execute queries
- Use S3-compatible object storage for data
- Use shared local storage for the Storage Manager directory

Requirements

These requirements are for the ColumnStore Object Storage topology when deployed with MariaDB Enterprise Server 10.5, MariaDB Enterprise ColumnStore 5, and MariaDB MaxScale 2.5.

- Node Count
- Operating System
- Minimum Hardware Requirements
- Recommended Hardware Requirements
- Storage Requirements

- S3-Compatible Object Storage Requirements
- Preferred Object Storage Providers: Cloud
- Preferred Object Storage Providers: Hardware
- Shared Local Storage Directories
- Shared Local Storage Options
- Recommended Storage Options

Node Count

- MaxScale nodes, 1 or more are required.
- Enterprise ColumnStore nodes, 3 or more are required for high availability. You should always have an odd number of nodes in a multi-node ColumnStore deployment to avoid split brain scenarios.

Operating System

In alignment to the enterprise lifecycle, the ColumnStore Object Storage topology with MariaDB Enterprise Server 10.5, MariaDB Enterprise ColumnStore 5, and MariaDB MaxScale 2.5 is provided for:

- CentOS Linux 7 (x86_64)
- Debian 10 (x86_64)
- Red Hat Enterprise Linux 7 (x86_64)
- Red Hat Enterprise Linux 8 (x86_64)
- Ubuntu 18.04 LTS (x86_64)
- Ubuntu 20.04 LTS (x86_64)

Minimum Hardware Requirements

MariaDB Enterprise ColumnStore's minimum hardware requirements are not intended for production environments, but the minimum hardware requirements can be appropriate for development and test environments. For production environments, see the recommended hardware requirements instead.

The minimum hardware requirements are:

Component	CPU	Memory
MaxScale node	4+ cores	4+ GB
Enterprise ColumnStore node	4+ cores	4+ GB

MariaDB Enterprise ColumnStore will refuse to start if the system has less than 3 GB of memory.

If Enterprise ColumnStore is started on a system with less memory, the following error message will be written to the ColumnStore system log called crit.log:

```
Apr 30 21:54:35 a1ebc96a2519 PrimProc[1004]: 35.668435 |0|0|0| C 28 CAL0000: Error total memory available
is less than 3GB.
```

And the following error message will be raised to the client:

```
ERROR 1815 (HY000): Internal error: System is not ready yet. Please try again.
```

Recommended Hardware Requirements

MariaDB Enterprise ColumnStore's recommended hardware requirements are intended for production analytics.

The recommended hardware requirements are:

Component	CPU	Memory
MaxScale node	8+ cores	16+ GB
Enterprise ColumnStore node	64+ cores	128+ GB

Storage Requirements

The ColumnStore Object Storage topology requires the following storage types:

Storage Type	Description
S3-Compatible Object Storage	The ColumnStore Object Storage topology uses S3-compatible object storage to store data.
Shared Local Storage	The ColumnStore Object Storage topology uses shared local storage for the Storage Manager directory to store metadata.

S3-Compatible Object Storage Requirements

The ColumnStore Object Storage topology uses S3-compatible object storage to store data.

Many S3-compatible object storage services exist. MariaDB Corporation cannot make guarantees about all S3-compatible object storage services, because different services provide different functionality.

For the preferred S3-compatible object storage providers that provide cloud and hardware solutions, see the following sections:

- Cloud
- Hardware

The use of non-cloud and non-hardware providers is at your own risk.

If you have any questions about using specific S3-compatible object storage with MariaDB Enterprise ColumnStore, contact us.

Preferred Object Storage Providers: Cloud

- Amazon Web Services (AWS) S3
- Google Cloud Storage
- Azure Storage
- Alibaba Cloud Object Storage Service

Preferred Object Storage Providers: Hardware

- Cloudian HyperStore
- Cohesity S3
- Dell EMC
- IBM Cloud Object Storage
- Seagate Lyve Rack
- Quantum ActiveScale

Shared Local Storage Directories

The ColumnStore Object Storage topology uses shared local storage for the Storage Manager directory to store metadata.

The Storage Manager directory is located at the following path by default:

- `/var/lib/columnstore/storagemanager`

Shared Local Storage Options

The most common shared local storage options for the ColumnStore Object Storage topology are:

Shared Local Storage	Common Usage	Description
EBS (Elastic Block Store) Multi-Attach	AWS	• EBS is a high-performance block-storage service for AWS (Amazon Web Services). • EBS Multi-Attach allows an EBS volume to be attached to multiple instances in AWS. Only clustered file systems, such as GFS2, are supported. • For deployments in AWS, EBS Multi-Attach is a recommended option for the Storage Manager directory, and Amazon S3 storage is the recommended option for data.
EFS (Elastic File System)	AWS	• EFS is a scalable, elastic, cloud-native NFS file system for AWS (Amazon Web Services). • For deployments in AWS, EFS is a recommended option for the Storage Manager directory, and Amazon S3 storage is the recommended option for data. EFS is a scalable, elastic, cloud-native NFS file system for AWS (Amazon Web Services).
Filestore	GCP	• Filestore is high-performance, fully managed storage for GCP (Google Cloud Platform). • For deployments in GCP, Filestore is the recommended option for the Storage Manager directory, and Google Object Storage (S3-compatible) is the recommended option for data.
GlusterFS	On-premises	• GlusterFS is a distributed file system. • GlusterFS supports replication and failover.
NFS (Network File System)	On-premises	• NFS is a distributed file system. • If NFS is used, the storage should be mounted with the sync option to ensure that each node flushes its changes immediately. • For on-premises deployments, NFS is the recommended option for the Storage Manager directory, and any S3-compatible storage is the recommended option for data.

Recommended Storage Options

For best results, MariaDB Corporation would recommend the following storage options:

Environment	Object Storage For Data	Shared Local Storage For Storage Manager
AWS	Amazon S3 storage	EBS Multi-Attach or EFS
GCP	Google Object Storage (S3-compatible)	Filestore
On-premises	Any S3-compatible object storage	NFS

Enterprise ColumnStore Management with CMAPI

Enterprise ColumnStore's CMAPI (Cluster Management API) is a REST API that can be used to manage a multi-node Enterprise ColumnStore cluster.

Many tools are capable of interacting with REST APIs. For example, the curl utility could be used to make REST API calls from the command-line.

Many programming languages also have libraries for interacting with REST APIs.

The examples below show how to use the CMAPI with curl.

URL Endpoint Format for REST API

```
https://{server}:{port}/cmapi/{version}/{route}/{command}
```

For example:

- `https://mcs1:8640/cmapi/0.4.0/cluster/shutdown`
- `https://mcs1:8640/cmapi/0.4.0/cluster/start`
- `https://mcs1:8640/cmapi/0.4.0/cluster/status`

With CMAPI 1.4 and later:

- `https://mcs1:8640/cmapi/0.4.0/cluster/node`

With CMAPI 1.3 and earlier:

- `https://mcs1:8640/cmapi/0.4.0/cluster/add-node`
- `https://mcs1:8640/cmapi/0.4.0/cluster/remove-node`

Required Request Headers

- `'x-api-key': '93816fa66cc2d8c224e62275bd4f248234dd4947b68d4af2b29671dd7d5532dd'`
- `'Content-Type': 'application/json'`

`x-api-key` can be set to any value of your choice during the first call to the server. Subsequent connections will require this same key.

Get Status

> **NOTE**
>
> `curl` examples remain valid but are now considered **legacy**.

`$ mcs cluster status`

```
$ curl -k -s https://mcs1:8640/cmapi/0.4.0/cluster/status \
      --header 'Content-Type:application/json' \
      --header 'x-api-key:93816fa66cc2d8c224e62275bd4f248234dd4947b68d4af2b29671dd7d5532dd' \
      | jq .
```

Start Cluster

`$ mcs cluster start --timeout 20`

```
$ curl -k -s -X PUT https://mcs1:8640/cmapi/0.4.0/cluster/start \
      --header 'Content-Type:application/json' \
      --header 'x-api-key:93816fa66cc2d8c224e62275bd4f248234dd4947b68d4af2b29671dd7d5532dd' \
      --data '{"timeout":20}' \
      | jq .
```

Stop Cluster

`$ mcs cluster shutdown --timeout 20`

```
$ curl -k -s -X PUT https://mcs1:8640/cmapi/0.4.0/cluster/shutdown \
      --header 'Content-Type:application/json' \
      --header 'x-api-key:93816fa66cc2d8c224e62275bd4f248234dd4947b68d4af2b29671dd7d5532dd' \
      --data '{"timeout":20}' \
      | jq .
```

Add Node

- With CMAPI 1.4 and later:

```
$ curl -k -s -X PUT https://mcs1:8640/cmapi/0.4.0/cluster/node \
      --header 'Content-Type:application/json' \
      --header 'x-api-key:93816fa66cc2d8c224e62275bd4f248234dd4947b68d4af2b29671dd7d5532dd' \
      --data '{"timeout":20, "node": "192.0.2.2"}' \
      | jq .
```

- With CMAPI 1.3 and earlier:

```
$ curl -k -s -X PUT https://mcs1:8640/cmapi/0.4.0/cluster/add-node \
      --header 'Content-Type:application/json' \
      --header 'x-api-key:93816fa66cc2d8c224e62275bd4f248234dd4947b68d4af2b29671dd7d5532dd' \
      --data '{"timeout":20, "node": "192.0.2.2"}' \
      | jq .
```

Remove Node

- With CMAPI 1.4 and later:

```
$ curl -k -s -X DELETE https://mcs1:8640/cmapi/0.4.0/cluster/node \
      --header 'Content-Type:application/json' \
      --header 'x-api-key:93816fa66cc2d8c224e62275bd4f248234dd4947b68d4af2b29671dd7d5532dd' \
      --data '{"timeout":20, "node": "192.0.2.2"}' \
      | jq .
```

- With CMAPI 1.3 and earlier:

```
$ curl -k -s -X PUT https://mcs1:8640/cmapi/0.4.0/cluster/remove-node \
      --header 'Content-Type:application/json' \
      --header 'x-api-key:93816fa66cc2d8c224e62275bd4f248234dd4947b68d4af2b29671dd7d5532dd' \
      --data '{"timeout":20, "node": "192.0.2.2"}' \
      | jq .
```

Quick Reference

MariaDB Enterprise Server Configuration Management

Method	Description
Configuration File	Configuration files (such as /etc/my.cnf) can be used to set system-variables and options. The server must be restarted to apply changes made to configuration files.
Command-line	The server can be started with command-line options that set system-variables and options.
SQL	Users can set system-variables that support dynamic changes on-the-fly using the SET statement.

MariaDB Enterprise Server packages are configured to read configuration files from different paths, depending on the operating system. Making custom changes to Enterprise Server default configuration files is not recommended because custom changes may be overwritten by other default configuration files that are loaded later.

To ensure that your custom changes will be read last, create a custom configuration file with the z- prefix in one of the include directories.

Distribution	Example Configuration File Path
Distribution	Example Configuration File Path
• CentOS • Red Hat Enterprise Linux (RHEL)	/etc/my.cnf.d/z-custom-mariadb.cnf

Distribution	Example Configuration File Path
• Debian • Ubuntu	/etc/mysql/mariadb.conf.d/z-custom-mariadb.cnf

MariaDB Enterprise Server Service Management

The systemctl command is used to start and stop the MariaDB Enterprise Server service.

Operation	Command
Start	`sudo systemctl start mariadb`
Stop	`sudo systemctl stop mariadb`
Restart	`sudo systemctl restart mariadb`
Enable during startup	`sudo systemctl enable mariadb`
Disable during startup	`sudo systemctl disable mariadb`
Status	`sudo systemctl status mariadb`

For additional information, see "Starting and Stopping MariaDB".

MariaDB Enterprise Server Logs

MariaDB Enterprise Server produces log data that can be helpful in problem diagnosis.

Log filenames and locations may be overridden in the server configuration. The default location of logs is the data directory. The data directory is specified by the datadir system variable.

Log	System Variable/Option	Default Filename
MariaDB Error Log	log_error	`<hostname>.err`
MariaDB Enterprise Audit Log	server_audit_file_path	`server_audit.log`
Slow Query Log	slow_query_log_file	`<hostname>-slow.log`
General Query Log	general_log_file	`<hostname>.log`
Binary Log	log_bin	`<hostname>-bin`

Enterprise ColumnStore Service Management

The systemctl command is used to start and stop the ColumnStore service.

Operation	Command
Start	`sudo systemctl start mariadb-columnstore`
Stop	`sudo systemctl stop mariadb-columnstore`
Restart	`sudo systemctl restart mariadb-columnstore`
Enable during startup	`sudo systemctl enable mariadb-columnstore`
Disable during startup	`sudo systemctl disable mariadb-columnstore`
Status	`sudo systemctl status mariadb-columnstore`

In the ColumnStore Object Storage topology, the mariadb-columnstore service should not be enabled. The CMAPI service restarts Enterprise ColumnStore as needed, so it does not need to start automatically upon reboot.

Enterprise ColumnStore CMAPI Service Management

The systemctl command is used to start and stop the CMAPI service.

Operation	Command
Start	`sudo systemctl start mariadb-columnstore-cmapi`
Stop	`sudo systemctl stop mariadb-columnstore-cmapi`
Restart	`sudo systemctl restart mariadb-columnstore-cmapi`
Enable during startup	`sudo systemctl enable mariadb-columnstore-cmapi`
Disable during startup	`sudo systemctl disable mariadb-columnstore-cmapi`
Status	`sudo systemctl status mariadb-columnstore-cmapi`

For additional information on endpoints, see “CMAPI”.

MaxScale Configuration Management

MaxScale can be configured using several methods. These methods make use of MaxScale’s REST API.

Method	Benefits
MaxCtrl	Command-line utility to perform administrative tasks through the REST API. See MaxCtrl Commands.
MaxGUI	MaxGUI is a graphical utility that can perform administrative tasks through the REST API.
REST API	The REST API can be used directly. For example, the curl utility could be used to make REST API calls from the command-line. Many programming languages also have libraries to interact with REST APIs.

The procedure on these pages configures MaxScale using MaxCtrl.

MaxScale Service Management

The `systemctl` command is used to start and stop the MaxScale service.

Operation	Command
Start	`sudo systemctl start maxscale`
Stop	`sudo systemctl stop maxscale`
Restart	`sudo systemctl restart maxscale`
Enable during startup	`sudo systemctl enable maxscale`
Disable during startup	`sudo systemctl disable maxscale`
Status	`sudo systemctl status maxscale`

For additional information, see “Starting and Stopping MariaDB”.

Next Step

Navigation in the procedure “Deploy ColumnStore Object Storage Topology”:

Next: Step 1: Prepare ColumnStore Nodes.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 1: Prepare ColumnStore Nodes

Overview

This page details step 1 of the 9-step procedure “Deploy ColumnStore Object Storage Topology”.

This step prepares systems to host MariaDB Enterprise Server and MariaDB Enterprise ColumnStore 23.10.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Optimize Linux Kernel Parameters

MariaDB Enterprise ColumnStore performs best with Linux kernel optimizations.

On each server to host an Enterprise ColumnStore node, optimize the kernel:

1. Set the relevant kernel parameters in a sysctl configuration file. To ensure proper change management, use an Enterprise ColumnStore-specific configuration file.

Create `a /etc/sysctl.d/90-mariadb-enterprise-columnstore.conf file`:

```
# minimize swapping
vm.swappiness = 1

# Increase the TCP max buffer size
net.core.rmem_max = 16777216
net.core.wmem_max = 16777216

# Increase the TCP buffer limits
# min, default, and max number of bytes to use
net.ipv4.tcp_rmem = 4096 87380 16777216
net.ipv4.tcp_wmem = 4096 65536 16777216

# don't cache ssthresh from previous connection
net.ipv4.tcp_no_metrics_save = 1

# for 1 GigE, increase this to 2500
# for 10 GigE, increase this to 30000
net.core.netdev_max_backlog = 2500
```

2. Use the sysctl command to set the kernel parameters at runtime

```
$ sudo sysctl --load=/etc/sysctl.d/90-mariadb-enterprise-columnstore.conf
```

Temporarily Configure Linux Security Modules (LSM)

The Linux Security Modules (LSM) should be temporarily disabled on each Enterprise ColumnStore node during installation.

The LSM will be configured and re-enabled later in this deployment procedure.

The steps to disable the LSM depend on the specific LSM used by the operating system.

CentOS / RHEL Stop SELinux

SELinux must be set to permissive mode before installing MariaDB Enterprise ColumnStore.

To set SELinux to permissive mode:

1. Set SELinux to permissive mode:

```
$ sudo setenforce permissive
```

2. Set SELinux to permissive mode by setting SELINUX=permissive in /etc/selinux/config.

For example, the file will usually look like this after the change:

```
# This file controls the state of SELinux on the system.
# SELINUX= can take one of these three values:
#     enforcing - SELinux security policy is enforced.
#     permissive - SELinux prints warnings instead of enforcing.
#     disabled - No SELinux policy is loaded.
SELINUX=permissive
# SELINUXTYPE= can take one of three values:
#     targeted - Targeted processes are protected,
#     minimum - Modification of targeted policy. Only selected processes are protected.
#     mls - Multi Level Security protection.
SELINUXTYPE=targeted
```

3. Confirm that SELinux is in permissive mode:

```
$ sudo getenforce
Permissive
```

SELinux will be configured and re-enabled later in this deployment procedure. This configuration is not persistent. If you restart the server before configuring and re-enabling SELinux later in the deployment procedure, you must reset the enforcement to permissive mode.

Debian / Ubuntu AppArmor

AppArmor must be disabled before installing MariaDB Enterprise ColumnStore.

1. Disable AppArmor:

```
$ sudo systemctl disable apparmor
```

2. Reboot the system.
3. Confirm that no AppArmor profiles are loaded using aa-status:

```
$ sudo aa-status
```

```
apparmor module is loaded.
0 profiles are loaded.
0 profiles are in enforce mode.
0 profiles are in complain mode.
0 processes have profiles defined.
0 processes are in enforce mode.
0 processes are in complain mode.
0 processes are unconfined but have a profile defined.
```

AppArmor will be configured and re-enabled later in this deployment procedure.

Temporarily Configure Firewall for Installation

MariaDB Enterprise ColumnStore requires the following TCP ports:

TCP Ports	Description
3306	Port used for MariaDB Client traffic
8600-8630	Port range used for inter-node communication
8640	Port used by CMAPI
8700	Port used for inter-node communication
8800	Port used for inter-node communication

The firewall should be temporarily disabled on each Enterprise ColumnStore node during installation.

The firewall will be configured and re-enabled later in this deployment procedure.

The steps to disable the firewall depend on the specific firewall used by the operating system.

CentOS / RHEL Stop firewalld

1. Check if the firewalld service is running:

```
$ sudo systemctl status firewalld
```

2. If the firewalld service is running, stop it:

```
$ sudo systemctl stop firewalld
```

Firewalld will be configured and re-enabled later in this deployment procedure.

Ubuntu Stop UFW

1. Check if the UFW service is running:

```
$ sudo ufw status verbose
```

2. If the UFW service is running, stop it:

```
$ sudo ufw disable
```

UFW will be configured and re-enabled later in this deployment procedure.

Configure the AWS Security Group

To install Enterprise ColumnStore on Amazon Web Services (AWS), the security group must be modified prior to installation.

Enterprise ColumnStore requires all internal communications to be open between Enterprise ColumnStore nodes. Therefore, the security group should allow all protocols and all ports to be open between the Enterprise ColumnStore nodes and the MaxScale proxy.

Configure Character Encoding

When using MariaDB Enterprise ColumnStore, it is recommended to set the system's locale to UTF-8.

1. On RHEL 8, install additional dependencies:

```
$ sudo yum install glibc-locale-source glibc-langpack-en
```

2. Set the system's locale to en_US.UTF-8 by executing localedef:

```
$ sudo localedef -i en_US -f UTF-8 en_US.UTF-8
```

Configure DNS

MariaDB Enterprise ColumnStore requires all nodes to have host names that are resolvable on all other nodes. If your infrastructure does not configure DNS centrally, you may need to configure static DNS entries in the /etc/hosts file of each server.

On each Enterprise ColumnStore node, edit the /etc/hosts file to map host names to the IP address of each Enterprise ColumnStore node:

```
192.0.2.1     mcs1
192.0.2.2     mcs2
192.0.2.3     mcs3
192.0.2.100   mxs1
```

Replace the IP addresses with the addresses in your own environment.

Create an S3 Bucket

With the ColumnStore Object Storage topology, it is important to create the S3 bucket before you start ColumnStore. All Enterprise ColumnStore nodes access data from the same bucket.

If you already have an S3 bucket, confirm that the bucket is empty.

S3 bucket configuration will be performed later in this procedure.

Next Step

Navigation in the procedure “Deploy ColumnStore Object Storage Topology”:

This page was step 1 of 9.

Next: Step 2: Configure Shared Local Storage.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 2: Configure Shared Local Storage

Overview

This page details step 2 of the 9-step procedure “Deploy ColumnStore Object Storage Topology”.

This step configures shared local storage on systems hosting Enterprise ColumnStore 23.10.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Directories for Shared Local Storage

In a ColumnStore Object Storage topology, MariaDB Enterprise ColumnStore requires the Storage Manager directory to be located on shared local storage.

The Storage Manager directory is at the following path:

- `/var/lib/columnstore/storagemanager`

The Storage Manager directory must be mounted on every ColumnStore node.

Choose a Shared Local Storage Solution

Select a Shared Local Storage solution for the Storage Manager directory:

- EBS (Elastic Block Store) Multi-Attach
- EFS (Elastic File System)
- Filestore
- GlusterFS
- NFS (Network File System)

For additional information, see “Shared Local Storage Options”.

Configure EBS Multi-Attach

EBS is a high-performance block-storage service for AWS (Amazon Web Services). EBS Multi-Attach allows an EBS volume to be attached to multiple instances in AWS. Only clustered file systems, such as GFS2, are supported.

For Enterprise ColumnStore deployments in AWS:

- EBS Multi-Attach is a recommended option for the Storage Manager directory.
- Amazon S3 storage is the recommended option for data.
- Consult the vendor documentation for details on how to configure EBS Multi-Attach.

Configure Elastic File System (EFS)

EFS is a scalable, elastic, cloud-native NFS file system for AWS (Amazon Web Services)

For deployments in AWS:

- EFS is a recommended option for the Storage Manager directory.
- Amazon S3 storage is the recommended option for data.
- Consult the vendor documentation for details on how to configure EFS.

Configure Filestore

Filestore is high-performance, fully managed storage for GCP (Google Cloud Platform).

For Enterprise ColumnStore deployments in GCP:

- Filestore is the recommended option for the Storage Manager directory.
- Google Object Storage (S3-compatible) is the recommended option for data.
- Consult the vendor documentation for details on how to configure Filestore.

Configure GlusterFS

GlusterFS is a distributed file system.

GlusterFS is a shared local storage option, but it is not one of the recommended options.

For more information, see “Recommended Storage Options”.

Install GlusterFS

On each Enterprise ColumnStore node, install GlusterFS.

Install on CentOS / RHEL 8 (YUM):

```
$ sudo yum install --enablerepo=PowerTools glusterfs-server
```

Install on CentOS / RHEL 7 (YUM):

```
$ sudo yum install centos-release-gluster
$ sudo yum install glusterfs-server
```

Install on Debian (APT):

```
$ wget -O - https://download.gluster.org/pub/gluster/glusterfs/LATEST/rsa.pub | apt-key add -

$ DEBID=$(grep 'VERSION_ID=' /etc/os-release | cut -d '=' -f 2 | tr -d '"')
$ DEBVER=$(grep 'VERSION=' /etc/os-release | grep -Eo '[a-z]+')
$ DEBARCH=$(dpkg --print-architecture)
$ echo deb https://download.gluster.org/pub/gluster/glusterfs/LATEST/Debian/${DEBID}/${DEBARCH}/apt
${DEBVER} main > /etc/apt/sources.list.d/gluster.list
```

```
$ sudo apt update
```

```
$ sudo apt install glusterfs-server
```

Install on Ubuntu (APT):

```
$ sudo apt update
```

```
$ sudo apt install glusterfs-server
```

Start the GlusterFS Daemon

Start the GlusterFS daemon:

```
$ sudo systemctl start glusterd
```

```
$ sudo systemctl enable glusterd
```

Probe the GlusterFS Peers

Before you can create a volume with GlusterFS, you must probe each node from a peer node.

1. On the primary node, probe all of the other cluster nodes:

```
$ sudo gluster peer probe mcs2
```

```
$ sudo gluster peer probe mcs3
```

2. On one of the replica nodes, probe the primary node to confirm that it is connected:

```
$ sudo gluster peer probe mcs1
```

```
peer probe: Host mcs1 port 24007 already in peer list
```

3. On the primary node, check the peer status:

```
$ sudo gluster peer status
```

```
Number of Peers: 2

Hostname: mcs2
Uuid: 3c8a5c79-22de-45df-9034-8ae624b7b23e
State: Peer in Cluster (Connected)

Hostname: mcs3
Uuid: 862af7b2-bb5e-4b1c-8311-630fa32ed451
State: Peer in Cluster (Connected)
```

Configure and Mount GlusterFS Volumes

Create the GlusterFS volumes for MariaDB Enterprise ColumnStore. Each volume must have the same number of replicas as the number of Enterprise ColumnStore nodes.

1. On each Enterprise ColumnStore node, create the directory for each brick in the /brick directory:

```
$ sudo mkdir -p /brick/storagemanager
```

2. On the primary node, create the GlusterFS volumes:

```
$ sudo gluster volume create storagemanager \
      replica 3 \
      mcs1:/brick/storagemanager \
      mcs2:/brick/storagemanager \
      mcs3:/brick/storagemanager \
      force
```

3. On the primary node, start the volume:

```
$ sudo gluster volume start storagemanager
```

4. On each Enterprise ColumnStore node, create mount points for the volumes:

```
$ sudo mkdir -p /var/lib/columnstore/storagemanager
```

5. On each Enterprise ColumnStore node, add the mount points to /etc/fstab:

```
127.0.0.1:storagemanager /var/lib/columnstore/storagemanager glusterfs defaults,_netdev 0 0
```

6. On each Enterprise ColumnStore node, mount the volumes:

```
$ sudo mount -a
```

Configure Network File System (NFS)

NFS is a distributed file system. NFS is available in most Linux distributions. If NFS is used for an Enterprise ColumnStore deployment, the storage must be mounted with the sync option to ensure that each node flushes its changes immediately.

For on-premises deployments:

- NFS is the recommended option for the Storage Manager directory.
- Any S3-compatible storage is the recommended option for data.

Consult the documentation for your NFS implementation for details on how to configure NFS.

Next Step

Navigation in the procedure “Deploy ColumnStore Object Storage Topology”:

This page was **step 2 of 9**.

Next: Step 3: Install MariaDB Enterprise Server.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 3: Install MariaDB Enterprise Server

Overview

This page details step 3 of the 9-step procedure “Deploy ColumnStore Object Storage Topology”.

This step installs MariaDB Enterprise Server, MariaDB Enterprise ColumnStore 23.10, CMAPI, and dependencies.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Retrieve Download Token

MariaDB Corporation provides package repositories for CentOS / RHEL (YUM) and Debian / Ubuntu (APT). A download token is required to access the MariaDB Enterprise Repository.

Customer Download Tokens are customer-specific and are available through the MariaDB Customer Portal.

To retrieve the token for your account:

1. Navigate to https://customers.mariadb.com/downloads/token/
2. Log in.
3. Copy the Customer Download Token.

Substitute your token for `CUSTOMER_DOWNLOAD_TOKEN` when configuring the package repositories.

Set Up Repository

1. On each Enterprise ColumnStore node, install the prerequisites for downloading the software from the Web. Install on CentOS / RHEL (YUM):

```
$ sudo yum install curl
```

Install on Debian / Ubuntu (APT):

```
$ sudo apt install curl apt-transport-https
```

2. On each Enterprise ColumnStore node, configure package repositories and specify Enterprise Server:

```
$ curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
```

```
$ echo "${checksum}  mariadb_es_repo_setup" \
       | sha256sum -c -
```

```
$ chmod +x mariadb_es_repo_setup
```

```
$ sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
      --skip-maxscale \
      --skip-tools \
      --mariadb-server-version="11.4"
```

Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.

Install Enterprise Server and Enterprise ColumnStore

1. On each Enterprise ColumnStore node, install additional dependencies:

Install on CentOS and RHEL (YUM):

```
$ sudo yum install jemalloc jq curl
```

Install on Debian 9 and Ubuntu 18.04 (APT)

```
$ sudo apt install libjemalloc1 jq curl
```

Install on Debian 10 and Ubuntu 20.04 (APT):

```
$ sudo apt install libjemalloc2 jq curl
```

2. On each Enterprise ColumnStore node, install MariaDB Enterprise Server and MariaDB Enterprise ColumnStore:

Install on CentOS / RHEL (YUM):

```
$ sudo yum install MariaDB-server \
   MariaDB-backup \
   MariaDB-shared \
   MariaDB-client \
   MariaDB-columnstore-engine \
   MariaDB-columnstore-cmapi
```

Install on Debian / Ubuntu (APT):

```
$ sudo apt install mariadb-server \
   mariadb-backup \
   libmariadb3 \
   mariadb-client \
   mariadb-plugin-columnstore \
   mariadb-columnstore-cmapi
```

Next Step

Navigation in the procedure “Deploy ColumnStore Object Storage Topology”.

This page was **step 3 of 9**.

Next: Step 4: Start and Configure MariaDB Enterprise Server.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 4: Start and Configure MariaDB Enterprise Server

Overview

This page details step 4 of the 9-step procedure “Deploy ColumnStore Object Storage Topology”.

This step starts and configures MariaDB Enterprise Server, and MariaDB Enterprise ColumnStore 23.10.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Stop the Enterprise ColumnStore Services

The installation process might have started some of the ColumnStore services. The services should be stopped prior to making configuration changes.

1. On each Enterprise ColumnStore node, stop the MariaDB Enterprise Server service:

```
$ sudo systemctl stop mariadb
```

2. On each Enterprise ColumnStore node, stop the MariaDB Enterprise ColumnStore service:

```
$ sudo systemctl stop mariadb-columnstore
```

3. On each Enterprise ColumnStore node, stop the CMAPI service:

```
$ sudo systemctl stop mariadb-columnstore-cmapi
```

Configure Enterprise ColumnStore

On each Enterprise ColumnStore node, configure Enterprise Server.

Connector	MariaDB Connector/R2DBC
character_set_server	Set this system variable to `utf8`
collation_server	Set this system variable to `utf8_general_ci`
loose-columnstore_use_import_for_batchinsert	Set this system variable to ALWAYS to always use cpimport for LOAD DATA INFILE and INSERT…SELECT statements.
gtid_strict_mode	Set this system variable to ON.
log_bin	Set this option to the file you want to use for the Binary Log. Setting this option enables binary logging.
log_bin_index	Set this option to the file you want to use to track binlog filenames.
log_slave_updates	Set this system variable to ON.
relay_log	Set this option to the file you want to use for the Relay Logs. Setting this option enables relay logging.
relay_log_index	Set this option to the file you want to use to index Relay Log filenames.
server_id	Sets the numeric Server ID for this MariaDB Enterprise Server. The value set on this option must be unique to each node.

> **Warning:**
>
> The `loose-` prefix is required for ColumnStore system variables in the configuration file. Without it, MariaDB Server will fail to start if the ColumnStore plugin is not installed or has been removed.

Mandatory system variables and options for ColumnStore Object Storage include:

Example Configuration

```
[mariadb]
bind_address                            = 0.0.0.0
log_error                               = mariadbd.err
character_set_server                    = utf8
collation_server                        = utf8_general_ci
log_bin                                 = mariadb-bin
log_bin_index                           = mariadb-bin.index
relay_log                               = mariadb-relay
relay_log_index                         = mariadb-relay.index
log_slave_updates                       = ON
gtid_strict_mode                        = ON

# This must be unique on each Enterprise ColumnStore node
server_id                               = 1
```

Configure the S3 Storage Manager

On each Enterprise ColumnStore node, configure S3 Storage Manager to use S3-compatible storage by editing the /etc/columnstore/storagemanager.cnf configuration file:

```
[ObjectStorage]
…
service = S3
…
[S3]
bucket                = your_columnstore_bucket_name
endpoint              = your_s3_endpoint
aws_access_key_id     = your_s3_access_key_id
aws_secret_access_key = your_s3_secret_key
# iam_role_name       = your_iam_role
# sts_region          = your_sts_region
# sts_endpoint        = your_sts_endpoint
# ec2_iam_mode        = enabled

[Cache]
cache_size = your_local_cache_size
path       = your_local_cache_path
```

The S3-compatible object storage options are configured under [S3]:

- The bucket option must be set to the name of the bucket that you created in “Create an S3 Bucket”.
- The endpoint option must be set to the endpoint for the S3-compatible object storage.
- The `aws_access_key_id and aws_secret_access_key` options must be set to the access key ID and secret access key for the S3-compatible object storage.
- To use a specific IAM role, you must uncomment and set `iam_role_name, sts_region, and sts_endpoint`.
- To use the IAM role assigned to an EC2 instance, you must uncomment `ec2_iam_mode=enabled`.

The local cache options are configured under [Cache]:

- The cache_size option is set to 2 GB by default.
- The path option is set to `/var/lib/columnstore/storagemanager/cache` by default.

Ensure that the specified path has sufficient storage space for the specified cache size.

Start the Enterprise ColumnStore Services

1. On each Enterprise ColumnStore node, start and enable the MariaDB Enterprise Server service, so that it starts automatically upon reboot:

```
$ sudo systemctl start mariadb
```

```
$ sudo systemctl enable mariadb
```

2. On each Enterprise ColumnStore node, stop the MariaDB Enterprise ColumnStore service:

```
$ sudo systemctl stop mariadb-columnstore
```

After the CMAPI service is installed in the next step, CMAPI will start the Enterprise ColumnStore service as-needed on each node. CMAPI disables the Enterprise ColumnStore service to prevent systemd from automatically starting Enterprise ColumnStore upon reboot.

3. On each Enterprise ColumnStore node, start and enable the CMAPI service, so that it starts automatically upon reboot:

```
$ sudo systemctl start mariadb-columnstore-cmapi
```

```
$ sudo systemctl enable mariadb-columnstore-cmapi
```

For additional information, see “Starting and Stopping MariaDB”.

Create User Accounts

The ColumnStore Object Storage topology requires several user accounts. Each user account should be created on the primary server, so that it is replicated to the replica servers.

Create the Utility User

Enterprise ColumnStore requires a mandatory utility user account to perform cross-engine joins and similar operations.

1. On the primary server, create the user account with the CREATE USER statement:

```
CREATE USER 'util_user'@'127.0.0.1'
IDENTIFIED BY 'util_user_passwd';
```

2. On the primary server, grant the user account SELECT privileges on all databases with the GRANT statement:

```
GRANT SELECT, PROCESS ON *.*
TO 'util_user'@'127.0.0.1';
```

3. On each Enterprise ColumnStore node, configure the ColumnStore utility user:

```
$ sudo mcsSetConfig CrossEngineSupport Host 127.0.0.1
```

```
$ sudo mcsSetConfig CrossEngineSupport Port 3306
```

```
$ sudo mcsSetConfig CrossEngineSupport User util_user
```

4. On each Enterprise ColumnStore node, set the password:

```
$ sudo mcsSetConfig CrossEngineSupport Password util_user_passwd
```

For details about how to encrypt the password, see “Credentials Management for MariaDB Enterprise ColumnStore”.

Passwords should meet your organization’s password policies. If your MariaDB Enterprise Server instance has a password validation plugin installed, then the password should also meet the configured requirements.

Create the Replication User

ColumnStore Object Storage uses MariaDB Replication to replicate writes between the primary and replica servers. As MaxScale can promote a replica server to become a new primary in the event of node failure, all nodes must have a replication user.

The action is performed **on the primary server**.

Create the replication user and grant it the required privileges:

1. Use the CREATE USER statement to create replication user.

```
CREATE USER 'repl'@'192.0.2.%' IDENTIFIED BY 'repl_passwd';
```

Replace the referenced IP address with the relevant address for your environment.

Ensure that the user account can connect to the primary server from each replica.

2. Grant the user account the required privileges with the GRANT statement.

```
GRANT REPLICA MONITOR,
   REPLICATION REPLICA,
   REPLICATION REPLICA ADMIN,
   REPLICATION MASTER ADMIN
ON *.* TO 'repl'@'192.0.2.%';
```

Create MaxScale User

ColumnStore Object Storage 23.10 uses MariaDB MaxScale 22.08 to load balance between the nodes.

This action is performed on the primary server.

1. Use the CREATE USER statement to create the MaxScale user:

```
CREATE USER 'mxs'@'192.0.2.%'
IDENTIFIED BY 'mxs_passwd';
```

Replace the referenced IP address with the relevant address for your environment.

Ensure that the user account can connect from the IP address of the MaxScale instance.

2. Use the GRANT statement to grant the privileges required by the router:

```
GRANT SHOW DATABASES ON *.* TO 'mxs'@'192.0.2.%';

GRANT SELECT ON mysql.columns_priv TO 'mxs'@'192.0.2.%';

GRANT SELECT ON mysql.db TO 'mxs'@'192.0.2.%';

GRANT SELECT ON mysql.procs_priv TO 'mxs'@'192.0.2.%';

GRANT SELECT ON mysql.proxies_priv TO 'mxs'@'192.0.2.%';

GRANT SELECT ON mysql.roles_mapping TO 'mxs'@'192.0.2.%';

GRANT SELECT ON mysql.tables_priv TO 'mxs'@'192.0.2.%';

GRANT SELECT ON mysql.user TO 'mxs'@'192.0.2.%';
```

3. Use the GRANT statement to grant privileges required by the MariaDB Monitor.

```
GRANT BINLOG ADMIN,
   READ_ONLY ADMIN,
   RELOAD,
   REPLICA MONITOR,
   REPLICATION MASTER ADMIN,
   REPLICATION REPLICA ADMIN,
   REPLICATION REPLICA,
   SHOW DATABASES,
   SELECT
ON *.* TO 'mxs'@'192.0.2.%';
```

Configure MariaDB Replication

On each replica server, configure MariaDB Replication:

1. Use the CHANGE MASTER TO statement to configure the connection to the primary server:

```
CHANGE MASTER TO
   MASTER_HOST='192.0.2.1',
   MASTER_USER='repl',
   MASTER_PASSWORD='repl_passwd',
   MASTER_USE_GTID=slave_pos;
```

2. Start replication using the START REPLICA statement:

```
START REPLICA;
```

3. Confirm that replication is working using the SHOW REPLICA STATUS statement:

```
SHOW REPLICA STATUS;
```

Ensure that the replica server cannot accept local writes by setting the read_only system variable to ON using the SET GLOBAL statement:

```
SET GLOBAL read_only=ON;
```

Initiate the Primary Server with CMAPI

Initiate the primary server using CMAPI.

1. Create an API key for the cluster.
   This API key should be stored securely and kept confidential, because it can be used to add cluster nodes to the multi-node Enterprise ColumnStore deployment.

For example, to create a random 256-bit API key using openssl rand:

```
$ openssl rand -hex 32

93816fa66cc2d8c224e62275bd4f248234dd4947b68d4af2b29671dd7d5532dd
```

This document will use the following API key in further examples, but users should create their own:

2. Use CMAPI to add the primary server to the cluster and set the API key.
   The new API key needs to be provided as part of the X-API-key HTML header.

For example, if the primary server's host name is mcs1 and its IP address is 192.0.2.1, use the following node command:

```
$ curl -k -s -X PUT https://mcs1:8640/cmapi/0.4.0/cluster/node \
   --header 'Content-Type:application/json' \
   --header 'x-api-key:93816fa66cc2d8c224e62275bd4f248234dd4947b68d4af2b29671dd7d5532dd' \
   --data '{"timeout":120, "node": "192.0.2.1"}' \
   | jq .
```

```
{
  "timestamp": "2020-10-28 00:39:14.672142",
  "node_id": "192.0.2.1"
}
```

3. Use CMAPI to check the status of the cluster node:

```
$ curl -k -s https://mcs1:8640/cmapi/0.4.0/cluster/status \
   --header 'Content-Type:application/json' \
   --header 'x-api-key:93816fa66cc2d8c224e62275bd4f248234dd4947b68d4af2b29671dd7d5532dd' \
   | jq .
```

```
{
  "timestamp": "2020-12-15 00:40:34.353574",
  "192.0.2.1": {
    "timestamp": "2020-12-15 00:40:34.362374",
    "uptime": 11467,
    "dbrm_mode": "master",
    "cluster_mode": "readwrite",
    "dbroots": [
      "1"
    ],
    "module_id": 1,
    "services": [
      {
        "name": "workernode",
        "pid": 19202
      },
      {
        "name": "controllernode",
        "pid": 19232
      },
      {
        "name": "PrimProc",
        "pid": 19254
      },
      {
        "name": "ExeMgr",
        "pid": 19292
      },
      {
        "name": "WriteEngine",
        "pid": 19316
      },
      {
        "name": "DMLProc",
        "pid": 19332
      },
      {
        "name": "DDLProc",
        "pid": 19366
      }
    ]
  }
```

Add Replica Servers with CMAPI

Add the replica servers with CMAPI:

1. For each replica server, use CMAPI to add the replica server to the cluster.
   The previously set API key needs to be provided as part of the X-API-key HTML header.

For example, if the primary server's host name is mcs1 and the replica server's IP address is 192.0.2.2, use the following node command:

```
$ curl -k -s -X PUT https://mcs1:8640/cmapi/0.4.0/cluster/node \
   --header 'Content-Type:application/json' \
   --header 'x-api-key:93816fa66cc2d8c224e62275bd4f248234dd4947b68d4af2b29671dd7d5532dd' \
   --data '{"timeout":120, "node": "192.0.2.2"}' \
   | jq .
```

```
{
  "timestamp": "2020-10-28 00:42:42.796050",
  "node_id": "192.0.2.2"
}
```

2. After all replica servers have been added, use CMAPI to confirm that all cluster nodes have been successfully added:

```
$ curl -k -s https://mcs1:8640/cmapi/0.4.0/cluster/status \
   --header 'Content-Type:application/json' \
   --header 'x-api-key:93816fa66cc2d8c224e62275bd4f248234dd4947b68d4af2b29671dd7d5532dd' \
   | jq .
```

```
{
  "timestamp": "2020-12-15 00:40:34.353574",
  "192.0.2.1": {
    "timestamp": "2020-12-15 00:40:34.362374",
    "uptime": 11467,
    "dbrm_mode": "master",
    "cluster_mode": "readwrite",
    "dbroots": [
      "1"
    ],
    "module_id": 1,
    "services": [
      {
        "name": "workernode",
        "pid": 19202
      },
      {
        "name": "controllernode",
        "pid": 19232
      },
      {
        "name": "PrimProc",
        "pid": 19254
      },
      {
        "name": "ExeMgr",
        "pid": 19292
      },
      {
        "name": "WriteEngine",
        "pid": 19316
      },
      {
        "name": "DMLProc",
        "pid": 19332
      },
      {
        "name": "DDLProc",
        "pid": 19366
      }
    ]
  },
  "192.0.2.2": {
    "timestamp": "2020-12-15 00:40:34.428554",
    "uptime": 11437,

    "cluster_mode": "readonly",
    "dbroots": [
      "2"
    ],
    "module_id": 2,
    "services": [
      {
        "name": "workernode",
        "pid": 17789
      },
      {
        "name": "PrimProc",
        "pid": 17813
      },
      {
        "name": "ExeMgr",
        "pid": 17854
      },
      {
        "name": "WriteEngine",
        "pid": 17877
      }
```

```
    ]
  },
  "192.0.2.3": {
    "timestamp": "2020-12-15 00:40:34.428554",
    "uptime": 11437,
    "dbrm_mode": "slave",
    "cluster_mode": "readonly",
    "dbroots": [
      "2"
    ],
    "module_id": 2,
    "services": [
      {
        "name": "workernode",
        "pid": 17789
      },
      {
        "name": "PrimProc",
        "pid": 17813
      },
      {
        "name": "ExeMgr",
        "pid": 17854
      },
      {
        "name": "WriteEngine",
        "pid": 17877
      }
    ]
  },
  "num_nodes": 3
}
```

Configure Linux Security Modules (LSM)

The specific steps to configure the security module depend on the operating system.

Configure SELinux (CentOS, RHEL)

Configure SELinux for Enterprise ColumnStore:

1. To configure SELinux, you have to install the packages required for audit2allow.
   On CentOS 7 and RHEL 7, install the following:

```
$ sudo yum install policycoreutils policycoreutils-python
```

On RHEL 8, install the following:

```
$ sudo yum install policycoreutils python3-policycoreutils policycoreutils-python-utils
```

2. Allow the system to run under load for a while to generate SELinux audit events.
3. After the system has taken some load, generate an SELinux policy from the audit events using audit2allow:

```
$ sudo grep mysqld /var/log/audit/audit.log | audit2allow -M mariadb_local
```

If no audit events were found, this will print the following:

```
$ sudo grep mysqld /var/log/audit/audit.log | audit2allow -M mariadb_local

Nothing to do
```

4. If audit events were found, the new SELinux policy can be loaded using semodule:

```
$ sudo semodule -i mariadb_local.pp
```

5. Set SELinux to enforcing mode:

```
$ sudo setenforce enforcing
```

6. Set SELinux to enforcing mode by setting SELINUX=enforcing in /etc/selinux/config.

For example, the file will usually look like this after the change:

```
# This file controls the state of SELinux on the system.
# SELINUX= can take one of these three values:
#     enforcing - SELinux security policy is enforced.
#     permissive - SELinux prints warnings instead of enforcing.
#     disabled - No SELinux policy is loaded.
SELINUX=enforcing
# SELINUXTYPE= can take one of three values:
#     targeted - Targeted processes are protected,
#     minimum - Modification of targeted policy. Only selected processes are protected.
#     mls - Multi Level Security protection.
SELINUXTYPE=targeted
```

7. Confirm that SELinux is in enforcing mode:

```
$ sudo getenforce
```

```
Enforcing
```

Configure AppArmor (Ubuntu)

For information on how to create a profile, see How to create an AppArmor Profile on Ubuntu.com.

Configure Firewalls

The specific steps to configure the firewall service depend on the platform.

Configure firewalld (CentOS, RHEL)

Configure firewalld for Enterprise Cluster on CentOS and RHEL:

1. Check if the firewalld service is running:

```
$ sudo systemctl status firewalld
```

2. If the firewalld service was stopped to perform the installation, start it now:

For example, if your cluster nodes are in the 192.0.2.0/24 subnet:

```
$ sudo systemctl start firewalld
```

3. Open up the relevant ports using firewall-cmd:

```
$ sudo firewall-cmd --permanent --add-rich-rule='
   rule family="ipv4"
   source address="192.0.2.0/24"
   destination address="192.0.2.0/24"
   port port="3306" protocol="tcp"
   accept'
```

```
$ sudo firewall-cmd --permanent --add-rich-rule='
   rule family="ipv4"
   source address="192.0.2.0/24"
   destination address="192.0.2.0/24"
   port port="8600-8630" protocol="tcp"
   accept'
```

```
$ sudo firewall-cmd --permanent --add-rich-rule='
   rule family="ipv4"
   source address="192.0.2.0/24"
   destination address="192.0.2.0/24"
   port port="8640" protocol="tcp"
   accept'
```

```
$ sudo firewall-cmd --permanent --add-rich-rule='
   rule family="ipv4"
   source address="192.0.2.0/24"
   destination address="192.0.2.0/24"
   port port="8700" protocol="tcp"
   accept'
```

```
$ sudo firewall-cmd --permanent --add-rich-rule='
   rule family="ipv4"
   source address="192.0.2.0/24"
   destination address="192.0.2.0/24"
   port port="8800" protocol="tcp"
   accept'
```

4. Reload the runtime configuration:

```
$ sudo firewall-cmd --reload
```

Configure UFW (Ubuntu)

Configure UFW for Enterprise ColumnStore on Ubuntu:

1. Check if the UFW service is running:

```
$ sudo ufw status verbose
```

2. If the UFW service was stopped to perform the installation, start it now:

```
$ sudo ufw enable
```

3. Open up the relevant ports using ufw.

For example, if your cluster nodes are in the 192.0.2.0/24 subnet in the range 192.0.2.1 - 192.0.2.3:

```
$ sudo ufw allow from 192.0.2.0/24 to 192.0.2.3 port 3306 proto tcp

$ sudo ufw allow from 192.0.2.0/24 to 192.0.2.3 port 8600:8630 proto tcp

$ sudo ufw allow from 192.0.2.0/24 to 192.0.2.3 port 8640 proto tcp

$ sudo ufw allow from 192.0.2.0/24 to 192.0.2.3 port 8700 proto tcp

$ sudo ufw allow from 192.0.2.0/24 to 192.0.2.3 port 8800 proto tcp
```

4. Reload the runtime configuration:

```
$ sudo ufw reload
```

Next Step

Navigation in the procedure “Deploy ColumnStore Object Storage Topology”:

This page was **step 4 of 9**.

Next: Step 5: Test MariaDB Enterprise Server.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 5: Test MariaDB Enterprise Server

Overview

This page details step 5 of the 9-step procedure “Deploy ColumnStore Object Storage Topology”.

This step tests MariaDB Enterprise Server and MariaDB Enterprise ColumnStore 23.10.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Test S3 Connection

MariaDB Enterprise ColumnStore 23.10 includes a `testS3Connection` command to test the S3 configuration, permissions, and connectivity.

This action is performed **on each Enterprise ColumnStore node**.

Test the S3 configuration by executing the following:

```
$ sudo testS3Connection
```

```
StorageManager[26887]: Using the config file found at /etc/columnstore/storagemanager.cnf
StorageManager[26887]: S3Storage: S3 connectivity & permissions are OK
S3 Storage Manager Configuration OK
```

If the `testS3Connection` command does not return `OK`, investigate the S3 configuration.

Test Enterprise Server Service

Use Systemd to test whether the MariaDB Enterprise Server service is running.

This action is performed **on each Enterprise ColumnStore node**.

Check if the MariaDB Enterprise Server service is running by executing the following:

```
$ systemctl status mariadb
```

If the service is not running on any node, start the service by executing the following on that node:

```
$ sudo systemctl start mariadb
```

Test Local Client Connections

Use MariaDB Client to test the local connection to the Enterprise Server node.

This action is performed on each Enterprise ColumnStore node:

```
$ sudo mariadb
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 38
Server version: 11.4.5-3-MariaDB-Enterprise MariaDB Enterprise Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]>
```

The `sudo` command is used here to connect to the Enterprise Server node using the root@localhost user account, which authenticates using the unix_socket authentication plugin. Other user accounts can be used by specifying the –user and –password command-line options.

Test ColumnStore Storage Engine Plugin

Query the information_schema.PLUGINS table to confirm that the ColumnStore storage engine is loaded.

This action is performed on each Enterprise ColumnStore node.

Execute the following query:

```
SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM information_schema.PLUGINS
WHERE PLUGIN_LIBRARY LIKE 'ha_columnstore%';

+---------------------+---------------+
| PLUGIN_NAME         | PLUGIN_STATUS |
+---------------------+---------------+
| Columnstore         | ACTIVE        |
| COLUMNSTORE_COLUMNS | ACTIVE        |
| COLUMNSTORE_TABLES  | ACTIVE        |
| COLUMNSTORE_FILES   | ACTIVE        |
| COLUMNSTORE_EXTENTS | ACTIVE        |
+---------------------+---------------+
```

The `PLUGIN_STATUS` column for each ColumnStore-related plugin should contain ACTIVE.

Test CMAPI Service

Use Systemd to test whether the CMAPI service is running.

This action is performed on each Enterprise ColumnStore node.

Check if the CMAPI service is running by executing the following:

```
$ systemctl status mariadb-columnstore-cmapi
```

If the service is not running on any node, start the service by executing the following on that node:

```
$ sudo systemctl start mariadb-columnstore-cmapi
```

Test ColumnStore Status

Use CMAPI to request the ColumnStore status. The API key needs to be provided as part of the `X-API-key` HTML header.

This action is performed with the CMAPI service on the primary server.

Check the ColumnStore status using curl by executing the following:

```
$ curl -k -s https://mcs1:8640/cmapi/0.4.0/cluster/status \
   --header 'Content-Type:application/json' \
   --header 'x-api-key:93816fa66cc2d8c224e62275bd4f248234dd4947b68d4af2b29671dd7d5532dd' \
   | jq .

```

Test DDL

Use MariaDB Client to test DDL.

1. On the primary server, use the MariaDB Client to connect to the node:

```
$ sudo mariadb
```

2. Create a test database and ColumnStore table:

```
CREATE DATABASE IF NOT EXISTS test;

CREATE TABLE IF NOT EXISTS test.contacts (
   first_name VARCHAR(50),
   last_name VARCHAR(50),
   email VARCHAR(100)
) ENGINE = ColumnStore;
```

3. On each replica server, use the MariaDB Client to connect to the node:

```
$ sudo mariadb
```

4. Confirm that the database and table exist:

```
SHOW CREATE TABLE test.contacts\G;
```

If the database or table do not exist on any node, then check the replication configuration.

Test DML

Use MariaDB Client to test DML.

1. On the primary server, use the MariaDB Client to connect to the node:

```
$ sudo mariadb
```

2. Insert sample data into the table created in the DDL test:

```
INSERT INTO test.contacts (first_name, last_name, email)
   VALUES
   ("Kai", "Devi", "kai.devi@example.com"),
   ("Lee", "Wang", "lee.wang@example.com");
```

3. On each replica server, use the MariaDB Client to connect to the node:

```
$ sudo mariadb
```

4. Execute a SELECT query to retrieve the data:

```
SELECT * FROM test.contacts;

+------------+-----------+----------------------+
| first_name | last_name | email                |
+------------+-----------+----------------------+
| Kai        | Devi      | kai.devi@example.com |
| Lee        | Wang      | lee.wang@example.com |
+------------+-----------+----------------------+
```

If the data is not returned on any node, check the ColumnStore status and the storage configuration.

Next Step

Navigation in the procedure 'Deploy ColumnStore Object Storage Topology".

This page was **step 5 of 9**.

Next: Step 6: Install MariaDB MaxScale.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 6: Install MariaDB MaxScale

Overview

This page details step 6 of the 9-step procedure "Deploy ColumnStore Object Storage Topology".

This step installs MariaDB MaxScale 22.08.

ColumnStore Object Storage requires 1 or more MaxScale nodes.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Retrieve Customer Download Token

MariaDB Corporation provides package repositories for `CentOS / RHEL (YUM) and Debian / Ubuntu (APT)`. A download token is required to access the MariaDB Enterprise Repository.

Customer Download Tokens are customer-specific and are available through the MariaDB Customer Portal.

To retrieve the token for your account:

1. Navigate to https://customers.mariadb.com/downloads/token/
2. Log in.
3. Copy the Customer Download Token.

Substitute your token for `CUSTOMER_DOWNLOAD_TOKEN` when configuring the package repositories.

Set Up Repository

1. On the MaxScale node, install the prerequisites for downloading the software from the Web.
   Install on CentOS / RHEL (YUM):

```
$ sudo yum install curl
```

Install on Debian / Ubuntu (APT):

```
$ sudo apt install curl apt-transport-https
```

2. On the MaxScale node, configure package repositories and specify MariaDB MaxScale 22.08:

```
$ curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup

$ echo "${checksum}  mariadb_es_repo_setup" \
       | sha256sum -c -

$ chmod +x mariadb_es_repo_setup

$ sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
      --skip-server \
      --skip-tools \
      --mariadb-maxscale-version="22.08"
```

Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.

Install MaxScale

On the MaxScale node, install MariaDB MaxScale.

Install on CentOS / RHEL (YUM):

```
$ sudo yum install maxscale
```

Install on Debian / Ubuntu (APT):

```
$ sudo apt install maxscale
```

Next Step

Navigation in the procedure “Deploy ColumnStore Object Storage Topology”:

This page was **step 6 of 9**.

Next: Step 7: Start and Configure MariaDB MaxScale.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 7: Start and Configure MariaDB MaxScale

Overview

This page details step 7 of the 9-step procedure "Deploy ColumnStore Object Storage Topology".

This step starts and configures MariaDB MaxScale 22.08.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Replace the Default Configuration File

MariaDB MaxScale installations include a configuration file with some example objects. This configuration file should be replaced.

On the MaxScale node, replace the default `/etc/maxscale.cnf` with the following configuration:

```
[maxscale]
threads          = auto
admin_host       = 0.0.0.0
admin_secure_gui = false
```

For additional information, see "Global Parameters".

Restart MaxScale

On the MaxScale node, restart the MaxScale service to ensure that MaxScale picks up the new configuration:

```
$ sudo systemctl restart maxscale
```

For additional information, see "Start and Stop Services".

Configure Server Objects

On the MaxScale node, use maxctrl create to create a server object for each Enterprise ColumnStore node:

```
$ maxctrl create server mcs1 192.0.2.101
```

```
$ maxctrl create server mcs2 192.0.2.102
```

```
$ maxctrl create server mcs3 192.0.2.103
```

Configure MariaDB Monitor

MaxScale uses monitors to retrieve additional information from the servers. This information is used by other services in filtering and routing connections based on the current state of the node. For MariaDB Enterprise ColumnStore, use the MariaDB Monitor (mariadbmon).

On the MaxScale node, use maxctrl create monitor to create a MariaDB Monitor:

```
$ maxctrl create monitor columnstore_monitor mariadbmon \
     user=mxs \
     password='MAXSCALE_USER_PASSWORD' \
     replication_user=repl \
     replication_password='REPLICATION_USER_PASSWORD' \
     --servers mcs1 mcs2 mcs3
```

In this example:

- `columnstore_monitor` is an arbitrary name that is used to identify the new monitor.

- `mariadbmon` is the name of the module that implements the MariaDB Monitor.
- `user=MAXSCALE_USER` sets the user parameter to the database user account that MaxScale uses to monitor the ColumnStore nodes.
- `password='MAXSCALE_USER_PASSWORD'` sets the password parameter to the password used by the database user account that MaxScale uses to monitor the ColumnStore nodes.
- `replication_user=REPLICATION_USER` sets the replication_user parameter to the database user account that MaxScale uses to setup replication.
- `replication_password='REPLICATION_USER_PASSWORD'` sets the replication_password parameter to the password used by the database user account that MaxScale uses to setup replication.
- `--servers` sets the servers parameter to the set of nodes that MaxScale should monitor. All non-option arguments after `--servers` are interpreted as server names.
- Other Module Parameters supported by mariadbmon in MaxScale 22.08 can also be specified.

Choose a MaxScale Router

Routers control how MaxScale balances the load between Enterprise ColumnStore nodes. Each router uses a different approach to routing queries. Consider the specific use case of your application and database load and select the router that best suits your needs.

Router	Configuration Procedure	Description
Read Connection (readconnroute)	Configure Read Connection Router	**Connection-based load balancing** • Routes connections to Enterprise ColumnStore nodes designated as replica servers for a read-only pool • Routes connections to an Enterprise ColumnStore node designated as the primary server for a read-write pool.|
Read/Write Split (readwritesplit)	Configure Read/Write Split	**Query-based load balancing** • Routes write queries to an Enterprise ColumnStore node designated as the primary server • Routes read queries to Enterprise ColumnStore node designated as replica servers • Automatically reconnects after node failures • Automatically replays transactions after node failures • Optionally enforces causal reads|

Configure Read Connection Router

Use MaxScale Read Connection Router (readconnroute) to route connections to replica servers for a read-only pool.

On the MaxScale node, use maxctrl create service to create a router:

```
$ maxctrl create service connection_router_service readconnroute \
     user=mxs \
     password='MAXSCALE_USER_PASSWORD' \
     router_options=slave \
     --servers mcs1 mcs2 mcs3
```

In this example:

- `connection_router_service` is an arbitrary name that is used to identify the new service.
- readconnroute is the name of the module that implements the Read Connection Router.

- `user=MAXSCALE_USER` sets the user parameter to the database user account that MaxScale uses to connect to the ColumnStore nodes.
- `password=MAXSCALE_USER_PASSWORD` sets the password parameter to the password used by the database user account that MaxScale uses to connect to the ColumnStore nodes.
- `router_options=slave` sets the `router_options` parameter to slave, so that MaxScale only routes connections to the replica nodes.
- `--servers` sets the servers parameter to the set of nodes to which MaxScale should route connections. All non-option arguments after `--servers` are interpreted as server names.
- Other Module Parameters supported by `readconnroute` in MaxScale 22.08 can also be specified.

Configure Listener for the Read Connection Router

These instructions reference TCP port 3308. You can use a different TCP port. The TCP port used must not be bound by any other listener.

On the MaxScale node, use the maxctrl create listener command to configure MaxScale to use a listener for the Read Connection Router (readconnroute):

```
$ maxctrl create listener connection_router_service connection_router_listener 3308 \
     protocol=MariaDBClient
```

In this example:

- `connection_router_service` is the name of the `readconnroute` service that was previously created.
- `connection_router_listener` is an arbitrary name that is used to identify the new listener.
- 3308 is the TCP port.
- `protocol=MariaDBClient` sets the protocol parameter.
- Other Module Parameters supported by listeners in MaxScale 22.08 can also be specified.

Configure Read/Write Split Router for Queries

MaxScale Read/Write Split Router (readwritesplit) performs query-based load balancing. The router routes write queries to the primary and read queries to the replicas.

On the MaxScale node, use the maxctrl create service command to configure MaxScale to use the Read/Write Split Router (readwritesplit):

```
$ maxctrl create service query_router_service readwritesplit  \
     user=mxs \
     password='MAXSCALE_USER_PASSWORD' \
     --servers mcs1 mcs2 mcs3
```

In this example:

- `query_router_service` is an arbitrary name that is used to identify the new service.
- `readwritesplit` is the name of the module that implements the Read/Write Split Router.
- `user=MAXSCALE_USER` sets the user parameter to the database user account that MaxScale uses to connect to the ColumnStore nodes.
- `password=MAXSCALE_USER_PASSWORD` sets the password parameter to the password used by the database user account that MaxScale uses to connect to the ColumnStore nodes.
- `--servers` sets the servers parameter to the set of nodes to which MaxScale should route queries. All non-option arguments after `--servers` are interpreted as server names.
- Other Module Parameters supported by `readwritesplit` in MaxScale 22.08 can also be specified.

Configure a Listener for the Read/Write Split Router

These instructions reference TCP port 3307. You can use a different TCP port. The TCP port used must not be bound by any other listener.

On the MaxScale node, use the maxctrl create listener command to configure MaxScale to use a listener for the Read/Write Split Router (readwritesplit):

```
$ maxctrl create listener query_router_service query_router_listener 3307 \
     protocol=MariaDBClient
```

In this example:

- `query_router_service` is the name of the readwritesplit service that was previously created.
- `query_router_listener` is an arbitrary name that is used to identify the new listener.
- 3307 is the TCP port.
- `protocol=MariaDBClient` sets the protocol parameter.
- Other Module Parameters supported by listeners in MaxScale 22.08 can also be specified.

Start Services

To start the services and monitors, on the MaxScale node use maxctrl start services:

```
$ maxctrl start services
```

Next Step

Navigation in the procedure “Deploy ColumnStore Object Storage Topology”:

This page was **step 7 of 9**.

Next: Step 8: Test MariaDB MaxScale

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 8: Test MariaDB MaxScale

Overview

This page details step 8 of the 9-step procedure “Deploy ColumnStore Object Storage Topology”.

This step tests MariaDB MaxScale 22.08.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Check Global Configuration

Use maxctrl show maxscale command to view the global MaxScale configuration.

This action is performed **on the MaxScale node**:

```
$ maxctrl show maxscale
```

```

```

Output should align to the global MaxScale configuration in the new configuration file you created.

Check Server Configuration

Use the maxctrl list servers and maxctrl show server commands to view the configured server objects.

This action is performed **on the MaxScale node**:

1. Obtain the full list of servers objects:

```
$ maxctrl list servers
```

```
┌────────┬─────────────┬──────┬─────────────┬─────────────────┬──────────┐
| Server | Address     | Port | Connections | State           | GTID     |
├────────┼─────────────┼──────┼─────────────┼─────────────────┼──────────┤
| mcs1   | 192.0.2.1   | 3306 | 1           | Master, Running | 0-1-25 |
├────────┼─────────────┼──────┼─────────────┼─────────────────┼──────────┤
| mcs2   | 192.0.2.2   | 3306 | 1           | Slave, Running  | 0-1-25 |
├────────┼─────────────┼──────┼─────────────┼─────────────────┼──────────┤
| mcs3   | 192.0.2.3   | 3306 | 1           | Slave, Running  | 0-1-25 |
└────────┴─────────────┴──────┴─────────────┴─────────────────┴──────────┘
```

For each server object, view the configuration:

```
$ maxctrl show server mcs1
```

```
┌──────────────────┬──────────────────────────────────────────────┐

Output should align to the Server Object configuration you performed.

Check Monitor Configuration

Use the maxctrl list monitors and maxctrl show monitor commands to view the configured monitors.

This action is performed on the MaxScale node:

1. Obtain the full list of monitors:

```
$ maxctrl list monitors
```

```
┌─────────────────────┬─────────┬──────────────────┐
│ Monitor             │ State   │ Servers          │
├─────────────────────┼─────────┼──────────────────┤
│ columnstore_monitor │ Running │ mcs1, mcs2, mcs3 │
└─────────────────────┴─────────┴──────────────────┘
```

2. For each monitor, view the monitor configuration:

```
$ maxctrl show monitor columnstore_monitor
```

```
┌─────────────────────┬──────────────────────────────────────────┐
│ Monitor             │ columnstore_monitor                      │
├─────────────────────┼──────────────────────────────────────────┤
│ Module              │ mariadbmon                               │
├─────────────────────┼──────────────────────────────────────────┤
│ State               │ Running                                  │
├─────────────────────┼──────────────────────────────────────────┤
│ Servers             │ mcs1                                     │

└──────────────────────┴─────────────────────────────────────────────────────────────────────┘
```

Output should align to the Read Connection Router (readconnroute) or Read/Write Split Router (readwritesplit) configuration you performed.

Test Application User

Applications should use a dedicated user account. The user account must be created on the primary server.

When users connect to MaxScale, MaxScale authenticates the user connection before routing it to an Enterprise Server node. Enterprise Server authenticates the connection as originating from the IP address of the MaxScale node.

The application users must have one user account with the host IP address of the application server and a second user account with the host IP address of the MaxScale node.

The requirement of a duplicate user account can be avoided by enabling the `proxy_protocol` parameter for MaxScale and the proxy_protocol_networks for Enterprise Server.

Create a User to Connect from MaxScale

This action is performed on the primary Enterprise ColumnStore node:

1. Connect to the primary Enterprise ColumnStore node:

```
$ sudo mariadb
```

2. Create the database user account for your MaxScale node:

```
CREATE USER 'app_user'@'192.0.2.10' IDENTIFIED BY 'app_user_passwd';
```

Replace 192.0.2.10 with the relevant IP address specification for your MaxScale node.

Passwords should meet your organization's password policies.

3. Grant the privileges required by your application to the database user account for your MaxScale node:

```
GRANT ALL ON test.* TO 'app_user'@'192.0.2.10';
```

The privileges shown are designed to allow the tests in the subsequent sections to work. The user account for your production application may require different privileges.

Create a User to Connect from the Application Server

This action is performed on the primary Enterprise ColumnStore node:

1. Create the database user account for your application server:

```
CREATE USER 'app_user'@'192.0.2.11' IDENTIFIED BY 'app_user_passwd';
```

Replace 192.0.2.11 with the relevant IP address specification for your application server.

Passwords should meet your organization's password policies.

2. Grant the privileges required by your application to the d database user account for your application server:

```
GRANT ALL ON test.* TO 'app_user'@'192.0.2.11';
```

The privileges shown are designed to allow the tests in the subsequent sections to work. The user account for your production application may require different privileges.

Test Connection with Application User

To test the connection, use the MariaDB Client from your application server to connect to an Enterprise ColumnStore node through MaxScale.

This action is performed **on a client connected to the MaxScale node**:

```
$ mariadb --host 192.0.2.10 --port 3307
      --user app_user --password
```

Test Connection with Read Connection Router

If you configured the Read Connection Router, confirm that MaxScale routes connections to the replica servers.

On the MaxScale node, use the maxctrl list listeners command to view the available listeners and ports:

```
$ maxctrl list listeners
```

```
┌──────────────────────────┬──────┬──────┬─────────┬──────────────────────────┐
│ Name                     │ Port │ Host │ State   │ Service                  │
├──────────────────────────┼──────┼──────┼─────────┼──────────────────────────┤
│ connection_router_listener │ 3308 │ ::   │ Running │ connection_router_service │
├──────────────────────────┼──────┼──────┼─────────┼──────────────────────────┤
│ query_router_listener    │ 3307 │ ::   │ Running │ query_router_service     │
└──────────────────────────┴──────┴──────┴─────────┴──────────────────────────┘
```

2. Open multiple terminals connected to your application server, in each, use MariaDB Client to connect to the listener port for the Read Connection Router (in the example, 3308):

```
$ mariadb --host 192.0.2.10 --port 3308 \
      --user app_user --password
```

Use the application user credentials you created for the `--user and --password` options.

3. In each terminal, query the hostname and server_id system variable and option to identify to which you're connected:

```
SELECT @@global.hostname, @@global.server_id;

+-------------------+--------------------+
| @@global.hostname | @@global.server_id |
+-------------------+--------------------+
|              mcs2 |                  2 |
+-------------------+--------------------+
```

Different terminals should return different values since MaxScale routes the connections to different nodes.

Since the router was configured with the slave router option, the Read Connection Router only routes connections to replica servers.

Test Write Queries with Read/Write Split Router

If you configured the Read/Write Split Router, confirm that MaxScale routes write queries on this router to the primary Enterprise ColumnStore node.

on the MaxScale node, use the maxctrl list listeners command to view the available listeners and ports:

```
$ maxctrl list listeners
```

```
┌──────────────────────────┬──────┬──────┬─────────┬──────────────────────────┐
| Name                     | Port | Host | State   | Service                  |
├──────────────────────────┼──────┼──────┼─────────┼──────────────────────────┤
| connection_router_listener | 3308 | ::   | Running | connection_router_service |
├──────────────────────────┼──────┼──────┼─────────┼──────────────────────────┤
| query_router_listener    | 3307 | ::   | Running | query_router_service     |
└──────────────────────────┴──────┴──────┴─────────┴──────────────────────────┘
```

2. Open multiple terminals connected to your application server, in each, use MariaDB Client to connect to the listener port for the Read/Write Split Router (in the example, 3307):

```
$ mariadb --host 192.0.2.10 --port 3307 \
      --user app_user --password
```

Use the application user credentials you created for the `--user and --password` options.

3. In one terminal, create the test table:

```
CREATE TABLE test.load_balancing_test (
   id INT PRIMARY KEY AUTO_INCREMENT,
   hostname VARCHAR(256),
   server_id INT
);
```

4. In each terminal, issue an insert.md statement to add a row to the example table with the values of the hostname and server_id system variable and option:

```
INSERT INTO test.load_balancing_test (hostname, server_id)
VALUES (@@global.hostname, @@global.server_id);
```

5. In one terminal, issue a SELECT statement to query the results:

```
SELECT * FROM test.load_balancing_test;
```

```
+----+----------+-----------+
| id | hostname | server_id |
+----+----------+-----------+
|  1 | mcs1     |         1 |
|  2 | mcs1     |         1 |
|  3 | mcs1     |         1 |
+----+----------+-----------+
```

While MaxScale is handling multiple connections from different terminals, it routed all connections to the current primary Enterprise ColumnStore node, which in the example is `mcs1#.`

Test Read Queries with Read/Write Split Router

If you configured the Read/Write Split Router (readwritesplit), confirm that MaxScale routes read queries on this router to replica servers.

1. On the MaxScale node, use the maxctrl list listeners command to view the available listeners and ports:

```
$ maxctrl list listeners
```

```
┌──────────────────────────┬──────┬──────┬─────────┬──────────────────────────┐
│ Name                     │ Port │ Host │ State   │ Service                  │
├──────────────────────────┼──────┼──────┼─────────┼──────────────────────────┤
│ connection_router_listener │ 3308 │ ::   │ Running │ connection_router_service │
├──────────────────────────┼──────┼──────┼─────────┼──────────────────────────┤
│ query_router_listener    │ 3307 │ ::   │ Running │ query_router_service     │
└──────────────────────────┴──────┴──────┴─────────┴──────────────────────────┘
```

2. In a terminal connected to your application server, use MariaDB Client to connect to the listener port for the Read/Write Split Router (readwritesplit) (in the example, 3307):

```
$ mariadb --host 192.0.2.10 --port 3307 \
      --user app_user --password
```

Use the application user credentials you created for the –user and –password options.

3. Query the hostname and server_id to identify which server MaxScale routed you to.

```
SELECT @@global.hostname, @@global.server_id;
```

```
+-------------------+--------------------+
| @@global.hostname | @@global.server_id |
+-------------------+--------------------+
|              mcs2 |                  2 |
+-------------------+--------------------+
```

4. Resend the query:

```
SELECT @@global.hostname, @@global.server_id;
```

```
+-------------------+--------------------+
| @@global.hostname | @@global.server_id |
+-------------------+--------------------+
|              mcs3 |                  3 |
+-------------------+--------------------+
```

Confirm that MaxScale routes the SELECT statements to different replica servers.

For more information on different routing criteria, see slave_selection_criteria

Next Step

Navigation in the procedure “Deploy ColumnStore Object Storage Topology”:

This page was **step 8 of 9**.

Next: Step 9: Import Data

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 9: Import Data

Overview

This page details step 9 of the 9-step procedure "Deploy ColumnStore Object Storage Topology".

This step bulk imports data to Enterprise ColumnStore.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Import the Schema

Before data can be imported into the tables, create a matching schema.

On the primary server, create the schema:

1. For each database that you are importing, create the database with the CREATE DATABASE statement:

```
CREATE DATABASE inventory;
```

2. For each table that you are importing, create the table with the CREATE TABLE statement:

```
CREATE TABLE inventory.products (
   product_name VARCHAR(11) NOT NULL DEFAULT '',
   supplier VARCHAR(128) NOT NULL DEFAULT '',
   quantity VARCHAR(128) NOT NULL DEFAULT '',
   unit_cost VARCHAR(128) NOT NULL DEFAULT ''
) ENGINE=Columnstore DEFAULT CHARSET=utf8;
```

Import the Data

Enterprise ColumnStore supports multiple methods to import data into ColumnStore tables.

Interface	Method	Benefits
Shell	cpimport	• SQL access is not required
SQL	LOAD DATA INFILE	• Shell access is not required
Remote Database	Remote Database Import	• Use normal database client • Avoid dumping data to intermediate filed

cpimport

MariaDB Enterprise ColumnStore includes cpimport, which is a command-line utility designed to efficiently load data in bulk. Alternative methods are available.

To import your data from a TSV (tab-separated values) file, on the primary server run cpimport:

```
$ sudo cpimport -s '\t' inventory products /tmp/inventory-products.tsv
```

LOAD DATA INFILE

When data is loaded with the LOAD DATA INFILE statement, MariaDB Enterprise ColumnStore loads the data using cpimport, which is a command-line utility designed to efficiently load data in bulk. Alternative methods are available.

To import your data from a TSV (tab-separated values) file, on the primary server use LOAD DATA INFILE statement:

```
LOAD DATA INFILE '/tmp/inventory-products.tsv'
INTO TABLE inventory.products;
```

Import from Remote Database

MariaDB Enterprise ColumnStore can also import data directly from a remote database. A simple method is to query the table using the SELECT statement, and then pipe the results into cpimport, which is a command-line utility that is designed to efficiently load data in bulk. Alternative methods are available.

To import your data from a remote MariaDB database:

```
$ mariadb --quick \
   --skip-column-names \
   --execute="SELECT * FROM inventory.products" \
   | cpimport -s '\t' inventory products
```

Next Step

Navigation in the procedure “Deploy ColumnStore Object Storage Topology”:

This page was **step 9 of 9**.

This procedure is complete.

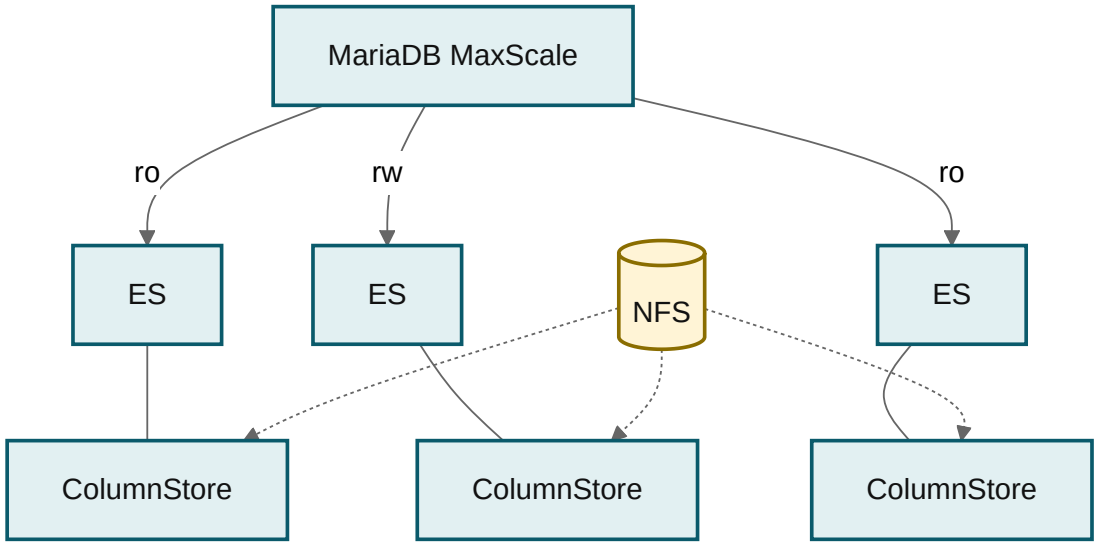
ColumnStore Shared Local Storage

Overview



MaxScale routes to a three-node ColumnStore cluster sharing NFS storage.

- Enterprise Server 10.5
- Enterprise Server 10.6
- Enterprise Server 11.4

Columnar storage engine with S3-compatible object storage

- Highly available
- Automatic failover via MaxScale and CMAPI
- Scales reads via MaxScale
- Bulk data import
- Enterprise Server 10.5, Enterprise ColumnStore 5, MaxScale 2.5

- Enterprise Server 10.6, Enterprise ColumnStore 23.02, MaxScale 22.08

This procedure describes the deployment of the ColumnStore Shared Local Storage topology with MariaDB Enterprise Server 10.5, MariaDB Enterprise ColumnStore 5, and MariaDB MaxScale 2.5.

MariaDB Enterprise ColumnStore 5 is a columnar storage engine for MariaDB Enterprise Server 10.5. Enterprise ColumnStore is suitable for Online Analytical Processing (OLAP) workloads.

This procedure has 9 steps, which are executed in sequence.

This procedure represents basic product capability and deploys 3 Enterprise ColumnStore nodes and 1 MaxScale node.

This page provides an overview of the topology, requirements, and deployment procedures.

Please read and understand this procedure before executing.

Procedure Steps

Step	Description
Step 1	Prepare ColumnStore Nodes
Step 2	Configure Shared Local Storage
Step 3	Install MariaDB Enterprise Server
Step 4	Start and Configure MariaDB Enterprise Server
Step 5	Test MariaDB Enterprise Server
Step 6	Install MariaDB MaxScale
Step 7	Start and Configure MariaDB MaxScale
Step 8	Test MariaDB MaxScale
Step 9	Import Data

Support

Customers can obtain support by submitting a support case.

Components

The following components are deployed during this procedure:

Component	Function
MariaDB Enterprise Server	Modern SQL RDBMS with high availability, pluggable storage engines, hot online backups, and audit logging.
MariaDB MaxScale	Database proxy that extends the availability, scalability, and security of MariaDB Enterprise Servers

MariaDB Enterprise Server Components

Component	Description
MariaDB Enterprise ColumnStore	• Columnar storage engine • Highly available • Optimized for Online Analytical Processing (OLAP) workloads • Scalable query execution • Cluster Management API (CMAPI) provides a REST API for multi-node administration.

MariaDB MaxScale Components

Component	Description
Listener	Listens for client connections to MaxScale then passes them to the router service

Component	Description
MariaDB Monitor	Tracks changes in the state of MariaDB Enterprise Servers.
Read Connection Router	Routes connections from the listener to any available Enterprise ColumnStore node
Read/Write Split Router	Routes read operations from the listener to any available Enterprise ColumnStore node, and routes write operations from the listener to a specific server that MaxScale uses as the primary server
Server Module	Connection configuration in MaxScale to an Enterprise ColumnStore node

Topology

The MariaDB Enterprise ColumnStore topology with Object Storage delivers production analytics with high availability, fault tolerance, and limitless data storage by leveraging S3-compatible storage.

The topology consists of:

- One or more MaxScale nodes
- An odd number of ColumnStore nodes (minimum of 3) running ES, Enterprise ColumnStore, and CMAPI

The MaxScale nodes:

- Monitor the health and availability of each ColumnStore node using the MariaDB Monitor (mariadbmon)
- Accept client and application connections
- Route queries to ColumnStore nodes using the Read/Write Split Router (readwritesplit)

The ColumnStore nodes:

- Receive queries from MaxScale
- Execute queries
  - Use shared local storage for the Storage Manager directory

Requirements

These requirements are for the ColumnStore Object Storage topology when deployed with MariaDB Enterprise Server 10.5, MariaDB Enterprise ColumnStore 5, and MariaDB MaxScale 2.5.

- Node Count
- Operating System
- Minimum Hardware Requirements
- Recommended Hardware Requirements
- Storage Requirements
- S3-Compatible Object Storage Requirements
- Preferred Object Storage Providers: Cloud
- Preferred Object Storage Providers: Hardware
- Shared Local Storage Directories
- Shared Local Storage Options
- Recommended Storage Options

Node Count

- MaxScale nodes, 1 or more are required.
- Enterprise ColumnStore nodes, 3 or more are required for high availability. You should always have an odd number of nodes in a multi-node ColumnStore deployment to avoid split brain scenarios.

Operating System

In alignment to the enterprise lifecycle, the ColumnStore Object Storage topology with MariaDB Enterprise Server 10.5, MariaDB Enterprise ColumnStore 5, and MariaDB MaxScale 2.5 is provided for:

- CentOS Linux 7 (x86_64)
- Debian 10 (x86_64)
- Red Hat Enterprise Linux 7 (x86_64)
- Red Hat Enterprise Linux 8 (x86_64)
- Ubuntu 18.04 LTS (x86_64)
- Ubuntu 20.04 LTS (x86_64)

Minimum Hardware Requirements

MariaDB Enterprise ColumnStore's minimum hardware requirements are not intended for production environments, but the minimum hardware requirements can be appropriate for development and test environments. For production environments, see the recommended hardware requirements instead.

The minimum hardware requirements are:

Component	CPU	Memory
MaxScale node	4+ cores	4+ GB
Enterprise ColumnStore node	4+ cores	4+ GB

MariaDB Enterprise ColumnStore will refuse to start if the system has less than 3 GB of memory.

If Enterprise ColumnStore is started on a system with less memory, the following error message will be written to the ColumnStore system log called crit.log:

```
Apr 30 21:54:35 a1ebc96a2519 PrimProc[1004]: 35.668435 |0|0|0| C 28 CAL0000: Error total memory available
is less than 3GB.
```

And the following error message will be raised to the client:

```
ERROR 1815 (HY000): Internal error: System is not ready yet. Please try again.
```

Recommended Hardware Requirements

MariaDB Enterprise ColumnStore's recommended hardware requirements are intended for production analytics.

The recommended hardware requirements are:

Component	CPU	Memory
MaxScale node	8+ cores	16+ GB
Enterprise ColumnStore node	64+ cores	128+ GB

Storage Requirements

The ColumnStore Object Storage topology requires the following storage types:

Storage Type	Description
Shared Local Storage	The ColumnStore Object Storage topology uses shared local storage for the Storage Manager directory to store metadata.

Shared Local Storage Directories

The ColumnStore Object Storage topology uses shared local storage for the Storage Manager directory to store metadata.

The Storage Manager directory is located at the following path by default:

- `/var/lib/columnstore/storagemanager`

Shared Local Storage Options

The most common shared local storage options for the ColumnStore Object Storage topology are:

Shared Local Storage	Common Usage	Description
EBS (Elastic Block Store) Multi-Attach	AWS	• EBS is a high-performance block-storage service for AWS (Amazon Web Services). • EBS Multi-Attach allows an EBS volume to be attached to multiple instances in AWS. Only clustered file systems, such as GFS2, are supported. • For deployments in AWS, EBS Multi-Attach is a recommended option for the Storage Manager directory, and Amazon S3 storage is the recommended option for data.
EFS (Elastic File System)	AWS	• EFS is a scalable, elastic, cloud-native NFS file system for AWS (Amazon Web Services). • For deployments in AWS, EFS is a recommended option for the Storage Manager directory, and Amazon S3 storage is the recommended option for data. EFS is a scalable, elastic, cloud-native NFS file system for AWS (Amazon Web Services).
Filestore	GCP	• Filestore is high-performance, fully managed storage for GCP (Google Cloud Platform). • For deployments in GCP, Filestore is the recommended option for the Storage Manager directory, and Google Object Storage (S3-compatible) is the recommended option for data.
GlusterFS	On-premises	• GlusterFS is a distributed file system. • GlusterFS supports replication and failover.
NFS (Network File System)	On-premises	• NFS is a distributed file system. • If NFS is used, the storage should be mounted with the sync option to ensure that each node flushes its changes immediately. • For on-premises deployments, NFS is the recommended option for the Storage Manager directory, and any S3-compatible storage is the recommended option for data.

Enterprise ColumnStore Management with CMAPI

Enterprise ColumnStore's CMAPI (Cluster Management API) is a REST API that can be used to manage a multi-node Enterprise ColumnStore cluster.

Many tools are capable of interacting with REST APIs. For example, the curl utility could be used to make REST API calls from the command-line.

Many programming languages also have libraries for interacting with REST APIs.

The examples below show how to use the CMAPI with curl.

URL Endpoint Format for REST API

```
https://{server}:{port}/cmapi/{version}/{route}/{command}
```

For example:

- shutdown
- start
- status

Required Request Headers

- `'x-api-key'`: '93816fa66cc2d8c224e62275bd4f248234dd4947b68d4af2b29671dd7d5532dd'
- `'Content-Type'`: 'application/json'

x-api-key can be set to any value of your choice during the first call to the server. Subsequent connections will require this same key.

Get Status

```
$ curl -k -s https://mcs1:8640/cmapi/0.4.0/cluster/status \
      --header 'Content-Type:application/json' \
      --header 'x-api-key:93816fa66cc2d8c224e62275bd4f248234dd4947b68d4af2b29671dd7d5532dd' \
      | jq .
```

Start Cluster

```
$ curl -k -s -X PUT https://mcs1:8640/cmapi/0.4.0/cluster/start \
      --header 'Content-Type:application/json' \
      --header 'x-api-key:93816fa66cc2d8c224e62275bd4f248234dd4947b68d4af2b29671dd7d5532dd' \
      --data '{"timeout":20}' \
      | jq .
```

Stop Cluster

```
$ curl -k -s -X PUT https://mcs1:8640/cmapi/0.4.0/cluster/shutdown \
      --header 'Content-Type:application/json' \
      --header 'x-api-key:93816fa66cc2d8c224e62275bd4f248234dd4947b68d4af2b29671dd7d5532dd' \
      --data '{"timeout":20}' \
      | jq .
```

Add Node

```
$ curl -k -s -X PUT https://mcs1:8640/cmapi/0.4.0/cluster/node \
      --header 'Content-Type:application/json' \
      --header 'x-api-key:93816fa66cc2d8c224e62275bd4f248234dd4947b68d4af2b29671dd7d5532dd' \
      --data '{"timeout":20, "node": "192.0.2.2"}' \
      | jq .
```

Remove Node

```
$ curl -k -s -X DELETE https://mcs1:8640/cmapi/0.4.0/cluster/node \
      --header 'Content-Type:application/json' \
      --header 'x-api-key:93816fa66cc2d8c224e62275bd4f248234dd4947b68d4af2b29671dd7d5532dd' \
      --data '{"timeout":20, "node": "192.0.2.2"}' \
      | jq .
```

Quick Reference

MariaDB Enterprise Server Configuration Management

Method	Description
Configuration File	Configuration files (such as /etc/my.cnf) can be used to set system-variables and options. The server must be restarted to apply changes made to configuration files.
Command-line	The server can be started with command-line options that set system-variables and options.
SQL	Users can set system-variables that support dynamic changes on-the-fly using the SET statement.

MariaDB Enterprise Server packages are configured to read configuration files from different paths, depending on the operating system. Making custom changes to Enterprise Server default configuration files is not recommended because custom changes may be overwritten by other default configuration files that are loaded later.

To ensure that your custom changes will be read last, create a custom configuration file with the z- prefix in one of the include directories.

Distribution	Example Configuration File Path
• CentOS • Red Hat Enterprise Linux (RHEL)	/etc/my.cnf.d/z-custom-mariadb.cnf
• Debian • Ubuntu	/etc/mysql/mariadb.conf.d/z-custom-mariadb.cnf

MariaDB Enterprise Server Service Management

The systemctl command is used to start and stop the MariaDB Enterprise Server service.

Operation	Command
Start	`sudo systemctl start mariadb`
Stop	`sudo systemctl stop mariadb`
Restart	`sudo systemctl restart mariadb`
Enable during startup	`sudo systemctl enable mariadb`
Disable during startup	`sudo systemctl disable mariadb`
Status	`sudo systemctl status mariadb`

For additional information, see “Starting and Stopping MariaDB”.

MariaDB Enterprise Server Logs

MariaDB Enterprise Server produces log data that can be helpful in problem diagnosis.

Log filenames and locations may be overridden in the server configuration. The default location of logs is the data directory. The data directory is specified by the datadir system variable.

Log	System Variable/Option	Default Filename
MariaDB Error Log	log_error	`<hostname>.err`
MariaDB Enterprise Audit Log	server_audit_file_path	`server_audit.log`
Slow Query Log	slow_query_log_file	`<hostname>-slow.log`
General Query Log	general_log_file	`<hostname>.log`
Binary Log	log_bin	`<hostname>-bin`

Enterprise ColumnStore Service Management

The systemctl command is used to start and stop the ColumnStore service.

Operation	Command
Start	`sudo systemctl start mariadb-columnstore`
Stop	`sudo systemctl stop mariadb-columnstore`
Restart	`sudo systemctl restart mariadb-columnstore`
Enable during startup	`sudo systemctl enable mariadb-columnstore`

Operation	Command
Disable during startup	`sudo systemctl disable mariadb-columnstore`
Status	`sudo systemctl status mariadb-columnstore`

In the ColumnStore Object Storage topology, the mariadb-columnstore service should not be enabled. The CMAPI service restarts Enterprise ColumnStore as needed, so it does not need to start automatically upon reboot.

Enterprise ColumnStore CMAPI Service Management

The systemctl command is used to start and stop the CMAPI service.

Operation	Command
Start	`sudo systemctl start mariadb-columnstore-cmapi`
Stop	`sudo systemctl stop mariadb-columnstore-cmapi`
Restart	`sudo systemctl restart mariadb-columnstore-cmapi`
Enable during startup	`sudo systemctl enable mariadb-columnstore-cmapi`
Disable during startup	`sudo systemctl disable mariadb-columnstore-cmapi`
Status	`sudo systemctl status mariadb-columnstore-cmapi`

For additional information on endpoints, see “CMAPI”.

MaxScale Configuration Management

MaxScale can be configured using several methods. These methods make use of MaxScale’s REST API.

Method	Benefits
MaxCtrl	Command-line utility to perform administrative tasks through the REST API. See MaxCtrl Commands.
MaxGUI	MaxGUI is a graphical utility that can perform administrative tasks through the REST API.
REST API	The REST API can be used directly. For example, the curl utility could be used to make REST API calls from the command-line. Many programming languages also have libraries to interact with REST APIs.

The procedure on these pages configures MaxScale using MaxCtrl.

MaxScale Service Management

The systemctl command is used to start and stop the MaxScale service.>

Operation	Command
Start	`sudo systemctl start maxscale`
Stop	`sudo systemctl stop maxscale`
Restart	`sudo systemctl restart maxscale`
Enable during startup	`sudo systemctl enable maxscale`
Disable during startup	`sudo systemctl disable maxscale`
Status	`sudo systemctl status maxscale`

For additional information, see “Start and Stop Services”.

Next Step

Navigation in the procedure Shared Local Storage topology

Next: Step 1: Prepare ColumnStore Nodes.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 1: Prepare ColumnStore Nodes

Overview

This page details step 1 of the 9-step procedure "Deploy ColumnStore Shared Local Storage Topology".

This step prepares systems to host MariaDB Enterprise Server and MariaDB Enterprise ColumnStore 23.10.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Optimize Linux Kernel Parameters

MariaDB Enterprise ColumnStore performs best with Linux kernel optimizations.

On each server to host an Enterprise ColumnStore node, optimize the kernel:

1. Set the relevant kernel parameters in a sysctl configuration file. To ensure proper change management, use an Enterprise ColumnStore-specific configuration file.

   Create `a /etc/sysctl.d/90-mariadb-enterprise-columnstore.conf file`:

```
# minimize swapping
vm.swappiness = 1

# Increase the TCP max buffer size
net.core.rmem_max = 16777216
net.core.wmem_max = 16777216

# Increase the TCP buffer limits
# min, default, and max number of bytes to use
net.ipv4.tcp_rmem = 4096 87380 16777216
net.ipv4.tcp_wmem = 4096 65536 16777216

# don't cache ssthresh from previous connection
net.ipv4.tcp_no_metrics_save = 1

# for 1 GigE, increase this to 2500
# for 10 GigE, increase this to 30000
net.core.netdev_max_backlog = 2500
```

2. Use the sysctl command to set the kernel parameters at runtime

```
$ sudo sysctl --load=/etc/sysctl.d/90-mariadb-enterprise-columnstore.conf
```

Temporarily Configure Linux Security Modules (LSM)

The Linux Security Modules (LSM) should be temporarily disabled on each Enterprise ColumnStore node during installation.

The LSM will be configured and re-enabled later in this deployment procedure.

The steps to disable the LSM depend on the specific LSM used by the operating system.

CentOS / RHEL Stop SELinux

SELinux must be set to permissive mode before installing MariaDB Enterprise ColumnStore.

To set SELinux to permissive mode:

1. Set SELinux to permissive mode:

```
$ sudo setenforce permissive
```

2. Set SELinux to permissive mode by setting SELINUX=permissive in /etc/selinux/config.

For example, the file will usually look like this after the change:

```
# This file controls the state of SELinux on the system.
# SELINUX= can take one of these three values:
#     enforcing - SELinux security policy is enforced.
#     permissive - SELinux prints warnings instead of enforcing.
#     disabled - No SELinux policy is loaded.
SELINUX=permissive
# SELINUXTYPE= can take one of three values:
#     targeted - Targeted processes are protected,
#     minimum - Modification of targeted policy. Only selected processes are protected.
#     mls - Multi Level Security protection.
SELINUXTYPE=targeted
```

3. Confirm that SELinux is in permissive mode:

```
$ sudo getenforce
Permissive
```

SELinux will be configured and re-enabled later in this deployment procedure. This configuration is not persistent. If you restart the server before configuring and re-enabling SELinux later in the deployment procedure, you must reset the enforcement to permissive mode.

Debian / Ubuntu AppArmor

AppArmor must be disabled before installing MariaDB Enterprise ColumnStore.

1. Disable AppArmor:

```
$ sudo systemctl disable apparmor
```

2. Reboot the system.
3. Confirm that no AppArmor profiles are loaded using aa-status:

```
$ sudo aa-status
```

```
apparmor module is loaded.
0 profiles are loaded.
0 profiles are in enforce mode.
0 profiles are in complain mode.
0 processes have profiles defined.
0 processes are in enforce mode.
0 processes are in complain mode.
0 processes are unconfined but have a profile defined.
```

AppArmor will be configured and re-enabled later in this deployment procedure.

Temporarily Configure Firewall for Installation

MariaDB Enterprise ColumnStore requires the following TCP ports:

TCP Ports	Description
3306	Port used for MariaDB Client traffic
8600-8630	Port range used for inter-node communication
8640	Port used by CMAPI
8700	Port used for inter-node communication
8800	Port used for inter-node communication

The firewall should be temporarily disabled on each Enterprise ColumnStore node during installation.

The firewall will be configured and re-enabled later in this deployment procedure.

The steps to disable the firewall depend on the specific firewall used by the operating system.

CentOS / RHEL Stop firewalld

1. Check if the firewalld service is running:

```
$ sudo systemctl status firewalld
```

2. If the firewalld service is running, stop it:

```
$ sudo systemctl stop firewalld
```

Firewalld will be configured and re-enabled later in this deployment procedure.

Ubuntu Stop UFW

1. Check if the UFW service is running:

```
$ sudo ufw status verbose
```

2. If the UFW service is running, stop it:

```
$ sudo ufw disable
```

UFW will be configured and re-enabled later in this deployment procedure.

Configure the AWS Security Group

To install Enterprise ColumnStore on Amazon Web Services (AWS), the security group must be modified prior to installation.

Enterprise ColumnStore requires all internal communications to be open between Enterprise ColumnStore nodes. Therefore, the security group should allow all protocols and all ports to be open between the Enterprise ColumnStore nodes and the MaxScale proxy.

Configure Character Encoding

When using MariaDB Enterprise ColumnStore, it is recommended to set the system's locale to UTF-8.

1. On RHEL 8, install additional dependencies:

```
$ sudo yum install glibc-locale-source glibc-langpack-en
```

2. Set the system's locale to en_US.UTF-8 by executing localedef:

```
$ sudo localedef -i en_US -f UTF-8 en_US.UTF-8
```

Configure DNS

MariaDB Enterprise ColumnStore requires all nodes to have host names that are resolvable on all other nodes. If your infrastructure does not configure DNS centrally, you may need to configure static DNS entries in the /etc/hosts file of each server.

On each Enterprise ColumnStore node, edit the /etc/hosts file to map host names to the IP address of each Enterprise ColumnStore node:

```
192.0.2.1     mcs1
192.0.2.2     mcs2
192.0.2.3     mcs3
192.0.2.100   mxs1
```

Replace the IP addresses with the addresses in your own environment.

Next Step

Navigation in the procedure “Deploy ColumnStore Shared Local Storage Topology”.

This page was step 1 of 9.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 2: Configure Shared Local Storage

Overview

This page details step 2 of the 9-step procedure “Deploy ColumnStore Shared Local Storage Topology”.

This step configures shared local storage on systems hosting Enterprise ColumnStore 23.10.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Directories for Shared Local Storage

In a ColumnStore Object Storage topology, MariaDB Enterprise ColumnStore requires the Storage Manager directory to be located on shared local storage.

The Storage Manager directory is at the following path:

- `/var/lib/columnstore/storagemanager`

The N in dataN represents a range of integers that starts at 1 and stops at the number of nodes in the deployment. For example, with a 3-node Enterprise ColumnStore deployment, this would refer to the following directories:

- `/var/lib/columnstore/data1`
- `/var/lib/columnstore/data2`
- `/var/lib/columnstore/data3`

The DB Root directories must be mounted on every ColumnStore node.

Choose a Shared Local Storage Solution

Select a Shared Local Storage solution for the Storage Manager directory:

- EBS (Elastic Block Store) Multi-Attach
- EFS (Elastic File System)
- Filestore
- GlusterFS
- NFS (Network File System)

For additional information, see “Shared Local Storage Options”.

Configure EBS Multi-Attach

EBS is a high-performance block-storage service for AWS (Amazon Web Services). EBS Multi-Attach allows an EBS volume to be attached to multiple instances in AWS. Only clustered file systems, such as GFS2, are supported.

For Enterprise ColumnStore deployments in AWS:

- EBS Multi-Attach is a recommended option for the Storage Manager directory.
- Amazon S3 storage is the recommended option for data.
- Consult the vendor documentation for details on how to configure EBS Multi-Attach.

Configure Elastic File System (EFS)

EFS is a scalable, elastic, cloud-native NFS file system for AWS (Amazon Web Services)

For deployments in AWS:

- EFS is a recommended option for the Storage Manager directory.
- Amazon S3 storage is the recommended option for data.
- Consult the vendor documentation for details on how to configure EFS.

Configure Filestore

Filestore is high-performance, fully managed storage for GCP (Google Cloud Platform).

For Enterprise ColumnStore deployments in GCP:

- Filestore is the recommended option for the Storage Manager directory.
- Google Object Storage (S3-compatible) is the recommended option for data.
- Consult the vendor documentation for details on how to configure Filestore.

Configure GlusterFS

GlusterFS is a distributed file system.

GlusterFS is a shared local storage option, but it is not one of the recommended options.

For more information, see “Recommended Storage Options”.

Install GlusterFS

On each Enterprise ColumnStore node, install GlusterFS.

Install on CentOS / RHEL 8 (YUM):

```
$ sudo yum install --enablerepo=PowerTools glusterfs-server
```

Install on CentOS / RHEL 7 (YUM):

```
$ sudo yum install centos-release-gluster
$ sudo yum install glusterfs-server
```

Install on Debian (APT):

```
$ wget -O - https://download.gluster.org/pub/gluster/glusterfs/LATEST/rsa.pub | apt-key add -

$ DEBID=$(grep 'VERSION_ID=' /etc/os-release | cut -d '=' -f 2 | tr -d '"')
$ DEBVER=$(grep 'VERSION=' /etc/os-release | grep -Eo '[a-z]+')
$ DEBARCH=$(dpkg --print-architecture)
$ echo deb https://download.gluster.org/pub/gluster/glusterfs/LATEST/Debian/${DEBID}/${DEBARCH}/apt
${DEBVER} main > /etc/apt/sources.list.d/gluster.list
```

```
$ sudo apt update
```

```
$ sudo apt install glusterfs-server
```

Install on Ubuntu (APT):

```
$ sudo apt update
```

```
$ sudo apt install glusterfs-server
```

Start the GlusterFS Daemon

Start the GlusterFS daemon:

```
$ sudo systemctl start glusterd
```

```
$ sudo systemctl enable glusterd
```

Probe the GlusterFS Peers

Before you can create a volume with GlusterFS, you must probe each node from a peer node.

1. On the primary node, probe all of the other cluster nodes:

```
$ sudo gluster peer probe mcs2
```

```
$ sudo gluster peer probe mcs3
```

2. On one of the replica nodes, probe the primary node to confirm that it is connected:

```
$ sudo gluster peer probe mcs1

peer probe: Host mcs1 port 24007 already in peer list
```

3. On the primary node, check the peer status:

```
$ sudo gluster peer status
```

Number of Peers: 2

```
Hostname: mcs2
Uuid: 3c8a5c79-22de-45df-9034-8ae624b7b23e
State: Peer in Cluster (Connected)

Hostname: mcs3
Uuid: 862af7b2-bb5e-4b1c-8311-630fa32ed451
State: Peer in Cluster (Connected)
```

Configure and Mount GlusterFS Volumes

Create the GlusterFS volumes for MariaDB Enterprise ColumnStore. Each volume must have the same number of replicas as the number of Enterprise ColumnStore nodes.

1. On each Enterprise ColumnStore node, create the directory for each brick in the /brick directory:

```
$ sudo mkdir -p /brick/storagemanager
```

2. On the primary node, create the GlusterFS volumes:

```
$ sudo gluster volume create storagemanager \
      replica 3 \
      mcs1:/brick/storagemanager \
      mcs2:/brick/storagemanager \
      mcs3:/brick/storagemanager \
      force
```

3. On the primary node, start the volume:

```
$ sudo gluster volume start storagemanager
```

4. On each Enterprise ColumnStore node, create mount points for the volumes:

```
$ sudo mkdir -p /var/lib/columnstore/storagemanager
```

5. On each Enterprise ColumnStore node, add the mount points to /etc/fstab:

```
127.0.0.1:storagemanager /var/lib/columnstore/storagemanager glusterfs defaults,_netdev 0 0
```

6. On each Enterprise ColumnStore node, mount the volumes:

```
$ sudo mount -a
```

Configure Network File System (NFS)

NFS is a distributed file system. NFS is available in most Linux distributions. If NFS is used for an Enterprise ColumnStore deployment, the storage must be mounted with the sync option to ensure that each node flushes its changes immediately.

For on-premises deployments:

- NFS is the recommended option for the Storage Manager directory.
- Any S3-compatible storage is the recommended option for data.

Consult the documentation for your NFS implementation for details on how to configure NFS.

Next Step

Navigation in the procedure “Deploy ColumnStore Shared Local Storage Topology”.

This page was step 2 of 9.

Next: Step 3: Install MariaDB Enterprise Server.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 3: Install MariaDB Enterprise Server

Overview

This page details step 3 of the 9-step procedure "Deploy ColumnStore Shared Local Storage Topology".

This step installs MariaDB Enterprise Server, MariaDB Enterprise ColumnStore 23.10, CMAPI, and dependencies.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Retrieve Download Token

MariaDB Corporation provides package repositories for CentOS / RHEL (YUM) and Debian / Ubuntu (APT). A download token is required to access the MariaDB Enterprise Repository.

Customer Download Tokens are customer-specific and are available through the MariaDB Customer Portal.

To retrieve the token for your account:

1. Navigate to https://customers.mariadb.com/downloads/token/
2. Log in.
3. Copy the Customer Download Token.

Substitute your token for `CUSTOMER_DOWNLOAD_TOKEN` when configuring the package repositories.

Set Up Repository

1. On each Enterprise ColumnStore node, install the prerequisites for downloading the software from the Web. Install on CentOS / RHEL (YUM):

```
$ sudo yum install curl
```

Install on Debian / Ubuntu (APT):

```
$ sudo apt install curl apt-transport-https
```

2. On each Enterprise ColumnStore node, configure package repositories and specify Enterprise Server:

```
$ curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
```

```
$ echo "${checksum}  mariadb_es_repo_setup" \
       | sha256sum -c -
```

```
$ chmod +x mariadb_es_repo_setup
```

```
$ sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
      --skip-maxscale \
      --skip-tools \
      --mariadb-server-version="11.4"
```

Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.

Install Enterprise Server and Enterprise ColumnStore

1. On each Enterprise ColumnStore node, install additional dependencies:

Install on CentOS and RHEL (YUM):

```
$ sudo yum install jemalloc jq curl
```

Install on Debian 9 and Ubuntu 18.04 (APT)

```
$ sudo apt install libjemalloc1 jq curl
```

Install on Debian 10 and Ubuntu 20.04 (APT):

```
$ sudo apt install libjemalloc2 jq curl
```

2. On each Enterprise ColumnStore node, install MariaDB Enterprise Server and MariaDB Enterprise ColumnStore:

Install on CentOS / RHEL (YUM):

```
$ sudo yum install MariaDB-server \
   MariaDB-backup \
   MariaDB-shared \
   MariaDB-client \
   MariaDB-columnstore-engine \
   MariaDB-columnstore-cmapi
```

Install on Debian / Ubuntu (APT):

```
$ sudo apt install mariadb-server \
   mariadb-backup \
   libmariadb3 \
   mariadb-client \
   mariadb-plugin-columnstore \
   mariadb-columnstore-cmapi
```

Next Step

Navigation in the procedure “Deploy ColumnStore Shared Local Storage Topology”.

This page was step 3 of 9.

Next: Step 4: Start and Configure MariaDB Enterprise Server.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 4: Start and Configure MariaDB Enterprise Server

Overview

This page details step 4 of the 9-step procedure “Deploy ColumnStore Shared Local Storage Topology”.

This step starts and configures MariaDB Enterprise Server, and MariaDB Enterprise ColumnStore 23.10.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Stop the Enterprise ColumnStore Services

The installation process might have started some of the ColumnStore services. The services should be stopped prior to making configuration changes.

1. On each Enterprise ColumnStore node, stop the MariaDB Enterprise Server service:

```
$ sudo systemctl stop mariadb
```

2. On each Enterprise ColumnStore node, stop the MariaDB Enterprise ColumnStore service:

```
$ sudo systemctl stop mariadb-columnstore
```

3. On each Enterprise ColumnStore node, stop the CMAPI service:

```
$ sudo systemctl stop mariadb-columnstore-cmapi
```

Configure Enterprise ColumnStore

On each Enterprise ColumnStore node, configure Enterprise Server.

Connector	MariaDB Connector/R2DBC
character_set_server	Set this system variable to utf8
collation_server	Set this system variable to utf8_general_ci
loose-columnstore_use_import_for_batchinsert	Set this system variable to ALWAYS to always use cpimport for LOAD DATA INFILE and INSERT…SELECT statements.
gtid_strict_mode	Set this system variable to ON.
log_bin	Set this option to the file you want to use for the Binary Log. Setting this option enables binary logging.
log_bin_index	Set this option to the file you want to use to track binlog filenames.
log_slave_updates	Set this system variable to ON.
relay_log	Set this option to the file you want to use for the Relay Logs. Setting this option enables relay logging.
relay_log_index	Set this option to the file you want to use to index Relay Log filenames.
server_id	Sets the numeric Server ID for this MariaDB Enterprise Server. The value set on this option must be unique to each node.

Mandatory system variables and options for ColumnStore Object Storage include:

Example Configuration

```
[mariadb]
bind_address                            = 0.0.0.0
log_error                               = mariadbd.err
character_set_server                    = utf8
collation_server                        = utf8_general_ci
log_bin                                 = mariadb-bin
log_bin_index                           = mariadb-bin.index
relay_log                               = mariadb-relay
relay_log_index                         = mariadb-relay.index
log_slave_updates                       = ON
gtid_strict_mode                        = ON

# This must be unique on each Enterprise ColumnStore node
server_id                               = 1
```

Start the Enterprise ColumnStore Services

1. On each Enterprise ColumnStore node, start and enable the MariaDB Enterprise Server service, so that it starts automatically upon reboot:

```
$ sudo systemctl start mariadb
```

```
$ sudo systemctl enable mariadb
```

2. On each Enterprise ColumnStore node, stop the MariaDB Enterprise ColumnStore service:

```
$ sudo systemctl stop mariadb-columnstore
```

After the CMAPI service is installed in the next step, CMAPI will start the Enterprise ColumnStore service as-needed on each node. CMAPI disables the Enterprise ColumnStore service to prevent systemd from automatically starting Enterprise ColumnStore upon reboot.

3. On each Enterprise ColumnStore node, start and enable the CMAPI service, so that it starts automatically upon reboot:

```
$ sudo systemctl start mariadb-columnstore-cmapi
```

```
$ sudo systemctl enable mariadb-columnstore-cmapi
```

For additional information, see “Start and Stop Services”.

Create User Accounts

The ColumnStore Object Storage topology requires several user accounts. Each user account should be created on the primary server, so that it is replicated to the replica servers.

Create the Utility User

Enterprise ColumnStore requires a mandatory utility user account to perform cross-engine joins and similar operations.

1. On the primary server, create the user account with the CREATE USER statement:

```
CREATE USER 'util_user'@'127.0.0.1'
IDENTIFIED BY 'util_user_passwd';
```

2. On the primary server, grant the user account SELECT privileges on all databases with the GRANT statement:

```
GRANT SELECT, PROCESS ON *.*
TO 'util_user'@'127.0.0.1';
```

3. On each Enterprise ColumnStore node, configure the ColumnStore utility user:

```
$ sudo mcsSetConfig CrossEngineSupport Host 127.0.0.1
```

```
$ sudo mcsSetConfig CrossEngineSupport Port 3306
```

```
$ sudo mcsSetConfig CrossEngineSupport User util_user
```

4. On each Enterprise ColumnStore node, set the password:

```
$ sudo mcsSetConfig CrossEngineSupport Password util_user_passwd
```

For details about how to encrypt the password, see “Credentials Management for MariaDB Enterprise ColumnStore”.

Passwords should meet your organization’s password policies. If your MariaDB Enterprise Server instance has a password validation plugin installed, then the password should also meet the configured requirements.

Create the Replication User

ColumnStore Object Storage uses MariaDB Replication to replicate writes between the primary and replica servers. As MaxScale can promote a replica server to become a new primary in the event of node failure, all nodes must have a replication user.

The action is performed **on the primary server**.

Create the replication user and grant it the required privileges:

1. Use the CREATE USER statement to create replication user.

```
CREATE USER 'repl'@'192.0.2.%' IDENTIFIED BY 'repl_passwd';
```

Replace the referenced IP address with the relevant address for your environment.

Ensure that the user account can connect to the primary server from each replica.

2. Grant the user account the required privileges with the GRANT statement.

```
GRANT REPLICA MONITOR,
   REPLICATION REPLICA,
   REPLICATION REPLICA ADMIN,
   REPLICATION MASTER ADMIN
ON *.* TO 'repl'@'192.0.2.%';
```

Create MaxScale User

ColumnStore Object Storage 23.10 uses MariaDB MaxScale 22.08 to load balance between the nodes.

This action is performed on the primary server.

1. Use the CREATE USER statement to create the MaxScale user:

```
CREATE USER 'mxs'@'192.0.2.%'
IDENTIFIED BY 'mxs_passwd';
```

Replace the referenced IP address with the relevant address for your environment.

Ensure that the user account can connect from the IP address of the MaxScale instance.

2. Use the GRANT statement to grant the privileges required by the router:

```
GRANT SHOW DATABASES ON *.* TO 'mxs'@'192.0.2.%';

GRANT SELECT ON mysql.columns_priv TO 'mxs'@'192.0.2.%';

GRANT SELECT ON mysql.db TO 'mxs'@'192.0.2.%';

GRANT SELECT ON mysql.procs_priv TO 'mxs'@'192.0.2.%';

GRANT SELECT ON mysql.proxies_priv TO 'mxs'@'192.0.2.%';

GRANT SELECT ON mysql.roles_mapping TO 'mxs'@'192.0.2.%';

GRANT SELECT ON mysql.tables_priv TO 'mxs'@'192.0.2.%';

GRANT SELECT ON mysql.user TO 'mxs'@'192.0.2.%';
```

3. Use the GRANT statement to grant privileges required by the MariaDB Monitor.

```
GRANT BINLOG ADMIN,
   READ_ONLY ADMIN,
   RELOAD,
   REPLICA MONITOR,
   REPLICATION MASTER ADMIN,
   REPLICATION REPLICA ADMIN,
   REPLICATION REPLICA,
   SHOW DATABASES,
   SELECT
ON *.* TO 'mxs'@'192.0.2.%';
```

Configure MariaDB Replication

On each replica server, configure MariaDB Replication:

1. Use the CHANGE MASTER TO statement to configure the connection to the primary server:

```
CHANGE MASTER TO
   MASTER_HOST='192.0.2.1',
   MASTER_USER='repl',
   MASTER_PASSWORD='repl_passwd',
   MASTER_USE_GTID=slave_pos;
```

2. Start replication using the START REPLICA statement:

```
START REPLICA;
```

3. Confirm that replication is working using the SHOW REPLICA STATUS statement:

```
SHOW REPLICA STATUS;
```

Ensure that the replica server cannot accept local writes by setting the read_only system variable to ON using the SET GLOBAL statement:

```
SET GLOBAL read_only=ON;
```

Initiate the Primary Server with CMAPI

Initiate the primary server using CMAPI.

1. Create an API key for the cluster.
   This API key should be stored securely and kept confidential, because it can be used to add cluster nodes to the multi-node Enterprise ColumnStore deployment.

For example, to create a random 256-bit API key using openssl rand:

```
$ openssl rand -hex 32

93816fa66cc2d8c224e62275bd4f248234dd4947b68d4af2b29671dd7d5532dd
```

This document will use the following API key in further examples, but users should create their own:

2. Use CMAPI to add the primary server to the cluster and set the API key.
   The new API key needs to be provided as part of the X-API-key HTML header.

For example, if the primary server's host name is mcs1 and its IP address is 192.0.2.1, use the following node command:

```
$ curl -k -s -X PUT https://mcs1:8640/cmapi/0.4.0/cluster/node \
   --header 'Content-Type:application/json' \
   --header 'x-api-key:93816fa66cc2d8c224e62275bd4f248234dd4947b68d4af2b29671dd7d5532dd' \
   --data '{"timeout":120, "node": "192.0.2.1"}' \
   | jq .
```

```
{
  "timestamp": "2020-10-28 00:39:14.672142",
  "node_id": "192.0.2.1"
}
```

3. Use CMAPI to check the status of the cluster node:

```
$ curl -k -s https://mcs1:8640/cmapi/0.4.0/cluster/status \
   --header 'Content-Type:application/json' \
   --header 'x-api-key:93816fa66cc2d8c224e62275bd4f248234dd4947b68d4af2b29671dd7d5532dd' \
   | jq .
```

```
{
  "timestamp": "2020-12-15 00:40:34.353574",
  "192.0.2.1": {
    "timestamp": "2020-12-15 00:40:34.362374",
    "uptime": 11467,
    "dbrm_mode": "master",
    "cluster_mode": "readwrite",
    "dbroots": [
      "1"
    ],
    "module_id": 1,
    "services": [
      {
        "name": "workernode",
        "pid": 19202
      },
      {
        "name": "controllernode",
        "pid": 19232
      },
      {
        "name": "PrimProc",
        "pid": 19254
      },
      {
        "name": "ExeMgr",
        "pid": 19292
      },
      {
        "name": "WriteEngine",
        "pid": 19316
      },
      {
        "name": "DMLProc",
        "pid": 19332
      },
      {
        "name": "DDLProc",
        "pid": 19366
      }
    ]
  }
```

Add Replica Servers with CMAPI

Add the replica servers with CMAPI:

1. For each replica server, use CMAPI to add the replica server to the cluster.
   The previously set API key needs to be provided as part of the X-API-key HTML header.

For example, if the primary server's host name is mcs1 and the replica server's IP address is 192.0.2.2, use the following node command:

```
$ curl -k -s -X PUT https://mcs1:8640/cmapi/0.4.0/cluster/node \
   --header 'Content-Type:application/json' \
   --header 'x-api-key:93816fa66cc2d8c224e62275bd4f248234dd4947b68d4af2b29671dd7d5532dd' \
   --data '{"timeout":120, "node": "192.0.2.2"}' \
   | jq .
```

```
{
  "timestamp": "2020-10-28 00:42:42.796050",
  "node_id": "192.0.2.2"
}
```

2. After all replica servers have been added, use CMAPI to confirm that all cluster nodes have been successfully added:

```
$ curl -k -s https://mcs1:8640/cmapi/0.4.0/cluster/status \
   --header 'Content-Type:application/json' \
   --header 'x-api-key:93816fa66cc2d8c224e62275bd4f248234dd4947b68d4af2b29671dd7d5532dd' \
   | jq .
```

```
{
  "timestamp": "2020-12-15 00:40:34.353574",
  "192.0.2.1": {
    "timestamp": "2020-12-15 00:40:34.362374",
    "uptime": 11467,
    "dbrm_mode": "master",
    "cluster_mode": "readwrite",
    "dbroots": [
      "1"
    ],
    "module_id": 1,
    "services": [
      {
        "name": "workernode",
        "pid": 19202
      },
      {
        "name": "controllernode",
        "pid": 19232
      },
      {
        "name": "PrimProc",
        "pid": 19254
      },
      {
        "name": "ExeMgr",
        "pid": 19292
      },
      {
        "name": "WriteEngine",
        "pid": 19316
      },
      {
        "name": "DMLProc",
        "pid": 19332
      },
      {
        "name": "DDLProc",
        "pid": 19366
      }
    ]
  },
  "192.0.2.2": {
    "timestamp": "2020-12-15 00:40:34.428554",
    "uptime": 11437,
    "dbrm_mode": "slave",
    "cluster_mode": "readonly",
    "dbroots": [
      "2"
    ],
    "module_id": 2,
    "services": [
      {
        "name": "workernode",
        "pid": 17789
      },
      {
        "name": "PrimProc",
        "pid": 17813
      },
      {
        "name": "ExeMgr",
        "pid": 17854
      },
      {
        "name": "WriteEngine",
        "pid": 17877
      }
```

```
    ]
  },
  "192.0.2.3": {
    "timestamp": "2020-12-15 00:40:34.428554",
    "uptime": 11437,
    "dbrm_mode": "slave",
    "cluster_mode": "readonly",
    "dbroots": [
      "2"
    ],
    "module_id": 2,
    "services": [
      {
        "name": "workernode",
        "pid": 17789
      },
      {
        "name": "PrimProc",
        "pid": 17813
      },
      {
        "name": "ExeMgr",
        "pid": 17854
      },
      {
        "name": "WriteEngine",
        "pid": 17877
      }
    ]
  },
  "num_nodes": 3
}
```

Configure Linux Security Modules (LSM)

The specific steps to configure the security module depend on the operating system.

Configure SELinux (CentOS, RHEL)

Configure SELinux for Enterprise ColumnStore:

1. To configure SELinux, you have to install the packages required for audit2allow.
   On CentOS 7 and RHEL 7, install the following:

```
$ sudo yum install policycoreutils policycoreutils-python
```

On RHEL 8, install the following:

```
$ sudo yum install policycoreutils python3-policycoreutils policycoreutils-python-utils
```

2. Allow the system to run under load for a while to generate SELinux audit events.
3. After the system has taken some load, generate an SELinux policy from the audit events using audit2allow:

```
$ sudo grep mysqld /var/log/audit/audit.log | audit2allow -M mariadb_local
```

If no audit events were found, this will print the following:

```
$ sudo grep mysqld /var/log/audit/audit.log | audit2allow -M mariadb_local

Nothing to do
```

4. If audit events were found, the new SELinux policy can be loaded using semodule:

```
$ sudo semodule -i mariadb_local.pp
```

5. Set SELinux to enforcing mode:

```
$ sudo setenforce enforcing
```

6. Set SELinux to enforcing mode by setting SELINUX=enforcing in /etc/selinux/config.

For example, the file will usually look like this after the change:

```
# This file controls the state of SELinux on the system.
# SELINUX= can take one of these three values:
#     enforcing - SELinux security policy is enforced.
#     permissive - SELinux prints warnings instead of enforcing.
#     disabled - No SELinux policy is loaded.
SELINUX=enforcing
# SELINUXTYPE= can take one of three values:
#     targeted - Targeted processes are protected,
#     minimum - Modification of targeted policy. Only selected processes are protected.
#     mls - Multi Level Security protection.
SELINUXTYPE=targeted
```

7. Confirm that SELinux is in enforcing mode:

```
$ sudo getenforce
```

```
Enforcing
```

Configure AppArmor (Ubuntu)

For information on how to create a profile, see How to create an AppArmor Profile on Ubuntu.com.

Configure Firewalls

The specific steps to configure the firewall service depend on the platform.

Configure firewalld (CentOS, RHEL)

Configure firewalld for Enterprise Cluster on CentOS and RHEL:

1. Check if the firewalld service is running:

```
$ sudo systemctl status firewalld
```

2. If the firewalld service was stopped to perform the installation, start it now:

For example, if your cluster nodes are in the 192.0.2.0/24 subnet:

```
$ sudo systemctl start firewalld
```

3. Open up the relevant ports using firewall-cmd:

```
$ sudo firewall-cmd --permanent --add-rich-rule='
   rule family="ipv4"
   source address="192.0.2.0/24"
   destination address="192.0.2.0/24"
   port port="3306" protocol="tcp"
   accept'
```

```
$ sudo firewall-cmd --permanent --add-rich-rule='
   rule family="ipv4"
   source address="192.0.2.0/24"
   destination address="192.0.2.0/24"
   port port="8600-8630" protocol="tcp"
   accept'
```

```
$ sudo firewall-cmd --permanent --add-rich-rule='
   rule family="ipv4"
   source address="192.0.2.0/24"
   destination address="192.0.2.0/24"
   port port="8640" protocol="tcp"
   accept'
```

```
$ sudo firewall-cmd --permanent --add-rich-rule='
   rule family="ipv4"
   source address="192.0.2.0/24"
   destination address="192.0.2.0/24"
   port port="8700" protocol="tcp"
   accept'
```

```
$ sudo firewall-cmd --permanent --add-rich-rule='
   rule family="ipv4"
   source address="192.0.2.0/24"
   destination address="192.0.2.0/24"
   port port="8800" protocol="tcp"
   accept'
```

4. Reload the runtime configuration:

```
$ sudo firewall-cmd --reload
```

Configure UFW (Ubuntu)

Configure UFW for Enterprise ColumnStore on Ubuntu:

1. Check if the UFW service is running:

```
$ sudo ufw status verbose
```

2. If the UFW service was stopped to perform the installation, start it now:

```
$ sudo ufw enable
```

3. Open up the relevant ports using ufw.

For example, if your cluster nodes are in the 192.0.2.0/24 subnet in the range 192.0.2.1 - 192.0.2.3:

```
$ sudo ufw allow from 192.0.2.0/24 to 192.0.2.3 port 3306 proto tcp

$ sudo ufw allow from 192.0.2.0/24 to 192.0.2.3 port 8600:8630 proto tcp

$ sudo ufw allow from 192.0.2.0/24 to 192.0.2.3 port 8640 proto tcp

$ sudo ufw allow from 192.0.2.0/24 to 192.0.2.3 port 8700 proto tcp

$ sudo ufw allow from 192.0.2.0/24 to 192.0.2.3 port 8800 proto tcp
```

4. Reload the runtime configuration:

```
$ sudo ufw reload
```

Next Step

Navigation in the procedure “Deploy ColumnStore Shared Local Storage Topology”.

This page was step 4 of 9.

Next: Step 5: Test MariaDB Enterprise Server.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 5: Test MariaDB Enterprise Server

Overview

This page details step 5 of the 9-step procedure “Deploy ColumnStore Shared Local Storage Topology”.

This step tests MariaDB Enterprise Server and MariaDB Enterprise ColumnStore 23.10.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Test Enterprise Server Service

Use Systemd to test whether the MariaDB Enterprise Server service is running.

This action is performed **on each Enterprise ColumnStore node**.

Check if the MariaDB Enterprise Server service is running by executing the following:

```
$ systemctl status mariadb
```

If the service is not running on any node, start the service by executing the following on that node:

```
$ sudo systemctl start mariadb
```

Test Local Client Connections

Use MariaDB Client to test the local connection to the Enterprise Server node.

This action is performed **on each Enterprise ColumnStore node**:

```
$ sudo mariadb
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 38
Server version: 11.4.5-3-MariaDB-Enterprise MariaDB Enterprise Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]>
```

The `sudo` command is used here to connect to the Enterprise Server node using the root@localhost user account, which authenticates using the unix_socket authentication plugin. Other user accounts can be used by specifying the –user and –password command-line options.

Test ColumnStore Storage Engine Plugin

Query the information_schema.PLUGINS table to confirm that the ColumnStore storage engine is loaded.

This action is performed on each Enterprise ColumnStore node.

Execute the following query:

```
SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM information_schema.PLUGINS
WHERE PLUGIN_LIBRARY LIKE 'ha_columnstore%';

+--------------------+---------------+
| PLUGIN_NAME        | PLUGIN_STATUS |
+--------------------+---------------+
| Columnstore        | ACTIVE        |
| COLUMNSTORE_COLUMNS | ACTIVE        |
| COLUMNSTORE_TABLES  | ACTIVE        |
| COLUMNSTORE_FILES   | ACTIVE        |
| COLUMNSTORE_EXTENTS | ACTIVE        |
+--------------------+---------------+
```

The `PLUGIN_STATUS` column for each ColumnStore-related plugin should contain ACTIVE.

Test CMAPI Service

Use Systemd to test whether the CMAPI service is running.

This action is performed on each Enterprise ColumnStore node.

Check if the CMAPI service is running by executing the following:

```
$ systemctl status mariadb-columnstore-cmapi
```

If the service is not running on any node, start the service by executing the following on that node:

```
$ sudo systemctl start mariadb-columnstore-cmapi
```

Test ColumnStore Status

Use CMAPI to request the ColumnStore status. The API key needs to be provided as part of the `X-API-key` HTML header.

This action is performed with the CMAPI service on the primary server.

Check the ColumnStore status using curl by executing the following:

```
$ curl -k -s https://mcs1:8640/cmapi/0.4.0/cluster/status \
   --header 'Content-Type:application/json' \
   --header 'x-api-key:93816fa66cc2d8c224e62275bd4f248234dd4947b68d4af2b29671dd7d5532dd' \
   | jq .
```

```

    ]
  },
  "num_nodes": 3
}
```

Test DDL

Use MariaDB Client to test DDL.

1. On the primary server, use the MariaDB Client to connect to the node:

```
$ sudo mariadb
```

2. Create a test database and ColumnStore table:

```
CREATE DATABASE IF NOT EXISTS test;

CREATE TABLE IF NOT EXISTS test.contacts (
   first_name VARCHAR(50),
   last_name VARCHAR(50),
   email VARCHAR(100)
) ENGINE = ColumnStore;
```

3. On each replica server, use the MariaDB Client to connect to the node:

```
$ sudo mariadb
```

4. Confirm that the database and table exist:

```
SHOW CREATE TABLE test.contacts\G;
```

If the database or table do not exist on any node, then check the replication configuration.

Test DML

Use MariaDB Client to test DML.

1. On the primary server, use the MariaDB Client to connect to the node:

```
$ sudo mariadb
```

2. Insert sample data into the table created in the DDL test:

```
INSERT INTO test.contacts (first_name, last_name, email)
   VALUES
   ("Kai", "Devi", "kai.devi@example.com"),
   ("Lee", "Wang", "lee.wang@example.com");
```

3. On each replica server, use the MariaDB Client to connect to the node:

```
$ sudo mariadb
```

4. Execute a SELECT query to retrieve the data:

```
SELECT * FROM test.contacts;

+------------+-----------+----------------------+
| first_name | last_name | email                |
+------------+-----------+----------------------+
| Kai        | Devi      | kai.devi@example.com |
| Lee        | Wang      | lee.wang@example.com |
+------------+-----------+----------------------+
```

If the data is not returned on any node, check the ColumnStore status and the storage configuration.

Next Step

Navigation in the procedure “Deploy ColumnStore Shared Local Storage Topology”.

This page was step 5 of 9.

Next: Step 6: Install MariaDB MaxScale.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 6: Install MariaDB MaxScale

Overview

This page details step 6 of the 9-step procedure “Deploy ColumnStore Shared Local Storage Topology”.

This step installs MariaDB MaxScale 22.08.

ColumnStore Object Storage requires 1 or more MaxScale nodes.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Retrieve Customer Download Token

MariaDB Corporation provides package repositories for `CentOS / RHEL (YUM) and Debian / Ubuntu (APT)`. A download token is required to access the MariaDB Enterprise Repository.

Customer Download Tokens are customer-specific and are available through the MariaDB Customer Portal.

To retrieve the token for your account:

1. Navigate to
2. Log in.
3. Copy the Customer Download Token.

Substitute your token for `CUSTOMER_DOWNLOAD_TOKEN` when configuring the package repositories.

Set Up Repository

1. On the MaxScale node, install the prerequisites for downloading the software from the Web.
   Install on CentOS / RHEL (YUM):

```
$ sudo yum install curl
```

Install on Debian / Ubuntu (APT):

```
$ sudo apt install curl apt-transport-https
```

2. On the MaxScale node, configure package repositories and specify MariaDB MaxScale 22.08:

```
$ curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup

$ echo "${checksum}  mariadb_es_repo_setup" \
       | sha256sum -c -

$ chmod +x mariadb_es_repo_setup

$ sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
      --skip-server \
      --skip-tools \
      --mariadb-maxscale-version="22.08"
```

Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.

Install MaxScale

On the MaxScale node, install MariaDB MaxScale.

Install on CentOS / RHEL (YUM):

```
$ sudo yum install maxscale
```

Install on Debian / Ubuntu (APT):

```
$ sudo apt install maxscale
```

Next Step

Navigation in the procedure “Deploy ColumnStore Shared Local Storage Topology”.

This page was step 6 of 9.

Next: Step 7: Start and Configure MariaDB MaxScale.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 7: Start and Configure MariaDB MaxScale

Overview

This page details step 7 of the 9-step procedure “Deploy ColumnStore Shared Local Storage Topology”.

This step starts and configures MariaDB MaxScale 22.08.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Replace the Default Configuration File

MariaDB MaxScale installations include a configuration file with some example objects. This configuration file should be replaced.

On the MaxScale node, replace the default `/etc/maxscale.cnf` with the following configuration:

```
[maxscale]
threads          = auto
admin_host       = 0.0.0.0
admin_secure_gui = false
```

For additional information, see “Global Parameters”.

Restart MaxScale

On the MaxScale node, restart the MaxScale service to ensure that MaxScale picks up the new configuration:

```
$ sudo systemctl restart maxscale
```

For additional information, see “Start and Stop Services”.

Configure Server Objects

On the MaxScale node, use maxctrl create to create a server object for each Enterprise ColumnStore node:

```
$ maxctrl create server mcs1 192.0.2.101
```

```
$ maxctrl create server mcs2 192.0.2.102
```

```
$ maxctrl create server mcs3 192.0.2.103
```

Configure MariaDB Monitor

MaxScale uses monitors to retrieve additional information from the servers. This information is used by other services in filtering and routing connections based on the current state of the node. For MariaDB Enterprise ColumnStore, use the MariaDB Monitor (mariadbmon).

On the MaxScale node, use maxctrl create monitor to create a MariaDB Monitor:

```
$ maxctrl create monitor columnstore_monitor mariadbmon \
     user=mxs \
     password='MAXSCALE_USER_PASSWORD' \
     replication_user=repl \
     replication_password='REPLICATION_USER_PASSWORD' \
     --servers mcs1 mcs2 mcs3
```

In this example:

- `columnstore_monitor` is an arbitrary name that is used to identify the new monitor.
- `mariadbmon` is the name of the module that implements the MariaDB Monitor.
- `user=MAXSCALE_USER` sets the user parameter to the database user account that MaxScale uses to monitor the ColumnStore nodes.
- `password='MAXSCALE_USER_PASSWORD'` sets the password parameter to the password used by the database user account that MaxScale uses to monitor the ColumnStore nodes.

- `replication_user=REPLICATION_USER` sets the replication_user parameter to the database user account that MaxScale uses to setup replication.
- `replication_password='REPLICATION_USER_PASSWORD'` sets the replication_password parameter to the password used by the database user account that MaxScale uses to setup replication.
- `--servers` sets the servers parameter to the set of nodes that MaxScale should monitor. All non-option arguments after `--servers` are interpreted as server names.
- Other Module Parameters supported by mariadbmon in MaxScale 22.08 can also be specified.

Choose a MaxScale Router

Routers control how MaxScale balances the load between Enterprise ColumnStore nodes. Each router uses a different approach to routing queries. Consider the specific use case of your application and database load and select the router that best suits your needs.

Router	Configuration Procedure	Description
Read Connection (readconnroute)	Configure Read Connection Router	
Read/Write Split (readwritesplit)	Configure Read/Write Split	

Configure Read Connection Router

Use MaxScale Read Connection Router (readconnroute) to route connections to replica servers for a read-only pool.

On the MaxScale node, use maxctrl create service to create a router:

```
$ maxctrl create service connection_router_service readconnroute \
     user=mxs \
     password='MAXSCALE_USER_PASSWORD' \
     router_options=slave \
     --servers mcs1 mcs2 mcs3
```

In this example:

- `connection_router_service` is an arbitrary name that is used to identify the new service.
- readconnroute is the name of the module that implements the Read Connection Router.
- `user=MAXSCALE_USER` sets the user parameter to the database user account that MaxScale uses to connect to the ColumnStore nodes.
- `password=MAXSCALE_USER_PASSWORD` sets the password parameter to the password used by the database user account that MaxScale uses to connect to the ColumnStore nodes.
- `router_options=slave` sets the `router_options` parameter to slave, so that MaxScale only routes connections to the replica nodes.
- `--servers` sets the servers parameter to the set of nodes to which MaxScale should route connections. All non-option arguments after `--servers` are interpreted as server names.
- Other Module Parameters supported by `readconnroute` in MaxScale 22.08 can also be specified.

Configure Listener for the Read Connection Router

These instructions reference TCP port 3308. You can use a different TCP port. The TCP port used must not be bound by any other listener.

On the MaxScale node, use the maxctrl create listener command to configure MaxScale to use a listener for the Read Connection Router (readconnroute):

```
$ maxctrl create listener connection_router_service connection_router_listener 3308 \
     protocol=MariaDBClient
```

In this example:

- `connection_router_service` is the name of the `readconnroute` service that was previously created.
- `connection_router_listener` is an arbitrary name that is used to identify the new listener.
- 3308 is the TCP port.
- `protocol=MariaDBClient` sets the protocol parameter.
- Other Module Parameters supported by listeners in MaxScale 22.08 can also be specified.

Configure Read/Write Split Router for Queries

MaxScale Read/Write Split Router (readwritesplit) performs query-based load balancing. The router routes write queries to the primary and read queries to the replicas.

On the MaxScale node, use the maxctrl create service command to configure MaxScale to use the Read/Write Split Router (readwritesplit):

```
$ maxctrl create service query_router_service readwritesplit  \
     user=mxs \
     password='MAXSCALE_USER_PASSWORD' \
     --servers mcs1 mcs2 mcs3
```

In this example:

- `query_router_service` is an arbitrary name that is used to identify the new service.
- `readwritesplit` is the name of the module that implements the Read/Write Split Router.
- `user=MAXSCALE_USER` sets the user parameter to the database user account that MaxScale uses to connect to the ColumnStore nodes.
- `password=MAXSCALE_USER_PASSWORD` sets the password parameter to the password used by the database user account that MaxScale uses to connect to the ColumnStore nodes.
- `--servers` sets the servers parameter to the set of nodes to which MaxScale should route queries. All non-option arguments after `--servers` are interpreted as server names.
- Other Module Parameters supported by `readwritesplit` in MaxScale 22.08 can also be specified.

Configure a Listener for the Read/Write Split Router

These instructions reference TCP port 3307. You can use a different TCP port. The TCP port used must not be bound by any other listener.

On the MaxScale node, use the maxctrl create listener command to configure MaxScale to use a listener for the Read/Write Split Router (readwritesplit):

```
$ maxctrl create listener query_router_service query_router_listener 3307 \
     protocol=MariaDBClient
```

In this example:

- `query_router_service` is the name of the readwritesplit service that was previously created.
- `query_router_listener` is an arbitrary name that is used to identify the new listener.
- 3307 is the TCP port.
- `protocol=MariaDBClient` sets the protocol parameter.
- Other Module Parameters supported by listeners in MaxScale 22.08 can also be specified.

Start Services

To start the services and monitors, on the MaxScale node use maxctrl start services:

```
$ maxctrl start services
```

Next Step

Navigation in the procedure “Deploy ColumnStore Shared Local Storage Topology”.

This page was step 7 of 9.

Next: Next: Step 8: Test MariaDB MaxScale.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 8: Test MariaDB MaxScale

Overview

This page details step 8 of the 9-step procedure “Deploy ColumnStore Shared Local Storage Topology”.

This step tests MariaDB MaxScale 22.08.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Check Global Configuration

Use maxctrl show maxscale command to view the global MaxScale configuration.

This action is performed **on the MaxScale node**:

```
$ maxctrl show maxscale
```

```

└───────────────┴─────────────────────────────────────────────────────────┘
```

Output should align to the global MaxScale configuration in the new configuration file you created.

Check Server Configuration

Use the maxctrl list servers and maxctrl show server commands to view the configured server objects.

This action is performed **on the MaxScale node**:

1. Obtain the full list of servers objects:

```
$ maxctrl list servers
```

```
┌────────┬───────────────┬──────┬─────────────┬─────────────────┬──────────┐
| Server | Address       | Port | Connections | State           | GTID     |
├────────┼───────────────┼──────┼─────────────┼─────────────────┼──────────┤
| mcs1   | 192.0.2.1     | 3306 | 1           | Master, Running | 0-1-25 |
├────────┼───────────────┼──────┼─────────────┼─────────────────┼──────────┤
| mcs2   | 192.0.2.2     | 3306 | 1           | Slave, Running  | 0-1-25 |
├────────┼───────────────┼──────┼─────────────┼─────────────────┼──────────┤
| mcs3   | 192.0.2.3     | 3306 | 1           | Slave, Running  | 0-1-25 |
└────────┴───────────────┴──────┴─────────────┴─────────────────┴──────────┘
```

For each server object, view the configuration:

```
$ maxctrl show server mcs1
```

```
┌──────────────────┬──────────────────────────────────────────────────┐

└─────────────────────┴────────────────────────────────────────────────────┘
```

Output should align to the Server Object configuration you performed.

Check Monitor Configuration

Use the maxctrl list monitors and maxctrl show monitor commands to view the configured monitors.

This action is performed on the MaxScale node:

1. Obtain the full list of monitors:

```
$ maxctrl list monitors
```

```
┌──────────────────────┬─────────┬──────────────────┐
│ Monitor              │ State   │ Servers          │
├──────────────────────┼─────────┼──────────────────┤
│ columnstore_monitor │ Running │ mcs1, mcs2, mcs3 │
└──────────────────────┴─────────┴──────────────────┘
```

2. For each monitor, view the monitor configuration:

```
$ maxctrl show monitor columnstore_monitor
```

```
┌──────────────────────┬──────────────────────────────────────────┐
│ Monitor              │ columnstore_monitor                      │

└──────────────────────┴─────────────────────────────────────────────────────────────────────┘
```

Output should align to the Read Connection Router (readconnroute) or Read/Write Split Router (readwritesplit) configuration you performed.

Test Application User

Applications should use a dedicated user account. The user account must be created on the primary server.

When users connect to MaxScale, MaxScale authenticates the user connection before routing it to an Enterprise Server node. Enterprise Server authenticates the connection as originating from the IP address of the MaxScale node.

The application users must have one user account with the host IP address of the application server and a second user account with the host IP address of the MaxScale node.

The requirement of a duplicate user account can be avoided by enabling the `proxy_protocol` parameter for MaxScale and the proxy_protocol_networks for Enterprise Server.

Create a User to Connect from MaxScale

This action is performed on the primary Enterprise ColumnStore node:

1. Connect to the primary Enterprise ColumnStore node:

```
$ sudo mariadb
```

2. Create the database user account for your MaxScale node:

```
CREATE USER 'app_user'@'192.0.2.10' IDENTIFIED BY 'app_user_passwd';
```

Replace 192.0.2.10 with the relevant IP address specification for your MaxScale node.

Passwords should meet your organization's password policies.

3. Grant the privileges required by your application to the database user account for your MaxScale node:

```
GRANT ALL ON test.* TO 'app_user'@'192.0.2.10';
```

The privileges shown are designed to allow the tests in the subsequent sections to work. The user account for your production application may require different privileges.

Create a User to Connect from the Application Server

This action is performed on the primary Enterprise ColumnStore node:

1. Create the database user account for your application server:

```
CREATE USER 'app_user'@'192.0.2.11' IDENTIFIED BY 'app_user_passwd';
```

Replace 192.0.2.11 with the relevant IP address specification for your application server.

Passwords should meet your organization's password policies.

2. Grant the privileges required by your application to the d database user account for your application server:

```
GRANT ALL ON test.* TO 'app_user'@'192.0.2.11';
```

The privileges shown are designed to allow the tests in the subsequent sections to work. The user account for your production application may require different privileges.

Test Connection with Application User

To test the connection, use the MariaDB Client from your application server to connect to an Enterprise ColumnStore node through MaxScale.

This action is performed **on a client connected to the MaxScale node**:

```
$ mariadb --host 192.0.2.10 --port 3307
      --user app_user --password
```

Test Connection with Read Connection Router

If you configured the Read Connection Router, confirm that MaxScale routes connections to the replica servers.

On the MaxScale node, use the maxctrl list listeners command to view the available listeners and ports:

```
$ maxctrl list listeners
```

```
┌─────────────────────────────┬──────┬──────┬─────────┬──────────────────────────┐
│ Name                        │ Port │ Host │ State   │ Service                  │
├─────────────────────────────┼──────┼──────┼─────────┼──────────────────────────┤
│ connection_router_listener  │ 3308 │ ::   │ Running │ connection_router_service │
├─────────────────────────────┼──────┼──────┼─────────┼──────────────────────────┤
│ query_router_listener       │ 3307 │ ::   │ Running │ query_router_service      │
└─────────────────────────────┴──────┴──────┴─────────┴──────────────────────────┘
```

2. Open multiple terminals connected to your application server, in each, use MariaDB Client to connect to the listener port for the Read Connection Router (in the example, 3308):

```
$ mariadb --host 192.0.2.10 --port 3308 \
      --user app_user --password
```

Use the application user credentials you created for the `--user and --password` options.

3. In each terminal, query the hostname and server_id system variable and option to identify to which you're connected:

```
SELECT @@global.hostname, @@global.server_id;

+-------------------+--------------------+
| @@global.hostname | @@global.server_id |
+-------------------+--------------------+
|              mcs2 |                  2 |
+-------------------+--------------------+
```

Different terminals should return different values since MaxScale routes the connections to different nodes.

Since the router was configured with the slave router option, the Read Connection Router only routes connections to replica servers.

Test Write Queries with Read/Write Split Router

If you configured the Read/Write Split Router, confirm that MaxScale routes write queries on this router to the primary Enterprise ColumnStore node.

on the MaxScale node, use the maxctrl list listeners command to view the available listeners and ports:

```
$ maxctrl list listeners
```

```
┌──────────────────────────────┬──────┬──────┬─────────┬──────────────────────────────┐
| Name                         | Port | Host | State   | Service                      |
├──────────────────────────────┼──────┼──────┼─────────┼──────────────────────────────┤
| connection_router_listener | 3308 | ::   | Running | connection_router_service |
├──────────────────────────────┼──────┼──────┼─────────┼──────────────────────────────┤
| query_router_listener      | 3307 | ::   | Running | query_router_service      |
└──────────────────────────────┴──────┴──────┴─────────┴──────────────────────────────┘
```

2. Open multiple terminals connected to your application server, in each, use MariaDB Client to connect to the listener port for the Read/Write Split Router (in the example, 3307):

```
$ mariadb --host 192.0.2.10 --port 3307 \
      --user app_user --password
```

Use the application user credentials you created for the `--user and --password` options.

3. In one terminal, create the test table:

```
CREATE TABLE test.load_balancing_test (
   id INT PRIMARY KEY AUTO_INCREMENT,
   hostname VARCHAR(256),
   server_id INT
);
```

4. In each terminal, issue an insert.md statement to add a row to the example table with the values of the hostname and server_id system variable and option:

```
INSERT INTO test.load_balancing_test (hostname, server_id)
VALUES (@@global.hostname, @@global.server_id);
```

5. In one terminal, issue a SELECT statement to query the results:

```
SELECT * FROM test.load_balancing_test;
```

```
+----+----------+-----------+
| id | hostname | server_id |
+----+----------+-----------+
|  1 | mcs1     |         1 |
|  2 | mcs1     |         1 |
|  3 | mcs1     |         1 |
+----+----------+-----------+
```

While MaxScale is handling multiple connections from different terminals, it routed all connections to the current primary Enterprise ColumnStore node, which in the example is `mcs1#.`

Test Read Queries with Read/Write Split Router

If you configured the Read/Write Split Router (readwritesplit), confirm that MaxScale routes read queries on this router to replica servers.

1. On the MaxScale node, use the maxctrl list listeners command to view the available listeners and ports:

```
$ maxctrl list listeners
```

```
┌──────────────────────────┬──────┬──────┬─────────┬──────────────────────────┐
│ Name                     │ Port │ Host │ State   │ Service                  │
├──────────────────────────┼──────┼──────┼─────────┼──────────────────────────┤
│ connection_router_listener │ 3308 │ ::   │ Running │ connection_router_service │
├──────────────────────────┼──────┼──────┼─────────┼──────────────────────────┤
│ query_router_listener    │ 3307 │ ::   │ Running │ query_router_service     │
└──────────────────────────┴──────┴──────┴─────────┴──────────────────────────┘
```

2. In a terminal connected to your application server, use MariaDB Client to connect to the listener port for the Read/Write Split Router (readwritesplit) (in the example, 3307):

```
$ mariadb --host 192.0.2.10 --port 3307 \
      --user app_user --password
```

Use the application user credentials you created for the –user and –password options.

3. Query the hostname and server_id to identify which server MaxScale routed you to.

```
SELECT @@global.hostname, @@global.server_id;
```

```
+-------------------+--------------------+
| @@global.hostname | @@global.server_id |
+-------------------+--------------------+
|              mcs2 |                  2 |
+-------------------+--------------------+
```

4. Resend the query:

```
SELECT @@global.hostname, @@global.server_id;
```

```
+-------------------+--------------------+
| @@global.hostname | @@global.server_id |
+-------------------+--------------------+
|              mcs3 |                  3 |
+-------------------+--------------------+
```

Confirm that MaxScale routes the SELECT statements to different replica servers.

For more information on different routing criteria, see `slave_selection_criteria`

Next Step

“Deploy ColumnStore Shared Local Storage Topology”.

This page was step 8 of 9.

Next: Step 9: Import Data.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 9: Import Data

Overview

This page details step 9 of the 9-step procedure "Deploy ColumnStore Shared Local Storage Topology".

This step bulk imports data to Enterprise ColumnStore.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Import the Schema

Before data can be imported into the tables, create a matching schema.

On the primary server, create the schema:

1. For each database that you are importing, create the database with the CREATE DATABASE statement:

```
CREATE DATABASE inventory;
```

2. For each table that you are importing, create the table with the CREATE TABLE statement:

```
CREATE TABLE inventory.products (
   product_name VARCHAR(11) NOT NULL DEFAULT '',
   supplier VARCHAR(128) NOT NULL DEFAULT '',
   quantity VARCHAR(128) NOT NULL DEFAULT '',
   unit_cost VARCHAR(128) NOT NULL DEFAULT ''
) ENGINE=Columnstore DEFAULT CHARSET=utf8;
```

Import the Data

Enterprise ColumnStore supports multiple methods to import data into ColumnStore tables.

Interface	Method	Benefits
Shell	cpimport	
SQL	LOAD DATA INFILE	
Remote Database	Remote Database Import	

cpimport

MariaDB Enterprise ColumnStore includes cpimport, which is a command-line utility designed to efficiently load data in bulk. Alternative methods are available.

To import your data from a TSV (tab-separated values) file, on the primary server run cpimport:

```
$ sudo cpimport -s '\t' inventory products /tmp/inventory-products.tsv
```

LOAD DATA INFILE

When data is loaded with the LOAD DATA INFILE statement, MariaDB Enterprise ColumnStore loads the data using cpimport, which is a command-line utility designed to efficiently load data in bulk. Alternative methods are available.

To import your data from a TSV (tab-separated values) file, on the primary server use LOAD DATA INFILE statement:

```
LOAD DATA INFILE '/tmp/inventory-products.tsv'
INTO TABLE inventory.products;
```

Import from Remote Database

MariaDB Enterprise ColumnStore can also import data directly from a remote database. A simple method is to query the table using the SELECT statement, and then pipe the results into cpimport, which is a command-line utility that is designed to efficiently load data in bulk. Alternative methods are available.

To import your data from a remote MariaDB database:

```
$ mariadb --quick \
   --skip-column-names \
   --execute="SELECT * FROM inventory.products" \
   | cpimport -s '\t' inventory products
```

Next Step

Navigation in the procedure “Deploy ColumnStore Shared Local Storage Topology”.

This page was step 9 of 9.

This procedure is complete.

Galera Cluster

Overview

Software Version	Diagram	Features

This procedure describes the deployment of the **Galera Cluster topology** with MariaDB Enterprise Server 11.4 and MariaDB MaxScale 25.01.

MariaDB Enterprise Cluster is powered by Galera.

MariaDB Enterprise Cluster provides read scalability and fault tolerance through virtually synchronous multi-primary certification-based write-set replication (wsrep).

This procedure has 6 steps, which are executed in sequence.

MariaDB products can be deployed in many different topologies to suit specific use cases. Enterprise Cluster can be deployed on its own, or integrated with MariaDB Replication to integrate with other clusters or topologies.

This procedure represents basic product capability with 3 Enterprise Cluster nodes and 1 MaxScale node.

This page provides an overview of the topology, requirements, and deployment procedures.

Please read and understand this procedure before executing.

Procedure Steps

Step	Description
Step 1	Install MariaDB Enterprise Server
Step 2	Start and Configure MariaDB Enterprise Server
Step 3	Test MariaDB Enterprise Server
Step 4	Install MariaDB MaxScale
Step 5	Start and Configure MariaDB MaxScale
Step 6	Test MariaDB MaxScale

Support

Customers can obtain support by submitting a support case.

Components

The following components are deployed during this procedure:

Component	Function
MariaDB Enterprise Server	Modern SQL RDBMS with high availability, pluggable storage engines, hot online backups, and audit logging.
MariaDB MaxScale 25.01	Database proxy that extends the availability, scalability, and security of MariaDB Enterprise Servers

MariaDB Enterprise Server Components

Component	Description
Enterprise Cluster	MariaDB Enterprise Server leverages the Galera Enterprise 4 wsrep provider plugin • Provides virtually synchronous multi-primary replication for MariaDB Enterprise Server • All nodes can handle both reads and writes • Replicates write-sets to all other nodes in the cluster • Supports data-at-rest encryption of the write-set cache
InnoDB	• General purpose storage engine • ACID-compliant • Performance • Required for Enterprise Cluster

MariaDB MaxScale Components

Component	Description
Galera Monitor	Tracks changes in the state of MariaDB Enterprise Servers operating as Enterprise Cluster nodes.
Listener	Listens for client connections to MaxScale, then passes them to the router service associated with the listener
Read Connection Router	Routes connections from the listener to any available Enterprise Cluster node
Read/Write Split Router	Routes read operations from the listener to any available Enterprise Cluster node, and routes write operations from the listener to a specific server that MaxScale uses as the primary server
Server Module	Connection configuration in MaxScale to an Enterprise Cluster node

Topology

MariaDB Enterprise Cluster topology provides read scalability through certification-based write-set replication (wsrep) that is multi-primary and virtually synchronous.

The Enterprise Cluster topology consists of:

- 1 or more MaxScale nodes
- 3 or more MariaDB Enterprise Servers (ES) configured as Enterprise Cluster nodes

The MaxScale nodes:

- Monitor the health and availability of each Enterprise Cluster node using the Galera Monitor (galeramon)
- Accept client and application connections

- Route queries to the Enterprise Cluster nodes using the Read Connection (readconnroute) or the Read/Write Split (readwritesplit) routers.

The Enterprise Cluster nodes:

- Receive queries from MaxScale
- Store data locally using the InnoDB storage engine
- Perform certification-based virtually synchronous replication to other Enterprise Cluster nodes
- Provide State Snapshot Transfers (SST) to bring MariaDB Enterprise Server nodes into sync with the cluster

Requirements

These requirements are for the Galera Cluster topology when deployed with MariaDB Enterprise Server and MariaDB MaxScale 25.01.

- Node Count
- Operating System

Node Count

- MaxScale nodes, 1 or more are required.
- Enterprise Cluster nodes, 3 or more are required.

To avoid problems in establishing a quorum in the event of a network partition or outage, MariaDB recommends deploying an odd number of Enterprise Cluster nodes. When using multiple network switches, deploy across an odd number of switches, each with an odd number of nodes. When using multiple data centers, deploy across an odd number of data centers, each with an odd number of switches.

Operating System

In alignment to the enterprise lifecycle, the Galera Cluster topology with MariaDB Enterprise Server and MariaDB MaxScale 25.01 is provided for:

- AlmaLinux 8 (x86_64, ARM64)
- AlmaLinux 9 (x86_64, ARM64)
- Debian 11 (x86_64, ARM64)
- Debian 12 (x86_64, ARM64)
- Red Hat Enterprise Linux 8 (x86_64, ARM64)
- Red Hat Enterprise Linux 9 (x86_64, PPC64LE, ARM64)
- Red Hat UBI 8 (x86_64, ARM64)
- Rocky Linux 8 (x86_64, ARM64)
- Rocky Linux 9 (x86_64, ARM64)
- SUSE Linux Enterprise Server 15 (x86_64, ARM64)
- Ubuntu 20.04 LTS (x86_64, ARM64)
- Ubuntu 22.04 LTS (x86_64, ARM64)
- Ubuntu 24.04 LTS (x86_64, ARM64)

Quick Reference

MariaDB Enterprise Server Configuration Management

Method	Description
Configuration File	Configuration files (such as `/etc/my.cnf`) can be used to set system-variables and options. The server must be restarted to apply changes made to configuration files.

Method	Description
Command-line	The server can be started with command-line options that set system-variables and options.
SQL	Users can set system-variables that support dynamic changes on-the-fly using the SET statement.

MariaDB Enterprise Server packages are configured to read configuration files from different paths, depending on the operating system. Making custom changes to Enterprise Server default configuration files is not recommended because custom changes may be overwritten by other default configuration files that are loaded later.

To ensure that your custom changes will be read last, create a custom configuration file with the `z-` prefix in one of the include directories.

Distribution	Example Configuration File Path
• CentOS • Red Hat Enterprise Linux (RHEL) • SUSE Linux Enterprise Server (SLES)	`/etc/my.cnf.d/z-custom-mariadb.cnf`
• Debian • Ubuntu	`/etc/mysql/mariadb.conf.d/z-custom-mariadb.cnf`

MariaDB Enterprise Server Service Management

The `systemctl` command is used to start and stop the MariaDB Enterprise Server service. The `galera_new_cluster and galera_recovery` scripts are used for Enterprise Cluster-specific operations.

Operation	Command
Start	`sudo systemctl start mariadb`
Stop	`sudo systemctl stop mariadb`
Restart	`sudo systemctl restart mariadb`
Enable during startup	`sudo systemctl enable mariadb`
Disable during startup	`sudo systemctl disable mariadb`
Status	`sudo systemctl status mariadb`
Bootstrap a cluster node	`sudo galera_new_cluster`
Recover a cluster node's position	`sudo galera_recovery`

For additional information, see "Starting and Stopping MariaDB".

MariaDB Enterprise Server Logs

MariaDB Enterprise Server produces log data that can be helpful in problem diagnosis.

Log filenames and locations may be overridden in the server configuration. The default location of logs is the data directory. The data directory is specified by the datadir system variable.

Log	System Variable/Option	Default Filename
MariaDB Error Log	log_error	`<hostname>.err`
MariaDB Enterprise Audit Log	server_audit_file_path	`server_audit.log`
Slow Query Log	slow_query_log_file	`<hostname>-slow.log`
General Query Log	general_log_file	`<hostname>.log`
Binary Log	log_bin	`<hostname>-bin`

MaxScale Configuration Management

MaxScale can be configured using several methods. These methods make use of MaxScale's REST API.

Method	Benefits
MaxCtrl	Command-line utility to perform administrative tasks through the REST API. See MaxCtrl Commands.
MaxGUI	MaxGUI is a graphical utility that can perform administrative tasks through the REST API.
REST API	The REST API can be used directly. For example, the curl utility could be used to make REST API calls from the command-line. Many programming languages also have libraries to interact with REST APIs.

The procedure on these pages configures MaxScale using MaxCtrl.

MaxScale Service Management

The systemctl command is used to start and stop the MaxScale service.>

Operation	Command
Start	`sudo systemctl start maxscale`
Stop	`sudo systemctl stop maxscale`
Restart	`sudo systemctl restart maxscale`
Enable during startup	`sudo systemctl enable maxscale`
Disable during startup	`sudo systemctl disable maxscale`
Status	`sudo systemctl status maxscale`

For additional information, see "Starting and Stopping MariaDB".

Next Step

Navigation in the procedure "Deploy Galera Cluster Topology":

Next: Step 1: Install MariaDB Enterprise Server

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 1: Install MariaDB Enterprise Server

Overview

This page details step 1 of the 6-step procedure "Deploy Galera Cluster Topology".

This step installs MariaDB Enterprise Server.

MariaDB Enterprise Server installations support MariaDB Enterprise Cluster, powered by Galera. MariaDB Enterprise Cluster uses the Galera Enterprise 4 wsrep provider plugin.

MariaDB Enterprise Cluster requires an odd number of 3 or more nodes. Nodes must meet requirements.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Retrieve Download Token

MariaDB Corporation provides package repositories for CentOS / RHEL (YUM) and Debian / Ubuntu (APT). A download token is required to access the MariaDB Enterprise Repository.

Customer Download Tokens are customer-specific and are available through the MariaDB Customer Portal.

To retrieve the token for your account:

1. Navigate to https://customers.mariadb.com/downloads/token/.
2. Log in.
3. Copy the Customer Download Token.

Substitute your token for `CUSTOMER_DOWNLOAD_TOKEN` when configuring the package repositories.

Set Up Repository

1. On each Enterprise ColumnStore node, install the prerequisites for downloading the software from the Web. Install on CentOS / RHEL (YUM):

```
$ sudo yum install curl
```

Install on Debian / Ubuntu (APT):

```
$ sudo apt install curl apt-transport-https
```

2. On each Enterprise ColumnStore node, configure package repositories and specify Enterprise Server:

```
$ curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
```

```
$ echo "${checksum}  mariadb_es_repo_setup" \
       | sha256sum -c -
```

```
$ chmod +x mariadb_es_repo_setup
```

```
$ sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
      --skip-maxscale \
      --skip-tools \
      --mariadb-server-version="11.4"
```

Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.

Install Enterprise Server

1. On each Enterprise Cluster node, install MariaDB Enterprise Server and MariaDB Enterprise Backup.

Install via CentOS / RHEL (YUM):

```
$ sudo yum install MariaDB-server MariaDB-backup
```

Install via Debian / Ubuntu (APT):

```
$ sudo apt update

$ sudo apt install mariadb-server mariadb-backup
```

Install via SLES (ZYpp):

```
$ sudo zypper install MariaDB-server MariaDB-backup
```

Next Step

Navigation in the procedure “Deploy Galera Cluster Topology”:

This page was step 1 of 6.

Next: Step 2: Start and Configure MariaDB Enterprise Server

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 2: Start and Configure MariaDB Enterprise Server

Overview

This page details step 2 of the 6-step procedure "Deploy Galera Cluster Topology".

This step configures MariaDB Enterprise Servers to operate as Enterprise Cluster nodes and starts MariaDB Enterprise Cluster.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Stop the Enterprise Server Service

The installation process might have started the Enterprise Server service. The service should be stopped prior to making configuration changes.

On each Enterprise Cluster node, stop the MariaDB Enterprise Server service:

```
$ sudo systemctl stop mariadb
```

Acquire TLS Certificate

By default, MariaDB Enterprise Cluster requires data-in-transit encryption to secure Galera replication traffic.

MariaDB Enterprise Cluster encrypts the data using the Transport Layer Security (TLS) protocol, which is a newer version of the Secure Socket Layer (SSL) protocol.

In MariaDB Enterprise Cluster 10.5 and earlier, TLS was supported, but not required. For backward compatibility, MariaDB Enterprise Cluster supports the Provider WSREP TLS Mode, which is equivalent to Enterprise Cluster's TLS implementation in ES 10.5 and earlier. For additional information, see "WSREP TLS Modes".

TLS configuration requires 3 files.

Example Filename	Description
ca-cert.pem	Certificate Authority (CA) file.
server-cert.pem	X.509 certificate file.
server-key.pem	X.509 key file.

Self-signed certificates are supported. However, in environments where security is critical, it is recommended to use certificates signed by a trusted Certificate Authority (CA).

For additional information, see "Data-in-Transit Encryption".

Configure Enterprise Cluster

MariaDB Enterprise Server installations support MariaDB Enterprise Cluster, powered by Galera. MariaDB Enterprise Cluster uses the Galera Enterprise 4 wsrep provider plugin. The path to the wsrep provider plugin must be configured using the wsrep_provider system variable.

Required System Variables and Options

Enterprise Cluster nodes require that you set the following system variables and options:

System Variable/Option	Description
bind_address	The network socket Enterprise Cluster listens on for incoming TCP/IP client connections. On Debian or Ubuntu, this system variable must be set to override the 127.0.0.1 default configuration.
binlog_format	Enterprise Cluster requires use of the ROW Binary Log format.
innodb_autoinc_lock_mode	Enterprise Cluster requires an auto-increment lock mode of 2.
ssl_ca	Certificate Authority (CA) file in PEM format.
ssl_cert	X.509 certificate file in PEM format.
ssl_key	X.509 key file in PEM format.
wsrep_cluster_address	Sets the Group Communications back-end (usually gcomm:), followed by a comma-separated list of IP addresses or domain names for each Cluster Node. It is best practice to include all Enterprise Cluster nodes in this list.
wsrep_cluster_name	Sets the logical name for the cluster. Must be the same on all Cluster Nodes.
wsrep_on	Enables Enterprise Cluster.
wsrep_provider	Path to the Galera Enterprise 4 wsrep provider plugin. In MariaDB Enterprise Cluster 11.4, the path is /usr/lib/galera/libgalera_enterprise_smm.so on Debian and Ubuntu and /usr/lib64/galera/libgalera_enterprise_smm.so on CentOS, RHEL, and SLES.
wsrep_provider_options	Accepts options for the Galera Enterprise 4 wsrep provider plugin. Multiple options can be specified, separated by a semi-colon (;). For example, can be used to configure Galera cache size or to enable TLS. For a complete list of available options, see wsrep_provider_options

Example Configuration

Edit a configuration file and set these system variables and options:

```
[mariadb]
bind_address             = 0.0.0.0
binlog_format            = ROW
innodb_autoinc_lock_mode = 2
wsrep_cluster_address    = gcomm://192.0.2.101,192.0.2.102,192.0.2.103
wsrep_cluster_name       = example-cluster
wsrep_on                 = ON

# wsrep provider path for Debian and Ubuntu:
wsrep_provider = /usr/lib/galera/libgalera_enterprise_smm.so

# wsrep provider path for CentOS, RHEL, and SLES:
# wsrep_provider = /usr/lib64/galera/libgalera_enterprise_smm.so

wsrep_provider_options = "gcache.size=2G;gcs.fc_limit=128"

# TLS Configuration
ssl_ca   = /path/to/ca-cert.pem
ssl_cert = /path/to/sever-cert.pem
ssl_key  = /path/to/server-key.pem
```

For additional information, see “MariaDB Enterprise Server Configuration Management”.

Configure MariaDB Replication

MariaDB Enterprise Cluster can be deployed alongside MariaDB Replication. Deploying MariaDB Enterprise Cluster with MariaDB Replication enables integrating Enterprise Cluster with other products and clusters, for example as

separate clusters in different data centers, or as a small dedicated write cluster with two larger dedicated read clusters.

For additional information, see “Replication Configuration”.

Bootstrap the Primary Component

When an Enterprise Cluster node starts, it checks the addresses in the wsrep_cluster_address system variable to establish connections with other nodes. The node does not become active until it finds a node that belongs to the Primary Component.

To start the cluster when all nodes are down, you must bootstrap the Primary Component on one node. This allows the other nodes to connect to a working cluster.

On one Enterprise Cluster node, when all nodes are down, bootstrap the Primary Component.

1. Bootstrap the Primary Component:

```
$ sudo galera_new_cluster
```

For additional information, see “Bootstrap a Galera Cluster”.

2. Connect with MariaDB Client:

```
$ sudo mariadb
```

The sudo command is used here to connect to the Enterprise Server node using the `root@localhost` user account, which authenticates using the `unix_socket` authentication plugin. Other user accounts can be used by specifying the –user and –password command-line options.

Use the SHOW STATUS statement to check the wsrep_cluster_size status variable:

```
SHOW GLOBAL STATUS LIKE 'wsrep_cluster_size';

+--------------------+-------+
| Variable_name      | Value |
+--------------------+-------+
| wsrep_cluster_size |     1 |
+--------------------+-------+
```

The Enterprise Cluster node launches as the Primary Component of a single-node cluster.

Add Nodes to the Cluster

To add nodes to a cluster that has a Primary Component running, complete the following procedure for each Enterprise Cluster node to be added. Nodes should be added one at a time.

1. On the Enterprise Cluster node being added, start MariaDB Enterprise Server:

```
$ sudo systemctl start mariadb
```

For additional information, see “Start and Stop Services”.

2. On the Enterprise Cluster node being added, connect with MariaDB Client:

```
$ sudo mariadb
```

3. On the bootstrapped Enterprise Cluster node, use the SHOW STATUS statement to check the wsrep_cluster_size status variable:

```
SHOW GLOBAL STATUS LIKE 'wsrep_cluster_size';

+--------------------+-------+
| Variable_name      | Value |
+--------------------+-------+
| wsrep_cluster_size |     2 |
+--------------------+-------+
```

4. On the Enterprise Cluster node being added, use the SHOW STATUS statement to check the wsrep_local_state_comment status variable. If wsrep_local_state_comment is `SYNCED`, the node has been successfully added, and the Add Node procedure can be repeated to add more nodes.

```
SHOW GLOBAL STATUS LIKE 'wsrep_local_state_comment';

+---------------------------+--------+
| Variable_name             | Value  |
+---------------------------+--------+
| wsrep_local_state_comment | Synced |
+---------------------------+--------+
```

When each new Enterprise Cluster node joins the cluster, it requests the current cluster position. If the new node is missing transactions, it initiates either a State Snapshot Transfer (SST) or an Incremental State Transfer (IST) from a donor node to synchronize its data with the Primary Component. Depending on the value of wsrep_sst_method , the donor node may or may not be blocked during an SST.

When the new Enterprise Cluster node finishes its state transfer, the node updates the wsrep_local_state_comment status variable to `SYNCED`. MaxScale registers the change and begins routing connections or queries to the new node.

Next Step

Navigation in the procedure “Deploy Galera Cluster Topology”:

This page was step 2 of 6.

Next: Step 3: Test MariaDB Enterprise Server

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 3: Test MariaDB Enterprise Server

Overview

This page details step 3 of the 6-step procedure “Deploy Galera Cluster Topology”.

This step tests MariaDB Enterprise Server.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Test Enterprise Server Service

Use Systemd to test whether the MariaDB Enterprise Server service is running.

This action is performed on each Enterprise Cluster node.

Check if the MariaDB Enterprise Server service is running by executing the following:

```
$ systemctl status mariadb
```

If the service is not running on any node, start the service by executing the following on that node:

```
$ sudo systemctl start mariadb
```

Test Local Client Connections

Use MariaDB Client to test the local connection to the Enterprise Server node.

This action is performed on each Enterprise Cluster node:

```
$ sudo mariadb

Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 38
Server version: 11.4.5-3-MariaDB-Enterprise MariaDB Enterprise Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]>
```

The sudo command is used here to connect to the Enterprise Server node using the `root@localhost` user account, which authenticates using the `unix_socket` authentication plugin. Other user accounts can be used by specifying the –user and –password command-line options.

Test Cluster Status

MariaDB Enterprise Cluster is operational when the cluster has a Primary Component. Query the wsrep_cluster_status status variable with SHOW GLOBAL STATUS to confirm that each node belongs to the Primary Component.

This action is performed on each Enterprise Cluster node.

Check the cluster status by executing the following:

```
SHOW GLOBAL STATUS LIKE 'wsrep_cluster_status';

+----------------------+---------+
| Variable_name        | Value   |
+----------------------+---------+
| wsrep_cluster_status | Primary |
+----------------------+---------+
```

If the Value column does not contain Primary on any node, then the node is not part of the Primary Component. Investigate network connectivity between the node and the nodes in the Primary Component.

Test Cluster Size

MariaDB Enterprise Cluster maintains a count of the cluster size. Query the wsrep_cluster_size status variable with SHOW GLOBAL STATUS to confirm the number of nodes currently in the cluster.

This action is performed on each Enterprise Cluster node.

Check the cluster size by executing the following:

```
SHOW GLOBAL STATUS LIKE 'wsrep_cluster_size';

+--------------------+---------+
| Variable_name      | Value   |
+--------------------+---------+
| wsrep_cluster_size |       3 |
+--------------------+---------+
```

If the Value column does not contain the expected number of nodes, then some nodes might not be in the cluster. Check the value of the wsrep_cluster_address on each node to confirm that all nodes are in the same cluster.

Test DDL

Use MariaDB Client to test DDL.

1. On a single Enterprise Cluster node, use the MariaDB Client to connect to the node:

```
$ sudo mariadb
```

Create a test database and InnoDB table:

```
CREATE DATABASE IF NOT EXISTS test;

CREATE TABLE test.contacts (
   id INT PRIMARY KEY AUTO_INCREMENT,
   first_name VARCHAR(50),
   last_name VARCHAR(50),
   email VARCHAR(100)
);
```

3. On each other Enterprise Cluster node, use the MariaDB Client to connect to the node:

```
$ sudo mariadb
```

4. Confirm that the database and table exist:

```
SHOW CREATE TABLE test.contacts\G;
```

If the database or table do not exist on any node, then check that:

The nodes are in the Primary Component of the same cluster.

The wsrep_osu_method system variable is not set to RSU.

Test DML

Use MariaDB Client to test DML.

1. On a single Enterprise Cluster node, use the MariaDB Client to connect to the node:

```
$ sudo mariadb
```

2. Insert sample data into the table created in the DDL test:

```
INSERT INTO test.contacts (first_name, last_name, email)
   VALUES
   ("Kai", "Devi", "kai.devi@example.com"),
   ("Lee", "Wang", "lee.wang@example.com");
```

3. On each other Enterprise Cluster node, use the MariaDB Client to connect to the node:

```
$ sudo mariadb
```

4. Execute a SELECT query to retrieve the data:

```
SELECT * FROM test.contacts;

+----+------------+-----------+----------------------+
| id | first_name | last_name | email                |
+----+------------+-----------+----------------------+
| 1  | Kai        | Devi      | kai.devi@example.com |
| 2  | Lee        | Wang      | lee.wang@example.com |
+----+------------+-----------+----------------------+
```

If the data is not returned on any node, then check that:

- The nodes are in the Primary Component of the same cluster.
- The table uses the InnoDB storage engine.
- The wsrep_on system variable is set to ON.

Next Step

Navigation in the procedure “Deploy Galera Cluster Topology”:

This page was step 3 of 6.

Next: Step 4: Install MariaDB MaxScale

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 4: Install MariaDB MaxScale

Overview

This page details step 4 of the 6-step procedure “Deploy Galera Cluster Topology”.

This step installs MariaDB MaxScale.

MariaDB Enterprise Cluster requires 1 or more MaxScale nodes.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Retrieve Customer Download Token

MariaDB Corporation provides package repositories for YUM (RHEL / CentOS), APT (Debian / Ubuntu), and ZYpp (SLES). A download token is required to access the MariaDB Enterprise Repository.

Customer Download Tokens are customer-specific and are available through the MariaDB Customer Portal.

To retrieve the token for your account:

1. Navigate to
2. Log in.
3. Copy the Customer Download Token.

Substitute your token for `CUSTOMER_DOWNLOAD_TOKEN` when configuring the package repositories.

Set Up Repository

1. On the MaxScale node, install the prerequisites for downloading the software from the Web.

Install on CentOS / RHEL (YUM):

```
$ sudo yum install curl
```

Install on Debian / Ubuntu (APT):

```
$ sudo apt install curl apt-transport-https
```

Install on SLES (ZYpp):

```
$ sudo zypper install curl
```

2. On the MaxScale node, configure package repositories and specify MariaDB MaxScale 25.01:

```
$ curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup

$ echo "${checksum}  mariadb_es_repo_setup" \
       | sha256sum -c -

$ chmod +x mariadb_es_repo_setup

$ sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
      --skip-server \
      --skip-tools \
      --mariadb-maxscale-version="25.01"
```

Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.

Install MaxScale

1. On the MaxScale node, install MariaDB MaxScale.

Install on CentOS / RHEL (YUM):

```
$ sudo yum install maxscale
```

Install on Debian / Ubuntu (APT):

```
$ sudo apt install maxscale
```

Install on SLES (ZYpp):

```
$ sudo zypper install maxscale
```

Next Step

Navigation in the procedure “Deploy Galera Cluster Topology”:

This page was step 4 of 6.

Step 5: Start and Configure MariaDB MaxScale

Overview

This page details step 5 of the 6-step procedure “Deploy Galera Cluster Topology”.

This step configures MariaDB MaxScale to route connections to MariaDB Enterprise Cluster.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Replace the Default Configuration File

MariaDB MaxScale installations include a configuration file with some example objects. This configuration file should be replaced.

On the MaxScale node, replace the default /etc/maxscale.cnf with the following configuration:

```
[maxscale]
threads          = auto
admin_host       = 0.0.0.0
admin_secure_gui = false
```

For additional information, see “Global Parameters”.

Restart MaxScale

On the MaxScale node, restart the MaxScale service to ensure that MaxScale picks up the new configuration:

```
$ sudo systemctl restart maxscale
```

For additional information, see “Start and Stop Services”.

Create MaxScale User Account

MariaDB MaxScale connects to Enterprise Cluster through the client port. MaxScale requires its own user account to monitor and orchestrate Enterprise Cluster nodes.

1. On any Enterprise Cluster node, use the CREATE USER statement to create a new user for MaxScale:

```
CREATE USER mxs@192.0.2.104 IDENTIFIED BY "passwd";
```

2. Use the GRANT statement to grant required privileges to the MaxScale user:

```
GRANT SHOW DATABASES ON *.* TO mxs@192.0.2.104;
GRANT SELECT ON mysql.columns_priv TO mxs@192.0.2.104;
GRANT SELECT ON mysql.db TO mxs@192.0.2.104;
GRANT SELECT ON mysql.procs_priv TO mxs@192.0.2.104;
GRANT SELECT ON mysql.proxies_priv TO mxs@192.0.2.104;
GRANT SELECT ON mysql.roles_mapping TO mxs@192.0.2.104;
GRANT SELECT ON mysql.tables_priv TO mxs@192.0.2.104;
GRANT SELECT ON mysql.user TO mxs@192.0.2.104;
```

Enterprise Cluster replicates the new user and privileges to the other Enterprise Cluster nodes.

Configure Server Objects

MariaDB MaxScale uses server objects to define the connections it makes to MariaDB Enterprise Servers.

On the MaxScale node, use maxctrl create server to create a server object for each MariaDB Enterprise Server:

```
$ maxctrl create server node1 192.0.2.101

$ maxctrl create server node2 192.0.2.102

$ maxctrl create server node3 192.0.2.103
```

Configure the Galera Monitor

MaxScale uses monitors to retrieve additional information from the servers. This information is used by other services in filtering and routing connections based on the current state of the node. For Enterprise Cluster, use the Galera Monitor (galeramon).

On the MaxScale node, use maxctrl create monitor to create a Galera Monitor for the cluster:

```
$ maxctrl create monitor cluster_monitor galeramon \
     user=mxs \
     password='MAXSCALE_USER_PASSWORD' \
     --servers node1 node2 node3
```

In this example:

- `cluster_monitor` is an arbitrary name that is used to identify the new monitor.
- `galeramon` is the name of the module that implements the Galera Monitor.
- `user=MAXSCALE_USER` sets the user parameter to the database user account that MaxScale uses to monitor the ES nodes.
- `password='MAXSCALE_USER_PASSWORD'` sets the password parameter to the password used by the database user account that MaxScale uses to monitor the ES nodes.
- `--servers sets the servers` parameter to the set of nodes that MaxScale should monitor. All non-option arguments after –servers are interpreted as server names.
- Other Module Parameters supported by galeramon in MaxScale 25.01 can also be specified.

Choose a MaxScale Router

Routers control how MaxScale balances the load between Enterprise Cluster nodes. Each router uses a different approach to routing queries. Consider the specific use case of your application and database load and select the router that best suits your needs.

Router	Configuration Procedure	Description
Read Connection (readconnroute)	Configure Read Connection Router	• Connection-based load balancing • Routes connections to Enterprise ColumnStore nodes designated as replica servers for a read-only pool • Routes connections to an Enterprise ColumnStore node designated as the primary server for a read-write pool.
Read/Write Split (readwritesplit)	Configure Read/Write Split	• Query-based load balancing • Routes write queries to an Enterprise ColumnStore node designated as the primary server • Routes read queries to Enterprise ColumnStore node designated as replica servers • Automatically reconnects after node failures • Automatically replays transactions after node failures • Optionally enforces causal reads

Configure Read Connection Router

Use MaxScale Read Connection Router (readconnroute) to route connections to replica servers for a read-only pool.

On the MaxScale node, use maxctrl create service to create a router:

```
$ maxctrl create service connection_router_service readconnroute \
     user=mxs \
     password='MAXSCALE_USER_PASSWORD' \
     router_options=slave \
     --servers node1 node2 node3
```

In this example:

- `connection_router_service` is an arbitrary name that is used to identify the new service.
- `readconnroute` is the name of the module that implements the Read Connection Router.
- `user=MAXSCALE_USER` sets the user parameter to the database user account that MaxScale uses to connect to the ES nodes.

- `password=MAXSCALE_USER_PASSWORD` sets the password parameter to the password used by the database user account that MaxScale uses to connect to the ES nodes.
- `router_options=slave` sets the router_options parameter to slave, so that MaxScale only routes connections to the replica nodes.
- `--servers sets the servers` parameter to the set of nodes to which MaxScale should route connections. All non-option arguments after `--servers` are interpreted as server names.
- Other Module Parameters supported by readconnroute in MaxScale 25.01 can also be specified.

Configure Listener for the Read Connection Router

These instructions reference TCP port 3308. You can use a different TCP port. The TCP port used must not be bound by any other listener.

On the MaxScale node, use the maxctrl create listener command to configure MaxScale to use a listener for the Read Connection Router (readconnroute):

```
$ maxctrl create listener connection_router_service connection_router_listener 3308 \
     protocol=MariaDBClient
```

In this example:

- `connection_router_service` is the name of the readconnroute service that was previously created.
- `connection_router_listener` is an arbitrary name that is used to identify the new listener.
- 3308 is the TCP port.
- `protocol=MariaDBClient` sets the protocol parameter.
- Other Module Parameters supported by listeners in MaxScale 25.01 can also be specified.

Configure Read/Write Split Router for Queries

MaxScale Read/Write Split Router (readwritesplit) performs query-based load balancing. The router routes write queries to the primary and read queries to the replicas.

On the MaxScale node, use the maxctrl create service command to configure MaxScale to use the Read/Write Split Router (readwritesplit):

```
$ maxctrl create service query_router_service readwritesplit  \
     user=mxs \
     password='MAXSCALE_USER_PASSWORD' \
     --servers node1 node2 node3
```

In this example:

- `query_router_service` is an arbitrary name that is used to identify the new service.
- `readwritesplit` is the name of the module that implements the Read/Write Split Router.
- `user=MAXSCALE_USER` sets the user parameter to the database user account that MaxScale uses to connect to the ES nodes.
- `password=MAXSCALE_USER_PASSWORD` sets the password parameter to the password used by the database user account that MaxScale uses to connect to the ES nodes.
- `--servers sets the servers` parameter to the set of nodes to which MaxScale should route queries. All non-option arguments after –servers are interpreted as server names.
- Other Module Parameters supported by readwritesplit in MaxScale 25.01 can also be specified.

Configure a Listener for the Read/Write Split Router

These instructions reference TCP port 3307. You can use a different TCP port. The TCP port used must not be bound by any other listener.

On the MaxScale node, use the maxctrl create listener command to configure MaxScale to use a listener for the Read/Write Split Router (readwritesplit):

```
$ maxctrl create listener query_router_service query_router_listener 3307 \
     protocol=MariaDBClient
```

In this example:

- `query_router_service` is the name of the readwritesplit service that was previously created.
- `query_router_listener` is an arbitrary name that is used to identify the new listener.
- 3307 is the TCP port.
- `protocol=MariaDBClient` sets the protocol parameter.
- Other Module Parameters supported by listeners in MaxScale 25.01 can also be specified.

Start Services

To start the services and monitors, on the MaxScale node use maxctrl start services:

```
$ maxctrl start services
```

Next Step

Navigation in the procedure “Deploy Galera Cluster Topology”:

This page was step 5 of 6.

Next: Step 6: Test MariaDB MaxScale

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 6: Test MariaDB MaxScale

Overview

This page details step 6 of the 6-step procedure “Deploy Galera Cluster Topology”.

This step tests MariaDB MaxScale.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Check Global Configuration

Use maxctrl show maxscale command to view the global MaxScale configuration.

This action is performed on the MaxScale node:

```
$ maxctrl show maxscale
```

```

└──────────────┴─────────────────────────────────────────────────────────┘
```

Output should align to the global MaxScale configuration in the new configuration file you created.

Check Server Configuration

Use the maxctrl list servers and maxctrl show server commands to view the configured server objects.

This action is performed on the MaxScale node:

1. Obtain the full list of servers objects:

```
$ maxctrl list servers
```

```
┌────────┬─────────────┬──────┬─────────────┬─────────────────────────┬──────┐
| Server | Address     | Port | Connections | State                   | GTID |
├────────┼─────────────┼──────┼─────────────┼─────────────────────────┼──────┤
| node1  | 192.0.2.101 | 3306 | 0           | Slave, Synced, Running  |      |
├────────┼─────────────┼──────┼─────────────┼─────────────────────────┼──────┤
| node2  | 192.0.2.102 | 3306 | 0           | Slave, Synced, Running  |      |
├────────┼─────────────┼──────┼─────────────┼─────────────────────────┼──────┤
| node3  | 192.0.2.103 | 3306 | 0           | Master, Synced, Running |      |
└────────┴─────────────┴──────┴─────────────┴─────────────────────────┴──────┘
```

2. For each server object, view the configuration:

```
$ maxctrl show server node3
```

```
┌──────────────────┬──────────────────────────────────────────────────────────────┐
│ Server           │ node3                                                        │
├──────────────────┼──────────────────────────────────────────────────────────────┤
│ Address          │ 192.0.2.103                                                  │
├──────────────────┼──────────────────────────────────────────────────────────────┤
│ Port             │ 3306                                                         │

```

Output should align to the Server Object configuration you performed.

Check Monitor Configuration

Use the maxctrl list monitors and maxctrl show monitor commands to view the configured monitors.

This action is performed on the MaxScale node:

1. Obtain the full list of monitors:

```
$ maxctrl list monitors
```

```
┌─────────────────┬─────────┬──────────────────────┐
│ Monitor         │ State   │ Servers              │
├─────────────────┼─────────┼──────────────────────┤
│ cluster_monitor │ Running │ node1, node2, node3 │
└─────────────────┴─────────┴──────────────────────┘
```

2. For each monitor, view the monitor configuration:

```
$ maxctrl show monitor cluster_monitor
```

```
┌──────────────────┬──────────────────────────────────────────────────────────┐
│ Monitor          │ cluster_monitor                                          │

│                  │ }                                                        │
└──────────────────┴──────────────────────────────────────────────────────────┘
```

Output should align to the Galera Monitor (galeramon) configuration you performed.

Check Service Configuration

Use the maxctrl list services and maxctrl show service commands to view the configured routing services.

This action is performed on the MaxScale node:

1. Obtain the full list of routing services:

```
$ maxctrl list services
```

```
┌──────────────────────────┬──────────────┬─────────────┬─────────────────┬──────────────────┐
│ Service                  │ Router       │ Connections │ Total Connections │ Servers          │
├──────────────────────────┼──────────────┼─────────────┼─────────────────┼──────────────────┤
│ connection_router_service │ readconnroute │ 0           │ 0               │ node1, node2, node3 │
├──────────────────────────┼──────────────┼─────────────┼─────────────────┼──────────────────┤
│ query_router_service     │ readwritesplit │ 1           │ 1               │ node1, node2, node3 │
└──────────────────────────┴──────────────┴─────────────┴─────────────────┴──────────────────┘
```

2. For each service, view the service configuration:

```
$ maxctrl show service query_router_service
```

```
┌────────────────────┬──────────────────────────────────────────────────────────────────────────────┐
│ Service            │ query_router_service                                                         │

|                      |     ]                                                              |
|                      | }                                                                  |
└──────────────────────┴────────────────────────────────────────────────────────────────────┘
```

Output should align to the Read Connection Router (readconnroute) or Read/Write Split Router (readwritesplit) configuration you performed.

Test Application User

Applications should use a dedicated user account. The user account must be created on the primary server.

When users connect to MaxScale, MaxScale authenticates the user connection before routing it to an Enterprise Server node. Enterprise Server authenticates the connection as originating from the IP address of the MaxScale node.

The application users must have one user account with the host IP address of the application server and a second user account with the host IP address of the MaxScale node.

The requirement of a duplicate user account can be avoided by enabling the `proxy_protocol` parameter for MaxScale and the proxy_protocol_networks for Enterprise Server.

Create a User to Connect from MaxScale

This action is performed on any Enterprise Cluster node:

1. Connect to the node:

```
$ sudo mariadb
```

2. Create the database user account for your MaxScale node:

```
CREATE USER 'app_user'@'192.0.2.104' IDENTIFIED BY 'app_user_passwd';
```

Replace 192.0.2.104 with the relevant IP address specification for your MaxScale node.

Passwords should meet your organization's password policies.

3. Grant the privileges required by your application to the database user account for your MaxScale node:

```
GRANT ALL ON test.* TO 'app_user'@'192.0.2.104';
```

The privileges shown are designed to allow the tests in the subsequent sections to work. The user account for your production application may require different privileges.

Create a User to Connect from the Application Server

This action is performed on any Enterprise Cluster node:

1. Create the database user account for your application server:

```
CREATE USER 'app_user'@'192.0.2.11' IDENTIFIED BY 'app_user_passwd';
```

Replace 192.0.2.11 with the relevant IP address specification for your application server.

Passwords should meet your organization's password policies.

2. Grant the privileges required by your application to the database user account for your application server:

```
GRANT ALL ON test.* TO 'app_user'@'192.0.2.11';
```

The privileges shown are designed to allow the tests in the subsequent sections to work. The user account for your production application may require different privileges.

Test Connection with Application User

To test the connection, use the MariaDB Client from your application server to connect to an Enterprise Cluster node through MaxScale.

This action is performed on the application server:

```
$ mariadb --host 192.0.2.104 --port 3307
      --user app_user --password
```

Test Connection with Read Connection Router

If you configured the Read Connection Router, confirm that MaxScale routes connections to the replica servers.

1. On the MaxScale node, use the maxctrl list listeners command to view the available listeners and ports:

```
$ maxctrl list listeners
```

```
┌──────────────────────────┬──────┬──────┬─────────┬──────────────────────────┐
│ Name                     │ Port │ Host │ State   │ Service                  │
├──────────────────────────┼──────┼──────┼─────────┼──────────────────────────┤
│ connection_router_listener │ 3308 │ ::   │ Running │ connection_router_service │
├──────────────────────────┼──────┼──────┼─────────┼──────────────────────────┤
│ query_router_listener    │ 3307 │ ::   │ Running │ query_router_service     │
└──────────────────────────┴──────┴──────┴─────────┴──────────────────────────┘
```

2. Open multiple terminals connected to your application server, in each use MariaDB Client to connect to the listener port for the Read Connection Router (in the example 3308):

```
$ mariadb --host 192.0.2.104 --port 3308 \
      --user app_user --password
```

Use the application user credentials you created for the `--user` and `--password` options.

3. In each terminal, query the hostname system variable to identify to which you're connected:

```
SELECT @@global.hostname;

+-------------------+
| @@global.hostname |
+-------------------+
|             node2 |
+-------------------+
```

Different terminals should return different values since MaxScale routes the connections to different nodes.

Since the router was configured the slave router option, the Read Connection Router only routes connections to replica servers.

Test Write Queries with the Read/Write Split Router

If you configured the Read/Write Split Router, confirm that readwritesplit correctly routes write queries.

This action is performed with multiple client connections to the MaxScale node.

1. On the MaxScale node, use the maxctrl list servers command to identify the Enterprise Cluster node currently operating as the primary server:

```
$ maxctrl list servers
```

```
┌────────┬───────────────┬──────┬─────────────┬─────────────────────────┬──────┐
│ Server │ Address       │ Port │ Connections │ State                   │ GTID │
├────────┼───────────────┼──────┼─────────────┼─────────────────────────┼──────┤
│ node1  │ 192.0.2.101 │ 3306 │ 0           │ Slave, Synced, Running  │      │
├────────┼───────────────┼──────┼─────────────┼─────────────────────────┼──────┤
│ node2  │ 192.0.2.102 │ 3306 │ 0           │ Slave, Synced, Running  │      │
├────────┼───────────────┼──────┼─────────────┼─────────────────────────┼──────┤
│ node3  │ 192.0.2.103 │ 3306 │ 0           │ Master, Synced, Running │      │
└────────┴───────────────┴──────┴─────────────┴─────────────────────────┴──────┘
```

The server listed as Master is currently operating as the primary server.

2. On the MaxScale node, use the maxctrl list listeners command to identify the correct listener port:

```
$ maxctrl list listeners galerarouter
```

```
┌─────────────────────────────┬──────┬──────┬─────────┬──────────────────────────────┐
│ Name                        │ Port │ Host │ State   │ Service                      │
├─────────────────────────────┼──────┼──────┼─────────┼──────────────────────────────┤
│ connection_router_listener │ 3308 │      │ Running │ connection_router_service │
│ query_router_listener      │ 3307 │      │ Running │ query_router_service      │
└─────────────────────────────┴──────┴──────┴─────────┴──────────────────────────────┘
```

In the example, the listener port for the Read/Write Split router is 3307.

3. Use the MariaDB Client to establish multiple connections to the listener configured for the Read/Write Split routing service, `query_router_listener`, on the MaxScale node:

```
$ mariadb --host=192.0.2.104 --port=3307 \
      --user=app_user --password=app_user_passwd
```

The database user account for your application server should be specified by the `--user` option.

4. Using any client connection, create a test table:

```
CREATE TABLE test.load_balancing_test (
   id INT PRIMARY KEY AUTO_INCREMENT,
   hostname VARCHAR(256)
);
```

5. Using each client connection, insert the values of the hostname system variable into the table using the INSERT statement to identify the node that executes the statement:

```
INSERT INTO test.load_balancing_test (hostname)
VALUES (@@global.hostname);
```

6. Using any client connection, query the table using the SELECT statement:

```
SELECT * FROM test.load_balancing_test;
```

```
+----+----------+
| id | hostname |
+----+----------+
|  1 | node3    |
|  4 | node3    |
|  7 | node3    |
+----+----------+
```

The output shows the hostname from the Enterprise Cluster node operating as the primary server. (Enterprise Cluster offsets auto-increment values by node to avoid write conflicts.)

Confirm that MaxScale is routing write queries to the Enterprise Cluster node operating as the primary server by checking that the test table only contains the hostname of the correct Enterprise Cluster node.

Test Read Queries with the Read/Write Split Router

If you configured the Read/Write Split Router, confirm that readwritesplit properly routes read queries to multiple replica servers.

This action is performed with multiple clients connected to the MaxScale node.

1. On the MaxScale node, use maxctrl list servers to identify the Enterprise Cluster nodes that are currently operating as replica servers:

```
$ maxctrl list servers
```

```
┌────────┬─────────────┬──────┬─────────────┬─────────────────────────┬──────┐
│ Server │ Address     │ Port │ Connections │ State                   │ GTID │
├────────┼─────────────┼──────┼─────────────┼─────────────────────────┼──────┤
│ node1  │ 192.0.2.101 │ 3306 │ 0           │ Slave, Synced, Running  │      │
├────────┼─────────────┼──────┼─────────────┼─────────────────────────┼──────┤
│ node2  │ 192.0.2.102 │ 3306 │ 0           │ Slave, Synced, Running  │      │
├────────┼─────────────┼──────┼─────────────┼─────────────────────────┼──────┤
│ node3  │ 192.0.2.103 │ 3306 │ 0           │ Master, Synced, Running │      │
└────────┴─────────────┴──────┴─────────────┴─────────────────────────┴──────┘
```

The servers listed as Slave are currently operating as replica servers.

2. On the MaxScale node, use the maxctrl list listeners command to identify the correct listener port:

```
$ maxctrl list listeners
```

```
┌──────────────────────────────┬──────┬──────┬─────────┬──────────────────────────┐
| Name                         | Port | Host | State   | Service                  |
├──────────────────────────────┼──────┼──────┼─────────┼──────────────────────────┤
| connection_router_listener | 3308 |      | Running | connection_router_service |
| query_router_listener      | 3307 |      | Running | query_router_service      |
└──────────────────────────────┴──────┴──────┴─────────┴──────────────────────────┘
```

In the example, the listener port for the Read/Write Split router is 3307.

3. Use the MariaDB Client to establish multiple connections to `query_router_listener` which is the listener configured for the Read/Write Split routing service on the MaxScale node:

```
$ mariadb --host=192.0.2.104 --port=3307 \
   --user=app_user --password=app_user_passwd
```

The database user account for your application server should be specified by the –user option.

4. Using each client connection, query the hostname system variable to identify the node that executes the statement:

```
SELECT @@global.hostname;

+-------------------+
| @@global.hostname |
+-------------------+
|             node2 |
+-------------------+
```

The output shows the hostname value from one of the Enterprise Cluster nodes operating as replica servers.

Confirm that MaxScale is routing read queries to multiple Enterprise Cluster nodes operating as replica servers by checking that different client connections return different hostname values.

For more information on different routing criteria, `slave_selection_criteria`

Next Step

Navigation in the procedure “Deploy Galera Cluster Topology”:

This page was step 6 of 6.

This procedure is complete.

HTAP

Overview

Software Version	Diagram	Features
• Enterprise Server 10.5 • Enterprise Server 10.6 • Enterprise Server 11.4		**Single-stack hybrid transactional/analytical workloads** • ColumnStore for analytics with scalable S3-compatible object storage • InnoDB for transactions • Cross-engine JOINs • Enterprise Server 10.5, Enterprise ColumnStore 5, MaxScale 2.5 • Enterprise Server 10.6, Enterprise ColumnStore 23.02, MaxScale 22.08

This procedure describes the deployment of the **HTAP topology** with MariaDB Enterprise Server and MariaDB Enterprise ColumnStore.

MariaDB Enterprise ColumnStore is a columnar storage engine for MariaDB Enterprise Server. This topology is best suited for Hybrid Transactional-Analytical Processing (HTAP) workloads.

This procedure has 4 steps, which are executed in sequence.

This procedure represents the basic product capability and uses 1 Enterprise ColumnStore node.

This page provides an overview of the topology, requirements, and deployment procedures.

Please read and understand this procedure before executing.

Procedure Steps

Step	Description
Step 1	Prepare ColumnStore Node
Step 2	Install MariaDB Enterprise Server
Step 3	Start and Configure MariaDB Enterprise Server
Step 4	Test MariaDB Enterprise Server

Support

Customers can obtain support by submitting a support case.

Components

The following components are deployed during this procedure:

Component	Function
MariaDB Enterprise Server	Modern SQL RDBMS with high availability, pluggable storage engines, hot online backups, and audit logging.

MariaDB Enterprise Server Components

Component	Description
InnoDB	• General purpose storage engine • Support for Online Transactional Processing (OLTP) workloads • ACID-compliant • Performance
MariaDB Enterprise ColumnStore	• Columnar storage engine • Optimized for Online Analytical • Processing (OLAP) workloads • Scalable query execution

Topology

The MariaDB Enterprise ColumnStore HTAP topology is designed for hybrid transactional-analytical processing (HTAP) workloads.

The topology consists of:

- One MaxScale node
- One ColumnStore node running ES and Enterprise ColumnStore

The MaxScale node:

- Monitors the health and availability of the ColumnStore node using the MariaDB Monitor (mariadbmon)
- Accepts client and application connections

- Routes queries to the ColumnStore node using the Read/Write Split Router (readwritesplit)

The ColumnStore node:

- Receives queries from MaxScale
- Executes queries
- Uses a row-based storage engine, such as InnoDB to handle transactional queries
- Uses Enterprise ColumnStore as the columnar storage engine to handle analytical queries
- Uses cross-engine JOINs to join transactional and analytical tables
- Replicates data between engines using MariaDB Replication
- Optionally uses S3-compatible object storage for Enterprise ColumnStore data

Requirements

These requirements are for the HTAP topology when deployed with MariaDB Enterprise Server 11.4 and MariaDB Enterprise ColumnStore.

- Operating System
- S3-Compatible Object Storage Option
- Preferred Object Storage Providers: Cloud
- Preferred Object Storage Providers: Hardware

Operating System

In alignment to the enterprise lifecycle, the HTAP topology with MariaDB Enterprise Server 11.4 and MariaDB Enterprise ColumnStore is provided for:

- Debian 11 (x86_64, ARM64)
- Debian 12 (x86_64, ARM64)
- Red Hat Enterprise Linux 8 (x86_64, ARM64)
- Red Hat Enterprise Linux 9 (x86_64, ARM64)
- Rocky Linux 8 (x86_64, ARM64)
- Rocky Linux 9 (x86_64, ARM64)
- Ubuntu 20.04 LTS (x86_64, ARM64)
- Ubuntu 22.04 LTS (x86_64, ARM64)
- Ubuntu 24.04 LTS (x86_64, ARM64)

S3-Compatible Object Storage Option

The HTAP topology can use S3-compatible object storage to store ColumnStore data, but it is not required.

Many S3-compatible object storage services exist. MariaDB Corporation cannot make guarantees about all S3-compatible object storage services, because different services provide different functionality.

For the preferred S3-compatible object storage providers that provide cloud and hardware solutions, see the following sections:

- Cloud
- Hardware

The use of non-cloud and non-hardware providers is at your own risk.

If you have any questions about using specific S3-compatible object storage with MariaDB Enterprise ColumnStore, contact us.

Preferred Object Storage Providers: Cloud

- Amazon Web Services (AWS) S3
- Google Cloud Storage
- Azure Storage
- Alibaba Cloud Object Storage Service

Preferred Object Storage Providers: Hardware

- Cloudian HyperStore
- Dell EMC
- Seagate Lyve Rack
- Quantum ActiveScale
- IBM Cloud Object Storage

Limitations

Cross-Database Queries

This implementation relies on replicate_rewrite_db, so it does not support cross-database queries with statement-based replication.

For example, if the replicated database is selected by the USE, then the query will replicate properly:

```
USE innodb_db;

INSERT INTO htap_test1
   VALUES (100);
```

```
SELECT * FROM columnstore_db.htap_test1;

+------+
| id   |
+------+
|  100 |
+------+
```

However, if the replicated database is not selected, and it is instead prefixed the table name in the query, then the query will *not* replicate properly:

```
USE columnstore_db;

INSERT INTO innodb_db.htap_test1
   VALUES (200);
```

```
SELECT * FROM columnstore_db.htap_test1;

+------+
| id   |
+------+
|  100 |
+------+
```

Semi-Synchronous Replication

This implementation has not been tested with semi-synchronous replication.

Parallel Replication

This implementation has not been tested with parallel replication.

Row-Based Replication

This implementation requires the binlog_format system variable to be set to `STATEMENT`. Row-based replication is not currently supported.

Quick Reference

MariaDB Enterprise Server Configuration Management

Method	Description
Configuration File	Configuration files (such as /etc/my.cnf) can be used to set system-variables and options. The server must be restarted to apply changes made to configuration files.
Command-line	The server can be started with command-line options that set system-variables and options.
SQL	Users can set system-variables that support dynamic changes on-the-fly using the SET statement.

MariaDB Enterprise Server packages are configured to read configuration files from different paths, depending on the operating system. Making custom changes to Enterprise Server default configuration files is not recommended because custom changes may be overwritten by other default configuration files that are loaded later.

To ensure that your custom changes will be read last, create a custom configuration file with the z- prefix in one of the include directories.

Distribution	Example Configuration File Path
• CentOS • Red Hat Enterprise Linux (RHEL)	/etc/my.cnf.d/z-custom-mariadb.cnf
• Debian • Ubuntu	/etc/my.cnf.d/z-custom-mariadb.cnf

MariaDB Enterprise Server Service Management

The systemctl command is used to start and stop the MariaDB Enterprise Server service.

Operation	Command
Start	`sudo systemctl start mariadb`
Stop	`sudo systemctl stop mariadb`
Restart	`sudo systemctl restart mariadb`
Enable during startup	`sudo systemctl enable mariadb`
Disable during startup	`sudo systemctl disable mariadb`
Status	`sudo systemctl status mariadb`

For additional information, see “Starting and Stopping MariaDB”.

MariaDB Enterprise Server Logs

MariaDB Enterprise Server produces log data that can be helpful in problem diagnosis.

Log filenames and locations may be overridden in the server configuration. The default location of logs is the data directory. The data directory is specified by the datadir system variable.

Log	System Variable/Option	Default Filename
MariaDB Error Log	log_error	`<hostname>.err`
MariaDB Enterprise Audit Log	server_audit_file_path	`server_audit.log`
Slow Query Log	slow_query_log_file	`<hostname>-slow.log`
General Query Log	general_log_file	`<hostname>.log`
Binary Log	log_bin	`<hostname>-bin`

Enterprise ColumnStore Service Management

The systemctl command is used to start and stop the ColumnStore service.

Operation	Command
Start	`sudo systemctl start mariadb-columnstore`
Stop	`sudo systemctl stop mariadb-columnstore`
Restart	`sudo systemctl restart mariadb-columnstore`
Enable during startup	`sudo systemctl enable mariadb-columnstore`
Disable during startup	`sudo systemctl disable mariadb-columnstore`
Status	`sudo systemctl status mariadb-columnstore`

Next Step

Navigation in the procedure “Deploy HTAP Topology”.

Next: Step 1: Prepare ColumnStore Node.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 1: Prepare ColumnStore Node

Overview

This page details step 1 of the 4-step procedure “Deploy HTAP Topology”.

This step prepares the system to host MariaDB Enterprise Server and MariaDB Enterprise ColumnStore 23.10.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Optimize Linux Kernel Parameters

MariaDB Enterprise ColumnStore performs best with Linux kernel optimizations.

To optimize the kernel:

1. Set the relevant kernel parameters in a sysctl configuration file. To ensure proper change management, use an Enterprise ColumnStore-specific configuration file.

Create `a /etc/sysctl.d/90-mariadb-enterprise-columnstore.conf` file:

```
# minimize swapping
vm.swappiness = 1

# Increase the TCP max buffer size
net.core.rmem_max = 16777216
net.core.wmem_max = 16777216

# Increase the TCP buffer limits
# min, default, and max number of bytes to use
net.ipv4.tcp_rmem = 4096 87380 16777216
net.ipv4.tcp_wmem = 4096 65536 16777216

# don't cache ssthresh from previous connection
net.ipv4.tcp_no_metrics_save = 1

# for 1 GigE, increase this to 2500
# for 10 GigE, increase this to 30000
net.core.netdev_max_backlog = 2500
```

2. Use the sysctl command to set the kernel parameters at runtime

```
$ sudo sysctl --load=/etc/sysctl.d/90-mariadb-enterprise-columnstore.conf
```

Temporarily Configure Linux Security Modules (LSM)

The Linux Security Modules (LSM) should be temporarily disabled on each Enterprise ColumnStore node during installation.

The LSM will be configured and re-enabled later in this deployment procedure.

The steps to disable the LSM depend on the specific LSM used by the operating system.

CentOS / RHEL Stop SELinux

SELinux must be set to permissive mode before installing MariaDB Enterprise ColumnStore.

To set SELinux to permissive mode:

1. Set SELinux to permissive mode:

```
$ sudo setenforce permissive
```

2. Set SELinux to permissive mode by setting SELINUX=permissive in /etc/selinux/config.

For example, the file will usually look like this after the change:

```
# This file controls the state of SELinux on the system.
# SELINUX= can take one of these three values:
#     enforcing - SELinux security policy is enforced.
#     permissive - SELinux prints warnings instead of enforcing.
#     disabled - No SELinux policy is loaded.
SELINUX=permissive
# SELINUXTYPE= can take one of three values:
#     targeted - Targeted processes are protected,
#     minimum - Modification of targeted policy. Only selected processes are protected.
#     mls - Multi Level Security protection.
SELINUXTYPE=targeted
```

3. Confirm that SELinux is in permissive mode:

```
$ sudo getenforce
Permissive
```

SELinux will be configured and re-enabled later in this deployment procedure. This configuration is not persistent. If you restart the server before configuring and re-enabling SELinux later in the deployment procedure, you must reset the enforcement to permissive mode.

Debian / Ubuntu AppArmor

AppArmor must be disabled before installing MariaDB Enterprise ColumnStore.

1. Disable AppArmor:

```
$ sudo systemctl disable apparmor
```

2. Reboot the system.
3. Confirm that no AppArmor profiles are loaded using aa-status:

```
$ sudo aa-status

apparmor module is loaded.
0 profiles are loaded.
0 profiles are in enforce mode.
0 profiles are in complain mode.
0 processes have profiles defined.
0 processes are in enforce mode.
0 processes are in complain mode.
0 processes are unconfined but have a profile defined.
```

AppArmor will be configured and re-enabled later in this deployment procedure.

Configure Character Encoding

When using MariaDB Enterprise ColumnStore, it is recommended to set the system's locale to UTF-8.

1. On RHEL 8, install additional dependencies:

```
$ sudo yum install glibc-locale-source glibc-langpack-en
```

2. Set the system's locale to en_US.UTF-8 by executing localedef:

```
$ sudo localedef -i en_US -f UTF-8 en_US.UTF-8
```

Create an S3 Bucket

With the HTAP topology, it is important to create the S3 bucket before you start ColumnStore.

If you already have an S3 bucket, confirm that the bucket is empty.

S3 bucket configuration will be performed later in this procedure.

Next Step

Navigation in the procedure "Deploy HTAP Topology".

This page was step 1 of 4.

Next: Step 2: Install MariaDB Enterprise Server.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 2: Install MariaDB Enterprise Server

Overview

This page details step 2 of the 4-step procedure "Deploy HTAP Topology".

This step installs MariaDB Enterprise Server MariaDB Enterprise ColumnStore 23.10, and dependencies.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Retrieve Download Token

MariaDB Corporation provides package repositories for CentOS / RHEL (YUM) and Debian / Ubuntu (APT). A download token is required to access the MariaDB Enterprise Repository.

Customer Download Tokens are customer-specific and are available through the MariaDB Customer Portal.

To retrieve the token for your account:

1. Navigate to https://customers.mariadb.com/downloads/token/
2. Log in.
3. Copy the Customer Download Token.

Substitute your token for `CUSTOMER_DOWNLOAD_TOKEN` when configuring the package repositories.

Set Up Repository

1. On each Enterprise ColumnStore node, install the prerequisites for downloading the software from the Web.
   Install on CentOS / RHEL (YUM):

```
$ sudo yum install curl
```

Install on Debian / Ubuntu (APT):

```
$ sudo apt install curl apt-transport-https
```

2. On each Enterprise ColumnStore node, configure package repositories and specify Enterprise Server:

```
$ curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
```

```
$ echo "${checksum}  mariadb_es_repo_setup" \
       | sha256sum -c -
```

```
$ chmod +x mariadb_es_repo_setup
```

```
$ sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
      --skip-maxscale \
      --skip-tools \
      --mariadb-server-version="11.4"
```

Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.

Install Enterprise Server and Enterprise ColumnStore

1. **On each Enterprise ColumnStore node**, install additional dependencies:
   Install on CentOS / RHEL (YUM)

```
$ sudo yum install epel-release

$ sudo yum install jemalloc
```

Install of Debian 10 and Ubuntu 20.04 (APT):

```
$ sudo apt install libjemalloc2
```

Install on Debian 9 and Ubuntu 18.04 (APT):

```
$ sudo apt install libjemalloc1
```

2. **On the Enterprise ColumnStore node**, install MariaDB Enterprise Server and MariaDB Enterprise ColumnStore:

Install on CentOS / RHEL (YUM):

```
$ sudo yum install MariaDB-server \
      MariaDB-backup \
      MariaDB-shared \
      MariaDB-client \
      MariaDB-columnstore-engine
```

Install on Debian / Ubuntu (APT):

```
$ sudo apt install mariadb-server \
      mariadb-backup \
      libmariadb3 \
      mariadb-client \
      mariadb-plugin-columnstore
```

Next Step

Navigation in the procedure “Deploy HTAP Topology”.

This page was step 2 of 4.

Next: Step 3: Start and Configure MariaDB Enterprise Server.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 3: Start and Configure MariaDB Enterprise Server

Overview

This page details step 3 of the 4-step procedure “Deploy HTAP Topology”.

This step starts and configures MariaDB Enterprise Server and MariaDB Enterprise ColumnStore 23.10.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Stop the Enterprise ColumnStore Services

The installation process might have started some of the ColumnStore services. The services should be stopped prior to making configuration changes.

1. On each Enterprise ColumnStore node, stop the MariaDB Enterprise Server service:

```
$ sudo systemctl stop mariadb
```

2. On each Enterprise ColumnStore node, stop the MariaDB Enterprise ColumnStore service:

```
$ sudo systemctl stop mariadb-columnstore
```

3. On each Enterprise ColumnStore node, stop the CMAPI service:

```
$ sudo systemctl stop mariadb-columnstore-cmapi
```

Configure Enterprise ColumnStore

On each Enterprise ColumnStore node, configure Enterprise Server.

Connector	MariaDB Connector/R2DBC
binlog_do_db	Set this to the name of the database to replicate from InnoDB to ColumnStore.
binlog_format	Set this to STATEMENT for HTAP.
character_set_server	Set this system variable to utf8
collation_server	Set this system variable to utf8_general_ci
loose-columnstore_use_import_for_batchinsert	Set this system variable to ALWAYS to always use cpimport for LOAD DATA INFILE and INSERT…SELECT statements.
gtid_strict_mode	Set this system variable to ON.
log_bin	Set this option to the file you want to use for the Binary Log. Setting this option enables binary logging.
log_slave_updates	Set this system variable to ON.
replicate_rewrite_db	Set this option to the file you want to use for the Relay Logs. Setting this option enables relay logging.
replicate_wild_do_table	Set this option to the file you want to use to index Relay Log filenames.
server_id	Sets the numeric Server ID for this MariaDB Enterprise Server. The value set on this option must be unique to each node.

Example Configuration

```
[mariadb]
log_error                              = mariadbd.err
character_set_server                   = utf8
collation_server                       = utf8_general_ci

# Replication Configuration (HTAP Server)
server_id                      = 1
log_bin                        = mariadb-bin
binlog_format                  = STATEMENT
log_slave_updates              = OFF
loose-columnstore_replication_slave = ON

# HTAP filtering rules

# Transactions replicate from same server
replicate_same_server_id = ON

# Only write queries that touch 'innodb_db' to the binary log
binlog_do_db = innodb_db

# Rewrite innodb_db to columnstore_db prior to applying transaction
replicate_rewrite_db = innodb_db->columnstore_db

# Only replicate tables that begin with "htap"
replicate_wild_do_table = columnstore_db.htap%
```

> **Warning:**
>
> The `loose-` prefix is required for ColumnStore system variables in the configuration file. Without it, MariaDB Server will fail to start if the ColumnStore plugin is not installed or has been removed.

Configure the S3 Storage Manager

Configure Enterprise ColumnStore S3 Storage Manager to use S3-compatible storage by editing the `/etc/columnstore/storagemanager.cnf` configuration file:

```
[ObjectStorage]
…
service = S3
…
[S3]
bucket                = your_columnstore_bucket_name
endpoint              = your_s3_endpoint
aws_access_key_id     = your_s3_access_key_id
aws_secret_access_key = your_s3_secret_key
# iam_role_name       = your_iam_role
# sts_region          = your_sts_region
# sts_endpoint        = your_sts_endpoint
# ec2_iam_mode        = enabled

[Cache]
cache_size = your_local_cache_size
path       = your_local_cache_path
```

The S3-compatible object storage options are configured under [S3]:

- The bucket option must be set to the name of the bucket that you created in “Create an S3 Bucket”.
- The endpoint option must be set to the endpoint for the S3-compatible object storage.
- The `aws_access_key_id and aws_secret_access_key` options must be set to the access key ID and secret access key for the S3-compatible object storage.
- To use a specific IAM role, you must uncomment and set `iam_role_name, sts_region, and sts_endpoint`.
- To use the IAM role assigned to an EC2 instance, you must uncomment `ec2_iam_mode=enabled`.

The local cache options are configured under [Cache]:

- The `cache_size` option is set to 2 GB by default.
- The path option is set to `/var/lib/columnstore/storagemanager/cache` by default.
- Ensure that the specified path has sufficient storage space for the specified cache size.

Start the Enterprise ColumnStore Services

Start and enable the MariaDB Enterprise Server service, so that it starts automatically upon reboot:

```
$ sudo systemctl start mariadb

$ sudo systemctl enable mariadb
```

Start and enable the MariaDB Enterprise ColumnStore service, so that it starts automatically upon reboot:

```
$ sudo systemctl start mariadb-columnstore

$ sudo systemctl enable mariadb-columnstore
```

For additional information, see “Starting and Stopping MariaDB”.

Create User Accounts

The HTAP topology requires several user accounts.

Create the Utility User

Enterprise ColumnStore requires a mandatory utility user account. By default, it connects to the server using the root user with no password. MariaDB Enterprise Server 10.6 will reject this login attempt by default, so you will need to configure Enterprise ColumnStore to use a different user account and password and create this user account on Enterprise Server.

1. On the Enterprise ColumnStore node, create the user account with the CREATE USER statement:

```
CREATE USER 'util_user'@'127.0.0.1'
IDENTIFIED BY 'util_user_passwd';
```

2. On the Enterprise ColumnStore node, grant the user account SELECT privileges on all databases with the GRANT statement:

```
GRANT SELECT, PROCESS ON *.*
TO 'util_user'@'127.0.0.1';
```

3. Configure Enterprise ColumnStore to use the utility user:

```
$ sudo mcsSetConfig CrossEngineSupport Host 127.0.0.1

$ sudo mcsSetConfig CrossEngineSupport Port 3306

$ sudo mcsSetConfig CrossEngineSupport User util_user
```

4. Set the password:

```
$ sudo mcsSetConfig CrossEngineSupport Password util_user_passwd
```

For details about how to encrypt the password, see "Credentials Management for MariaDB Enterprise ColumnStore".

Passwords should meet your organization's password policies. If your MariaDB Enterprise Server instance has a password validation plugin installed, then the password should also meet the configured requirements.

Create the Replication User

Enterprise HTAP uses MariaDB Replication to replicate writes between InnoDB tables and ColumnStore tables.

Create a replication user and grant it the required privileges:

1. Use the CREATE USER statement to create replication users for each replica server:

```
CREATE USER 'repl'@'localhost' IDENTIFIED BY 'passwd';
```

2. Grant the user account several global privileges with the GRANT statement.

```
GRANT REPLICA MONITOR,
   REPLICATION REPLICA
ON *.* TO 'repl'@'localhost';
```

Configure MariaDB Replication

1. Set the GTID position by setting the gtid_slave_pos system variable.
   If this is a new deployment, then it would be set to the empty string:

```
SET GLOBAL gtid_slave_pos='';
```

2. Use the CHANGE MASTER TO statement to configure the server to replicate from itself starting from this position:

```
CHANGE MASTER TO
   MASTER_HOST='localhost',
   MASTER_USER='htap_replication',
   MASTER_PASSWORD='passwd',
   MASTER_USE_GTID=slave_pos;
```

3. Start replication using the START REPLICA statement:

```
START REPLICA;
```

4. Confirm that replication is working using the SHOW REPLICA STATUS statement:

```
SHOW REPLICA STATUS;
```

Configure Linux Security Modules (LSM)

The specific steps to configure the security module depend on the operating system.

Configure SELinux (CentOS, RHEL)

Configure SELinux for Enterprise ColumnStore:

1. To configure SELinux, you have to install the packages required for audit2allow.
   On CentOS 7 and RHEL 7, install the following:

```
$ sudo yum install policycoreutils policycoreutils-python
```

On RHEL 8, install the following:

```
$ sudo yum install policycoreutils python3-policycoreutils policycoreutils-python-utils
```

2. Allow the system to run under load for a while to generate SELinux audit events.
3. After the system has taken some load, generate an SELinux policy from the audit events using audit2allow:

```
$ sudo grep mysqld /var/log/audit/audit.log | audit2allow -M mariadb_local
```

If no audit events were found, this will print the following:

```
$ sudo grep mysqld /var/log/audit/audit.log | audit2allow -M mariadb_local

Nothing to do
```

4. If audit events were found, the new SELinux policy can be loaded using semodule:

```
$ sudo semodule -i mariadb_local.pp
```

5. Set SELinux to enforcing mode by setting SELINUX=enforcing in /etc/selinux/config.

For example, the file will usually look like this after the change:

```
# This file controls the state of SELinux on the system.
# SELINUX= can take one of these three values:
#     enforcing - SELinux security policy is enforced.
#     permissive - SELinux prints warnings instead of enforcing.
#     disabled - No SELinux policy is loaded.
SELINUX=enforcing
# SELINUXTYPE= can take one of three values:
#     targeted - Targeted processes are protected,
#     minimum - Modification of targeted policy. Only selected processes are protected.
#     mls - Multi Level Security protection.
SELINUXTYPE=targeted
```

6. Set SELinux to enforcing mode:

```
$ sudo setenforce enforcing
```

Configure AppArmor (Ubuntu)

For information on how to create a profile, see How to create an AppArmor Profile on ubuntu.com.

Next Step

Navigation in the procedure “Deploy HTAP Topology”.

This page was step 3 of 4.

Next: Step 4: Test MariaDB Enterprise Server.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 4: Test MariaDB Enterprise Server

Overview

This page details step 4 of the 4-step procedure “Deploy HTAP Topology”.

This step tests Enterprise ColumnStore.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Test S3 Connection

MariaDB Enterprise ColumnStore includes a `testS3Connection` command to test the S3 configuration, permissions, and connectivity.

Test the S3 configuration by executing the following:

```
$ sudo testS3Connection
```

```
StorageManager[26887]: Using the config file found at /etc/columnstore/storagemanager.cnf
StorageManager[26887]: S3Storage: S3 connectivity & permissions are OK
S3 Storage Manager Configuration OK
```

If the testS3Connection command does not return OK, investigate the S3 configuration.

Test Enterprise Server Service

Use Systemd to test whether the MariaDB Enterprise Server service is running.

Check if the MariaDB Enterprise Server service is running by executing the following:

```
$ systemctl status mariadb
```

If the service is not running, start the service by executing the following:

```
$ sudo systemctl start mariadb
```

Test Local Client Connections

Use MariaDB Client to test the local connection to the Enterprise Server node:

```
$ sudo mariadb
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 38
Server version: MariaDB-Enterprise MariaDB Enterprise Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]>
```

The sudo command is used here to connect to the Enterprise Server node using the root@localhost user account, which authenticates using the unix_socket authentication plugin. Other user accounts can be used by specifying the –user and –password command-line options.

Test ColumnStore Storage Engine Plugin

Query the information_schema.PLUGINS table to confirm that the ColumnStore storage engine is loaded.

Execute the following query:

```
SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM information_schema.PLUGINS
WHERE PLUGIN_LIBRARY LIKE 'ha_columnstore%';

+---------------------+---------------+
| PLUGIN_NAME         | PLUGIN_STATUS |
+---------------------+---------------+
| Columnstore         | ACTIVE        |
| COLUMNSTORE_COLUMNS | ACTIVE        |
| COLUMNSTORE_TABLES  | ACTIVE        |
| COLUMNSTORE_FILES   | ACTIVE        |
| COLUMNSTORE_EXTENTS | ACTIVE        |
+---------------------+---------------+
```

The `PLUGIN_STATUS` column for each ColumnStore-related plugin should contain ACTIVE.

Test Replication Status

Use the SHOW REPLICA STATUS statement to check the status of MariaDB Replication:

```
SHOW REPLICA STATUS\G

*************************** 1. row ***************************
               Slave_IO_State: Waiting for master to send event
                  Master_Host: localhost
                  Master_User: repl
                  Master_Port: 3306
                Connect_Retry: 60
              Master_Log_File: mariadb-bin.000002
          Read_Master_Log_Pos: 695
               Relay_Log_File: mysqld-relay-bin.000002
                Relay_Log_Pos: 996
        Relay_Master_Log_File: mariadb-bin.000002
             Slave_IO_Running: Yes
            Slave_SQL_Running: Yes
              Replicate_Do_DB:
          Replicate_Ignore_DB:
           Replicate_Do_Table:
       Replicate_Ignore_Table:
      Replicate_Wild_Do_Table: columnstore_db.htap%
  Replicate_Wild_Ignore_Table:
                   Last_Errno: 0
                   Last_Error:
                 Skip_Counter: 0
          Exec_Master_Log_Pos: 695
              Relay_Log_Space: 1306
              Until_Condition: None
               Until_Log_File:
                Until_Log_Pos: 0
           Master_SSL_Allowed: No
           Master_SSL_CA_File:
           Master_SSL_CA_Path:
              Master_SSL_Cert:
            Master_SSL_Cipher:
               Master_SSL_Key:
        Seconds_Behind_Master: 0
Master_SSL_Verify_Server_Cert: No
                Last_IO_Errno: 0
                Last_IO_Error:
               Last_SQL_Errno: 0
               Last_SQL_Error:
  Replicate_Ignore_Server_Ids:
             Master_Server_Id: 1
               Master_SSL_Crl:
           Master_SSL_Crlpath:
                   Using_Gtid: Slave_Pos
                  Gtid_IO_Pos: 0-1-7
      Replicate_Do_Domain_Ids:
  Replicate_Ignore_Domain_Ids:
               Parallel_Mode: optimistic
                   SQL_Delay: 0
         SQL_Remaining_Delay: NULL
      Slave_SQL_Running_State: Slave has read all relay log; waiting for more updates
             Slave_DDL_Groups: 1
Slave_Non_Transactional_Groups: 0
    Slave_Transactional_Groups: 1
```

Test ColumnStore Table Creation

1. Create a test database, if it does not exist:

```
CREATE DATABASE IF NOT EXISTS test;
```

2. Create a ColumnStore table:

```
CREATE TABLE IF NOT EXISTS test.contacts (
   first_name VARCHAR(50),
   last_name VARCHAR(50),
   email VARCHAR(100)
) ENGINE=ColumnStore;
```

3. Add sample data into the table:

```
INSERT INTO test.contacts (first_name, last_name, email)
   VALUES
   ("Kai", "Devi", "kai.devi@example.com"),
   ("Lee", "Wang", "lee.wang@example.com");
```

4. Read data from table:

```
SELECT * FROM test.contacts;

+------------+-----------+----------------------+
| first_name | last_name | email                |
+------------+-----------+----------------------+
| Kai        | Devi      | kai.devi@example.com |
| Lee        | Wang      | lee.wang@example.com |
+------------+-----------+----------------------+
```

Test Cross Engine Join

1. Create an InnoDB table:

```
CREATE TABLE test.addresses (
   email VARCHAR(100),
   street_address VARCHAR(255),
   city VARCHAR(100),
   state_code VARCHAR(2)
) ENGINE = InnoDB;
```

2. Add data to the table:

```
INSERT INTO test.addresses (email, street_address, city, state_code)
   VALUES
   ("kai.devi@example.com", "1660 Amphibious Blvd.", "Redwood City", "CA"),
   ("lee.wang@example.com", "32620 Little Blvd", "Redwood City", "CA");
```

3. Perform a cross-engine join:

```
SELECT name AS "Name", addr AS "Address"
FROM (SELECT CONCAT(first_name, " ", last_name) AS name,
   email FROM test.contacts) AS contacts
INNER JOIN (SELECT CONCAT(street_address, ", ", city, ", ", state_code) AS addr,
   email FROM test.addresses) AS addr
WHERE  contacts.email = addr.email;

+----------+----------------------------------------+
| Name     | Address                                |
+----------+----------------------------------------+
| Kai Devi | 1660 Amphibious Blvd., Redwood City, CA |
| Lee Wang | 32620 Little Blvd, Redwood City, CA     |
+----------+----------------------------------------+
```

Test HTAP Replication

1. Connect to the server using MariaDB Client using the root@localhost user account:

```
$ sudo mariadb
```

2. Create the databases for the InnoDB and ColumnStore tables using the CREATE DATABASE statement:

```
CREATE DATABASE columnstore_db;

CREATE DATABASE innodb_db;
```

3. Create the InnoDB versions of the HTAP tables using the CREATE TABLE statement:

```
USE innodb_db;

CREATE TABLE htap_test1 (
   id INT
) ENGINE = InnoDB;

CREATE TABLE htap_test2 (
   id INT
) ENGINE = InnoDB;
```

4. Confirm that the tables were replicated using the SHOW TABLES statement:

```
SHOW TABLES FROM columnstore_db;

+--------------------------+
| Tables_in_columnstore_db |
+--------------------------+
| htap_test1               |
| htap_test2               |
+--------------------------+
```

5. The replication initially creates empty InnoDB tables, which need to be transformed into ColumnStore tables and which need to be populated with the initial copy of the data:

```
DROP TABLE IF EXISTS columnstore_db.htap_test1;

CREATE TABLE columnstore_db.htap_test1
ENGINE=COLUMNSTORE
SELECT * FROM innodb_db.htap_test1;

DROP TABLE IF EXISTS columnstore_db.htap_test2;

CREATE TABLE columnstore_db.htap_test2
ENGINE=COLUMNSTORE
SELECT * FROM innodb_db.htap_test2;
```

6. Insert data into the InnoDB versions of the HTAP tables using the INSERT statement:

```
USE innodb_db;

INSERT INTO htap_test1
VALUES (100);

INSERT INTO htap_test2
VALUES (200);
```

7. Confirm that the data was replicated using the SELECT statement:

```
SELECT * FROM columnstore_db.htap_test1;

+------+
| id   |
+------+
|  100 |
+------+

SELECT * FROM columnstore_db.htap_test2;

+------+
| id   |
+------+
|  200 |
+------+
```

8. Create an InnoDB table that will not be replicated:

```
USE innodb_db;
CREATE TABLE transactional_test1 (
   id INT
) ENGINE = InnoDB;
```

9. Confirm that the table was not replicated:

```
SHOW TABLES FROM columnstore_db LIKE 'transactional_%';

Empty set (0.02 sec)
```

10. Create a ColumnStore table that will not be replicated:

```
USE columnstore_db;
CREATE TABLE analytical_test1 (
   id INT
) ENGINE = ColumnStore;
```

11. Confirm that the table was not replicated:

```
SHOW TABLES FROM innodb_db LIKE 'analytical_%';

Empty set (0.02 sec)
```

Next Step

Navigation in the procedure “Deploy HTAP Topology”.
This page was step 4 of 4.

This procedure is complete.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 1: Install MariaDB Enterprise Server

Overview

This page details step 1 of the 7-step procedure “Deploy Primary/Replica Topology”.

This step installs MariaDB Enterprise Server

The Primary/Replica topology requires 3 or more MariaDB Enterprise Server nodes for High Availability (HA). Nodes must meet requirements.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Retrieve Download Token

MariaDB Corporation provides package repositories for CentOS / RHEL (YUM) and Debian / Ubuntu (APT). A download token is required to access the MariaDB Enterprise Repository.

Customer Download Tokens are customer-specific and are available through the MariaDB Customer Portal.

To retrieve the token for your account:

1. Navigate to https://customers.mariadb.com/downloads/token/
2. Log in.
3. Copy the Customer Download Token.

Substitute your token for `CUSTOMER_DOWNLOAD_TOKEN` when configuring the package repositories.

Set Up Repository

1. On each Enterprise ColumnStore node, install the prerequisites for downloading the software from the Web. Install on CentOS / RHEL (YUM):

```
$ sudo yum install curl
```

Install on Debian / Ubuntu (APT):

```
$ sudo apt install curl apt-transport-https
```

2. On each Enterprise ColumnStore node, configure package repositories and specify Enterprise Server:

```
$ curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
```

```
$ echo "${checksum}  mariadb_es_repo_setup" \
       | sha256sum -c -
```

```
$ chmod +x mariadb_es_repo_setup
```

```
$ sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
      --skip-maxscale \
      --skip-tools \
      --mariadb-server-version="11.4"
```

Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.

Install Enterprise Server

1. On each Enterprise Cluster node, install MariaDB Enterprise Server and MariaDB Enterprise Backup.

Install via CentOS / RHEL (YUM):

```
$ sudo yum install MariaDB-server MariaDB-backup
```

Install via Debian / Ubuntu (APT):

```
$ sudo apt update

$ sudo apt install mariadb-server mariadb-backup
```

Install via SLES (ZYpp):

```
$ sudo zypper install MariaDB-server MariaDB-backup
```

Next Step

Navigation in the procedure “Deploy Primary/Replica Topology”:

This page was step 1 of 7.

Next: Step 2: Start and Configure MariaDB Enterprise Server on Primary Server

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 2: Start and Configure MariaDB Enterprise Server on Primary Server

Overview

This page details step 2 of the 7-step procedure “Deploy Primary/Replica Topology”.

This step starts and configures a MariaDB Enterprise Server to operate as a primary server in MariaDB Replication.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Stop the Enterprise Server Service

The installation process might have started the Enterprise Server service. The service should be stopped prior to making configuration changes.

Stop the MariaDB Enterprise Server service:

```
$ sudo systemctl stop mariadb
```

Configure Enterprise Server

Enterprise Server nodes require that you set the following system variables and options:

System Variable/Option	Description
bind_address	The network socket Enterprise Server listens on for incoming TCP/IP client connections. On Debian or Ubuntu, this system variable must be set to override the 127.0.0.1 default configuration.
log_bin	Set this option to the file you want to use for the Binary Log. Setting this option enables binary logging.
server_id	Sets the numeric Server ID for this MariaDB Enterprise Server. The value set on this option must be unique to each node.

MariaDB Enterprise Server also supports group commit.

Group Commit

Group commit can help performance by reducing I/O.

If you would like to configure parallel replication on replica servers, then you must also configure group commit on the primary server.

System Variable	Description
binlog_commit_wait_count	Sets the number of transactions that the server commits as a group to the binary log.
binlog_commit_wait_usec	Sets the number of microseconds that the server waits for transactions to group commit before it commits the current group.

Example Configuration

On each Enterprise Server node, edit a configuration file and set these system variables and options:

```
[mariadb]
bind_address = 0.0.0.0
log_bin      = mariadb-bin.log
server_id    = 1
```

Set the server_id option to a value that is unique for each Enterprise Server node.

Start Primary Server

Start MariaDB Enterprise Server. If the Enterprise Server process is already running, restart it to apply the changes from the configuration file.

```
$ systemctl start mariadb
```

For additional information, see "Starting and Stopping MariaDB".

Create User Accounts

The Primary/Replica topology requires several user accounts. Each user account should be created on the primary server, so that it is replicated to the replica servers.

Create the Replication User

Primary/Replica uses MariaDB Replication to replicate writes between the primary and replica servers. As MaxScale can promote a replica server to become a new primary in the event of node failure, all nodes must have a replication user.

The action is performed on the primary server.

Create the replication user and grant it the required privileges:

1. Use the CREATE USER statement to create replication user.

```
CREATE USER 'repl'@'192.0.2.%' IDENTIFIED BY 'repl_passwd';
```

Replace the referenced IP address with the relevant address for your environment.

Ensure that the user account can connect to the primary server from each replica.

2. Grant the user account the required privileges with the GRANT statement.

The following privileges are required:

```
GRANT REPLICATION SLAVE,
   REPLICATION CLIENT
ON *.* TO repl@'%';
```

Use this username and password for the `MASTER_USER and MASTER_PASSWORD` in the CHANGE MASTER TO statement when configuring replica servers in Step 3.

Create MaxScale User

Primary/Replica uses MariaDB MaxScale 25.01 to load balance between the nodes. MaxScale requires a database user to connect to the primary server when routing queries and to promote replicas in the event that the primary server fails.

This action is performed on the primary server.

1. Use the CREATE USER statement to create the MaxScale user:

```
CREATE USER 'mxs'@'192.0.2.%'
IDENTIFIED BY 'mxs_passwd';
```

Replace the referenced IP address with the relevant address for your environment.

Ensure that the user account can connect from the IP address of the MaxScale instance.

2. Use the GRANT statement to grant the privileges required by the router:

```
GRANT SHOW DATABASES ON *.* TO 'mxs'@'192.0.2.%';

GRANT SELECT ON mysql.columns_priv TO 'mxs'@'192.0.2.%';

GRANT SELECT ON mysql.db TO 'mxs'@'192.0.2.%';

GRANT SELECT ON mysql.procs_priv TO 'mxs'@'192.0.2.%';

GRANT SELECT ON mysql.proxies_priv TO 'mxs'@'192.0.2.%';

GRANT SELECT ON mysql.roles_mapping TO 'mxs'@'192.0.2.%';

GRANT SELECT ON mysql.tables_priv TO 'mxs'@'192.0.2.%';

GRANT SELECT ON mysql.user TO 'mxs'@'192.0.2.%';
```

3. Use the GRANT statement to grant privileges required by the MariaDB Monitor.

The following privileges are required:

```
GRANT SUPER,
   REPLICATION CLIENT,
   RELOAD,
   PROCESS,
   SHOW DATABASES,
   EVENT
ON *.* TO 'mxs'@'192.0.2.%';
```

Next Step

Navigation in the procedure “Deploy Primary/Replica Topology”:

This page was step 2 of 7.

Next: Step 3: Start and Configure MariaDB Enterprise Server on Replica Servers

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 3: Start and Configure MariaDB Enterprise Server on Replica Servers

Overview

This page details step 3 of the 7-step procedure “Deploy Primary/Replica Topology”.

This page starts and configures a MariaDB Enterprise Server 11.4 to operate as a replica server in MariaDB Replication.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Stop the Enterprise Server Service

The installation process might have started the Enterprise Server service. The service should be stopped prior to making configuration changes.

On each Enterprise Server node, stop the MariaDB Enterprise Server service:

```
$ sudo systemctl stop mariadb
```

Configure Enterprise Server

Enterprise Server nodes require that you set the following system variables and options:

System Variable/Option	Description
bind_address	The network socket Enterprise Server listens on for incoming TCP/IP client connections. On Debian or Ubuntu, this system variable must be set to override the 127.0.0.1 default configuration.
log_bin	Enables binary logging and sets the name of the binlog file.
server_id	Unique numeric identifier for each Enterprise Server node.

MariaDB Enterprise Server also supports group commit.

Parallel Replication

Writes to the primary server that are group committed or logged with a Global Transaction ID in different replication domains can be applied on the replica server using parallel threads to improve performance.

System Variable/Option	Description
slave_parallel_threads	Sets the number of threads the replica server uses to apply replication events in parallel. Use a non-zero value to enable Parallel Replication.
slave_parallel_mode	Sets how the replica server applies replicated transactions.

Example Configuration

On each Enterprise Server node, edit a configuration file and set these system variables and options:

```
[mariadb]
bind_address = 0.0.0.0
log_bin      = mariadb-bin.log
server_id    = 1
```

Set the server_id option to a value that is unique for each Enterprise Server node.

Initialize Replica Database

When deploying a new replica server to an existing system, back up the primary server and restore it on the replica server to initialize the database.

Back up the Primary Server

Use MariaDB Backup to back up the primary server.

1. On the primary server, take a full backup:

```
$ sudo mariadb-backup --backup \
      --user=mariadb-backup_user \
      --password=mariadb-backup_passwd \
      --target-dir=/data/backup/replica_backup
```

Confirm successful completion of the backup operation.

2. On the primary server, prepare the backup:

```
$ sudo mariadb-backup --prepare \
      --target-dir=/data/backup/replica_backup
```

Confirm successful completion of the prepare operation.

Restore the Backup to the Replica Server

1. **On the primary server**, copy the backup directory to each replica server:

```
$ sudo rsync -av /data/backup/replica_backup 192.0.2.11:/data/backup/
```

2. **On the replica server**, move the default datadir to another location:

```
$ sudo mv /var/lib/mysql /var/lib/mysql_backup
```

3. **On the replica server**, use MariaDB Backup to restore the backup to the datadir:

```
$ sudo mariadb-backup --copy-back \
   --target-dir=/data/backup/replica_backup
```

4. **On the replica server**, set the file permissions for the datadir:

```
$ sudo chown -R mysql:mysql /var/lib/mysql
```

Start Replica Server

Start MariaDB Enterprise Server. If the Enterprise Server process is already running, restart it to apply the changes from the configuration file.

```
$ systemctl start mariadb
```

For additional information, see “Starting and Stopping MariaDB”.

Set the Global Transaction ID Position

If the replica server was restored from a backup of the primary, set the GTID position.

1. Get the GTID position that corresponds to the restored backup. This can be found in the xtrabackup_binlong_info file.

```
$ cat xtrabackup_binlog_info
mariadb-bin.000096 568 0-1-2001,1-2-5139
```

The GTID position from the above output is `0-1-2001,1-2-5139`.

2. Connect to the replica server:

```
$ sudo mariadb
```

Set the gtid_slave_pos system variable to the GTID position:

```
SET GLOBAL gtid_slave_pos='0-1-2001,1-2-5139';
```

Start Replication

1. Execute the CHANGE MASTER TO statement to configure the replica server to connect to the primary server at this position:

```
CHANGE MASTER TO
   MASTER_USER = "repl",
   MASTER_HOST = "192.0.2.10",
   MASTER_PASSWORD = "repl_passwd",
   MASTER_USE_GTID = slave_pos;
```

The above statement configures the replica server to connect to a primary server located at 192.0.2.10 using the repl user account. This account must first be configured on the primary server.

2. Use the START REPLICA statement to start replication:

```
START REPLICA;
```

3. Use SHOW REPLICA STATUS statement to confirm replication is running:

```
SHOW REPLICA STATUS\G

*************************** 1. row ***************************
               Slave_IO_State: Waiting for master to send event
                  Master_Host: 192.0.2.10
                  Master_User: repl
                  Master_Port: 3306
                Connect_Retry: 60
              Master_Log_File: mariadb-bin.000001
          Read_Master_Log_Pos: 645
               Relay_Log_File: li282-189-relay-bin.000002
                Relay_Log_Pos: 946
        Relay_Master_Log_File: mariadb-bin.000001
             Slave_IO_Running: Yes
            Slave_SQL_Running: Yes
              Replicate_Do_DB:
          Replicate_Ignore_DB:
           Replicate_Do_Table:
       Replicate_Ignore_Table:

           Master_SSL_Crlpath:
                   Using_Gtid: Slave_Pos
                  Gtid_IO_Pos: 0-1-2
      Replicate_Do_Domain_Ids:
  Replicate_Ignore_Domain_Ids:
               Parallel_Mode: optimistic
                   SQL_Delay: 0
         SQL_Remaining_Delay: NULL
     Slave_SQL_Running_State: Slave has read all relay log; waiting for more updates
            Slave_DDL_Groups: 2
Slave_Non_Transactional_Groups: 0
    Slave_Transactional_Groups: 0
```

Next Step

Navigation in the procedure “Deploy Primary/Replica Topology”:

This page was step 3 of 7.

Next: Step 4: Test MariaDB Enterprise Server

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 4: Test MariaDB Enterprise Server

Overview

This page details step 4 of the 7-step procedure "Deploy Primary/Replica Topology".

This step tests MariaDB Enterprise Server

Several actions require connection to MariaDB Enterprise Server. A command-line client (mariadb) was included with your ES installation. These instructions describe connection via Unix domain socket. Alternatively, a different client and connection method could be used.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Test Enterprise Server Service

Use Systemd to test whether the MariaDB Enterprise Server service is running.

This action is performed **on each Enterprise Server node**.

Check if the MariaDB Enterprise Server service is running by executing the following:

```
$ systemctl status mariadb
```

If the service is not running on any node, start the service by executing the following on that node:

```
$ sudo systemctl start mariadb
```

Test Local Client Connections

Use mariadb Client to test the local connection to the Enterprise Server node.

This action is performed **on each Enterprise Server node**:

```
$ sudo mariadb
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 38
Server version: 11.4.5-3-MariaDB-Enterprise MariaDB Enterprise Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]>
```

The sudo command is used here to connect to the Enterprise Server node using the root@localhost user account, which authenticates using the unix_socket authentication plugin. Other user accounts can be used by specifying the `--user` and `--password` command-line options.

Test Replica Status

Use SHOW REPLICA STATUS to check that replication is running properly on the replica servers.

This action is performed **on each replica server**.

Execute the following:

```
SHOW REPLICA STATUS\G

*************************** 1. row ***************************
               Slave_IO_State: Waiting for master to send event
                  Master_Host: 192.0.2.1
                  Master_User: repl
                  Master_Port: 3306
                Connect_Retry: 60
              Master_Log_File: mariadb-bin.000001
          Read_Master_Log_Pos: 645
               Relay_Log_File: li282-189-relay-bin.000002
                Relay_Log_Pos: 946
        Relay_Master_Log_File: mariadb-bin.000001
             Slave_IO_Running: Yes
            Slave_SQL_Running: Yes
              Replicate_Do_DB:
          Replicate_Ignore_DB:
           Replicate_Do_Table:
       Replicate_Ignore_Table:
      Replicate_Wild_Do_Table:
  Replicate_Wild_Ignore_Table:
                   Last_Errno: 0
                   Last_Error:
                 Skip_Counter: 0
          Exec_Master_Log_Pos: 645
              Relay_Log_Space: 1259
              Until_Condition: None
               Until_Log_File:
                Until_Log_Pos: 0
           Master_SSL_Allowed: No
           Master_SSL_CA_File:
           Master_SSL_CA_Path:
              Master_SSL_Cert:
            Master_SSL_Cipher:
               Master_SSL_Key:
        Seconds_Behind_Master: 0
Master_SSL_Verify_Server_Cert: No
                Last_IO_Errno: 0
                Last_IO_Error:
               Last_SQL_Errno: 0
               Last_SQL_Error:
  Replicate_Ignore_Server_Ids:
             Master_Server_Id: 1
               Master_SSL_Crl:
           Master_SSL_Crlpath:
                   Using_Gtid: Slave_Pos
                  Gtid_IO_Pos: 0-1-2
      Replicate_Do_Domain_Ids:
  Replicate_Ignore_Domain_Ids:
               Parallel_Mode: optimistic
                   SQL_Delay: 0
         SQL_Remaining_Delay: NULL
     Slave_SQL_Running_State: Slave has read all relay log; waiting for more updates
            Slave_DDL_Groups: 2
Slave_Non_Transactional_Groups: 0
    Slave_Transactional_Groups: 0
```

If `Slave_IO_Running` column is not `Yes` on any replica server, then check:

- The network connectivity between the replica server and the primary server
- The `Last_IO_Error` column for details on any errors

If `Slave_SQL_Running` column is not Yes on any replica server, then check:

- The GTID position in gtid_slave_pos
- The `Last_SQL_Error` column for details on any errors

If both columns are not `Yes` on any replica server, then check:

- The replication configuration on the replica server.

If you need to make any corrections, the slave threads can be restarted with START REPLICA.

Test DDL

Use mariadb Client to test DDL.

1. **On the primary server**, use the mariadb Client to connect to the node:

```
$ sudo mariadb
```

2. Create a test database and table:

```
CREATE DATABASE IF NOT EXISTS test;

CREATE TABLE test.contacts (
   id INT PRIMARY KEY AUTO_INCREMENT,
   first_name VARCHAR(50),
   last_name VARCHAR(50),
   email VARCHAR(100)
);
```

3. **On each replica server**, use the mariadb Client to connect to the node:

```
$ sudo mariadb
```

4. Confirm that the database and table exist:

```
SHOW CREATE TABLE test.contacts\G;
```

If the database or table do not exist on any node, then check the replication status on the node.

Test DML

Use mariadb Client to test DML.

1. **On the primary server**, use the MariaDB Client to connect to the node:

```
$ sudo mariadb
```

2. Insert sample data into the table created in the DDL test:

```
INSERT INTO test.contacts (first_name, last_name, email)
   VALUES
   ("Kai", "Devi", "kai.devi@example.com"),
   ("Lee", "Wang", "lee.wang@example.com");
```

3. **On each replica server**, use the mariadb Client to connect to the node:

```
$ sudo mariadb
```

4. Execute a SELECT query to retrieve the data:

```
SELECT * FROM test.contacts;

+----+------------+-----------+----------------------+
| id | first_name | last_name | email                |
+----+------------+-----------+----------------------+
| 1  | Kai        | Devi      | kai.devi@example.com |
| 2  | Lee        | Wang      | lee.wang@example.com |
+----+------------+-----------+----------------------+
```

If the data is not returned on any node, then check the replication status on the node.

Next Step

Navigation in the procedure “Deploy Primary/Replica Topology”:

This page was step 4 of 7.

Next: Step 5: Install MariaDB MaxScale

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 5: Install MariaDB MaxScale

Overview

This page details step 5 of the 7-step procedure “Deploy Primary/Replica Topology”.

This step install MariaDB MaxScale 25.01.

The MaxScale node must meet requirements.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Retrieve Customer Download Token

MariaDB Corporation provides package repositories for YUM (RHEL, CentOS), APT (Debian, Ubuntu), and ZYpp (SLES). A download token is required to access the MariaDB Enterprise Repository.

Customer Download Tokens are customer-specific and are available through the MariaDB Customer Portal.

To retrieve the token for your account:

1. Navigate to https://customers.mariadb.com/downloads/token/
2. Log in.
3. Copy the Customer Download Token.

Substitute your token for `CUSTOMER_DOWNLOAD_TOKEN` when configuring the package repositories.

Set Up Repository

1. **On the MaxScale node**, install the prerequisites for downloading the software from the Web.

Install on CentOS / RHEL (YUM):

```
$ sudo yum install curl
```

Install on Debian / Ubuntu (APT):

```
$ sudo apt install curl apt-transport-https
```

Install on SLES (ZYpp):

```
$ sudo zypper install curl
```

2. **On the MaxScale node**, configure package repositories and specify MariaDB MaxScale 25.01:

```
$ curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup

$ echo "${checksum}  mariadb_es_repo_setup" \
       | sha256sum -c -

$ chmod +x mariadb_es_repo_setup

$ sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
      --skip-server \
      --skip-tools \
      --mariadb-maxscale-version="25.01"
```

Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.

Install MaxScale

On the MaxScale node, install MariaDB MaxScale.

Install on CentOS / RHEL (YUM):

```
$ sudo yum install maxscale
```

Install on Debian / Ubuntu (APT):

```
$ sudo apt install maxscale
```

Install on SLES (ZYpp):

```
$ sudo zypper install maxscale
```

Next Step

Navigation in the procedure “Deploy Primary/Replica Topology”:

This page was step 5 of 7.

Next: Step 6: Start and Configure MariaDB MaxScale

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 6: Start and Configure MariaDB MaxScale

Overview

This page details step 6 of the 7-step procedure “Deploy Primary/Replica Topology”.

This step starts and configures MariaDB MaxScale.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Replace the Default Configuration File

MariaDB MaxScale installations include a configuration file with some example objects. This configuration file should be replaced.

On the MaxScale node, replace the default `/etc/maxscale.cnf` with the following configuration:

```
[maxscale]
threads          = auto
admin_host       = 0.0.0.0
admin_secure_gui = false
```

For additional information, see "Global Settings".

Restart MaxScale

On the MaxScale node, restart the MaxScale service to ensure that MaxScale picks up the new configuration:

```
$ sudo systemctl restart maxscale
```

For additional information, see "Starting and Stopping MariaDB".

Configure Server Objects

On the MaxScale node, use maxctrl create server to create a server object for each MariaDB Enterprise Server:

```
$ maxctrl create server node1 192.0.2.101

$ maxctrl create server node2 192.0.2.102

$ maxctrl create server node3 192.0.2.103
```

Configure MariaDB Monitor

MaxScale uses monitors to retrieve additional information from the servers. This information is used by other services in filtering and routing connections based on the current state of the node. For MariaDB Replication, use the MariaDB Monitor (mariadbmon).

On the MaxScale node, use maxctrl create monitor to create a MariaDB Monitor:

```
$ maxctrl create monitor mdb_monitor mariadbmon \
     user=mxs \
     password='MAXSCALE_USER_PASSWORD' \
     replication_user=repl \
     replication_password='REPLICATION_USER_PASSWORD' \
     --servers node1 node2 node3
```

In this example:

- `mdb_monitor` is an arbitrary name that is used to identify the new monitor.
- mariadbmon is the name of the module that implements the MariaDB Monitor.
- `user=MAXSCALE_USER` sets the `user` parameter to the database user account that MaxScale uses to monitor the ES nodes.
- `password='MAXSCALE_USER_PASSWORD'` sets the `password` parameter to the password used by the database user account that MaxScale uses to monitor the ES nodes.
- `replication_user=REPLICATION_USER` sets the `replication_user` parameter to the database user account that MaxScale uses to setup replication.
- `replication_password='REPLICATION_USER_PASSWORD'` sets the `replication_password` parameter to the password used by the database user account that MaxScale uses to setup replication.
- `--servers` sets the `servers` parameter to the set of nodes that MaxScale should monitor. All non-option arguments after `--servers` are interpreted as server names.
- Other Module Parameters supported by `mariadbmon` in MaxScale can also be specified.

Choose a MaxScale Router

Routers control how MaxScale balances the load between Enterprise Server nodes. Each router uses a different approach to routing queries. Consider the specific use case of your application and database load and select the router that best suits

Router	Configuration Procedure	Description
Read Connection (readconnroute)	Configure Read Connection Router	**Connection-based load balancing** • Routes connections to Enterprise ColumnStore nodes designated as replica servers for a read-only pool • Routes connections to an Enterprise ColumnStore node designated as the primary server for a read-write pool.
Read/Write Split (readwritesplit)	Configure Read/Write Split	**Query-based load balancing** • Routes write queries to an Enterprise ColumnStore node designated as the primary server • Routes read queries to Enterprise ColumnStore node designated as replica servers • Automatically reconnects after node failures • Automatically replays transactions after node failures • Optionally enforces causal reads

Configure Read Connection Router

Use MaxScale Read Connection Router (readconnroute) to route connections to replica servers for a read-only pool.

On the MaxScale node, use `maxctrl create service` to create a router:

```
$ maxctrl create service connection_router_service readconnroute \
     user=mxs \
     password='MAXSCALE_USER_PASSWORD' \
     router_options=slave \
     --servers node1 node2 node3
```

In this example:

- `connection_router_service` is an arbitrary name that is used to identify the new service.
- `readconnroute` is the name of the module that implements the Read Connection Router.
- `user=MAXSCALE_USER` sets the `user` parameter to the database user account that MaxScale uses to connect to the ES nodes.
- `password=MAXSCALE_USER_PASSWORD` sets the password parameter to the password used by the database user account that MaxScale uses to connect to the ES nodes.
- `router_options=slave` sets the `router_options` parameter to `slave`, so that MaxScale only routes connections to the replica nodes.
- `--servers sets the servers` parameter to the set of nodes to which MaxScale should route connections. All non-option arguments after `--servers` are interpreted as server names.
- Other Module Parameters supported by `readconnroute` in MaxScale 25.01 can also be specified.

Configure Listener for the Read Connection Router

These instructions reference TCP port 3308. You can use a different TCP port. The TCP port used must not be bound by any other listener.

On the MaxScale node, use the maxctrl create listener command to configure MaxScale to use a listener for the Read Connection Router (readconnroute):

```
$ maxctrl create listener connection_router_service connection_router_listener 3308 \
     protocol=MariaDBClient
```

In this example:

- `connection_router_service` is the name of the readconnroute service that was previously created.
- `connection_router_listener` is an arbitrary name that is used to identify the new listener.
- `3308` is the TCP port.
- `protocol=MariaDBClient` sets the protocol parameter.
- Other Module Parameters supported by listeners in MaxScale can also be specified.

Configure Read/Write Split Router for Queries

MaxScale Read/Write Split Router (readwritesplit) performs query-based load balancing. The router routes write queries to the primary and read queries to the replicas.

On the MaxScale node, use the maxctrl create service command to configure MaxScale to use the Read/Write Split Router (readwritesplit):

```
$ maxctrl create service query_router_service readwritesplit  \
     user=mxs \
     password='MAXSCALE_USER_PASSWORD' \
     --servers node1 node2 node3
```

In this example:

- `query_router_service` is an arbitrary name that is used to identify the new service.
- `readwritesplit` is the name of the module that implements the Read/Write Split Router.
- `user=MAXSCALE_USER` sets the `user` parameter to the database user account that MaxScale uses to connect to the ES nodes.
- `password=MAXSCALE_USER_PASSWORD` sets the `password` parameter to the password used by the database user account that MaxScale uses to connect to the ES nodes.
- `--servers sets the servers` parameter to the set of nodes to which MaxScale should route queries. All non-option arguments after `--servers` are interpreted as server names.
- Other Module Parameters supported by `readwritesplit` in MaxScale can also be specified.

Configure a Listener for the Read/Write Split Router

These instructions reference TCP port `3307`. You can use a different TCP port. The TCP port used must not be bound by any other listener.

On the MaxScale node, use the `maxctrl create listener` command to configure MaxScale to use a listener for the Read/Write Split Router (readwritesplit):

```
$ maxctrl create listener query_router_service query_router_listener 3307 \
     protocol=MariaDBClient
```

In this example:

- `query_router_service` is the name of the `readwritesplit` service that was previously created.
- `query_router_listener` is an arbitrary name that is used to identify the new listener.
- 3307 is the TCP port.

- `protocol=MariaDBClient` sets the `protocol` parameter.
- Other Module Parameters supported by listeners in MaxScale can also be specified.

Start Services

To start the services and monitors, on the MaxScale node use maxctrl start services:

```
$ maxctrl start services
```

Next Step

Navigation in the procedure “Deploy Primary/Replica Topology”:

This page was step 6 of 7.

Next: Step 7: Test MariaDB MaxScale

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 7: Test MariaDB MaxScale

Overview

This page details step 7 of the 7-step procedure “Deploy Primary/Replica Topology”.

This step tests MariaDB MaxScale.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Check Global Configuration

Use maxctrl show maxscale command to view the global MaxScale configuration.

This action is performed on the MaxScale node:

```
$ maxctrl show maxscale
```

```

└──────────────┴─────────────────────────────────────────────────────────┘
```

Output should align to the global MaxScale configuration in the new configuration file you created.

Check Server Configuration

Use the maxctrl list servers and maxctrl show server commands to view the configured server objects.

This action is performed on the MaxScale node:

1. Obtain the full list of servers objects:

```
$ maxctrl list servers
```

```
┌────────┬─────────────┬──────┬─────────────┬─────────────────────────┬──────┐
│ Server │ Address     │ Port │ Connections │ State                   │ GTID │
├────────┼─────────────┼──────┼─────────────┼─────────────────────────┼──────┤
│ node1  │ 192.0.2.101 │ 3306 │ 0           │ Slave, Synced, Running  │      │
├────────┼─────────────┼──────┼─────────────┼─────────────────────────┼──────┤
│ node2  │ 192.0.2.102 │ 3306 │ 0           │ Slave, Synced, Running  │      │
├────────┼─────────────┼──────┼─────────────┼─────────────────────────┼──────┤
│ node3  │ 192.0.2.103 │ 3306 │ 0           │ Master, Synced, Running │      │
└────────┴─────────────┴──────┴─────────────┴─────────────────────────┴──────┘
```

2. For each server object, view the configuration:

```
$ maxctrl show server node3
```

```
┌──────────────────┬──────────────────────────────────────────────────────────┐
│ Server           │ node3                                                    │

└──────────────────────┴─────────────────────────────────────────────────────────────────────┘
```

Output should align to the Read Connection Router (readconnroute) or Read/Write Split Router (readwritesplit) configuration you performed.

Test Application User

Applications should use a dedicated user account. The user account must be created on the primary server.

When users connect to MaxScale, MaxScale authenticates the user connection before routing it to an Enterprise Server node. Enterprise Server authenticates the connection as originating from the IP address of the MaxScale node.

The application users must have one user account with the host IP address of the application server and a second user account with the host IP address of the MaxScale node.

The requirement of a duplicate user account can be avoided by enabling the `proxy_protocol` parameter for MaxScale and the proxy_protocol_networks for Enterprise Server.

Create a User to Connect from MaxScale

This action is performed on any Enterprise Cluster node:

1. Connect to the node:

```
$ sudo mariadb
```

2. Create the database user account for your MaxScale node:

```
CREATE USER 'app_user'@'192.0.2.104' IDENTIFIED BY 'app_user_passwd';
```

Replace 192.0.2.104 with the relevant IP address specification for your MaxScale node.

Passwords should meet your organization's password policies.

3. Grant the privileges required by your application to the database user account for your MaxScale node:

```
GRANT ALL ON test.* TO 'app_user'@'192.0.2.104';
```

The privileges shown are designed to allow the tests in the subsequent sections to work. The user account for your production application may require different privileges.

Create a User to Connect from the Application Server

This action is performed on any Enterprise Cluster node:

1. Create the database user account for your application server:

```
CREATE USER 'app_user'@'192.0.2.11' IDENTIFIED BY 'app_user_passwd';
```

Replace 192.0.2.11 with the relevant IP address specification for your application server.

Passwords should meet your organization's password policies.

2. Grant the privileges required by your application to the database user account for your application server:

```
GRANT ALL ON test.* TO 'app_user'@'192.0.2.11';
```

The privileges shown are designed to allow the tests in the subsequent sections to work. The user account for your production application may require different privileges.

Test Connection with Application User

To test the connection, use the MariaDB Client from your application server to connect to an Enterprise Cluster node through MaxScale.

This action is performed on the application server:

```
$ mariadb --host 192.0.2.104 --port 3307
      --user app_user --password
```

Test Connection with Read Connection Router

If you configured the Read Connection Router, confirm that MaxScale routes connections to the replica servers.

1. On the MaxScale node, use the maxctrl list listeners command to view the available listeners and ports:

```
$ maxctrl list listeners
```

```
┌─────────────────────────────┬──────┬──────┬─────────┬──────────────────────────┐
│ Name                        │ Port │ Host │ State   │ Service                  │
├─────────────────────────────┼──────┼──────┼─────────┼──────────────────────────┤
│ connection_router_listener  │ 3308 │ ::   │ Running │ connection_router_service │
├─────────────────────────────┼──────┼──────┼─────────┼──────────────────────────┤
│ query_router_listener       │ 3307 │ ::   │ Running │ query_router_service      │
└─────────────────────────────┴──────┴──────┴─────────┴──────────────────────────┘
```

2. Open multiple terminals connected to your application server, in each use MariaDB Client to connect to the listener port for the Read Connection Router (in the example 3308):

```
$ mariadb --host 192.0.2.104 --port 3308 \
      --user app_user --password
```

Use the application user credentials you created for the `--user` and `--password` options.

3. In each terminal, query the hostname system variable to identify to which you're connected:

```
SELECT @@global.hostname;

+-------------------+
| @@global.hostname |
+-------------------+
|             node2 |
+-------------------+
```

Different terminals should return different values since MaxScale routes the connections to different nodes.

Since the router was configured the slave router option, the Read Connection Router only routes connections to replica servers.

Test Write Queries with the Read/Write Split Router

If you configured the Read/Write Split Router, confirm that readwritesplit correctly routes write queries.

This action is performed with multiple client connections to the MaxScale node.

1. On the MaxScale node, use the maxctrl list servers command to identify the Enterprise Cluster node currently operating as the primary server:

```
$ maxctrl list servers
```

```
┌────────┬───────────────┬──────┬─────────────┬─────────────────────────┬──────┐
│ Server │ Address       │ Port │ Connections │ State                   │ GTID │
├────────┼───────────────┼──────┼─────────────┼─────────────────────────┼──────┤
│ node1  │ 192.0.2.101 │ 3306 │ 0           │ Slave, Synced, Running  │      │
├────────┼───────────────┼──────┼─────────────┼─────────────────────────┼──────┤
│ node2  │ 192.0.2.102 │ 3306 │ 0           │ Slave, Synced, Running  │      │
├────────┼───────────────┼──────┼─────────────┼─────────────────────────┼──────┤
│ node3  │ 192.0.2.103 │ 3306 │ 0           │ Master, Synced, Running │      │
└────────┴───────────────┴──────┴─────────────┴─────────────────────────┴──────┘
```

The server listed as Master is currently operating as the primary server.

2. On the MaxScale node, use the maxctrl list listeners command to identify the correct listener port:

```
$ maxctrl list listeners galerarouter
```

```
┌──────────────────────────────┬──────┬──────┬─────────┬──────────────────────────────┐
│ Name                         │ Port │ Host │ State   │ Service                      │
├──────────────────────────────┼──────┼──────┼─────────┼──────────────────────────────┤
│ connection_router_listener │ 3308 │      │ Running │ connection_router_service │
│ query_router_listener      │ 3307 │      │ Running │ query_router_service      │
└──────────────────────────────┴──────┴──────┴─────────┴──────────────────────────────┘
```

In the example, the listener port for the Read/Write Split router is 3307.

3. Use the MariaDB Client to establish multiple connections to the listener configured for the Read/Write Split routing service, `query_router_listener`, on the MaxScale node:

```
$ mariadb --host=192.0.2.104 --port=3307 \
      --user=app_user --password=app_user_passwd
```

The database user account for your application server should be specified by the `--user` option.

4. Using any client connection, create a test table:

```
CREATE TABLE test.load_balancing_test (
   id INT PRIMARY KEY AUTO_INCREMENT,
   hostname VARCHAR(256)
);
```

5. Using each client connection, insert the values of the hostname system variable into the table using the INSERT statement to identify the node that executes the statement:

```
INSERT INTO test.load_balancing_test (hostname)
VALUES (@@global.hostname);
```

6. Using any client connection, query the table using the SELECT statement:

```
SELECT * FROM test.load_balancing_test;
```

```
+----+----------+
| id | hostname |
+----+----------+
|  1 | node3    |
|  4 | node3    |
|  7 | node3    |
+----+----------+
```

The output shows the hostname from the Enterprise Cluster node operating as the primary server. (Enterprise Cluster offsets auto-increment values by node to avoid write conflicts.)

Confirm that MaxScale is routing write queries to the Enterprise Cluster node operating as the primary server by checking that the test table only contains the hostname of the correct Enterprise Cluster node.

Test Read Queries with the Read/Write Split Router

If you configured the Read/Write Split Router, confirm that readwritesplit properly routes read queries to multiple replica servers.

This action is performed with multiple clients connected to the MaxScale node.

1. On the MaxScale node, use maxctrl list servers to identify the Enterprise Cluster nodes that are currently operating as replica servers:

```
$ maxctrl list servers
```

```
┌────────┬─────────────┬──────┬─────────────┬─────────────────────────┬──────┐
│ Server │ Address     │ Port │ Connections │ State                   │ GTID │
├────────┼─────────────┼──────┼─────────────┼─────────────────────────┼──────┤
│ node1  │ 192.0.2.101 │ 3306 │ 0           │ Slave, Synced, Running  │      │
├────────┼─────────────┼──────┼─────────────┼─────────────────────────┼──────┤
│ node2  │ 192.0.2.102 │ 3306 │ 0           │ Slave, Synced, Running  │      │
├────────┼─────────────┼──────┼─────────────┼─────────────────────────┼──────┤
│ node3  │ 192.0.2.103 │ 3306 │ 0           │ Master, Synced, Running │      │
└────────┴─────────────┴──────┴─────────────┴─────────────────────────┴──────┘
```

The servers listed as Slave are currently operating as replica servers.

2. On the MaxScale node, use the maxctrl list listeners command to identify the correct listener port:

```
$ maxctrl list listeners
```

```
┌──────────────────────────────┬──────┬──────┬─────────┬──────────────────────────┐
| Name                         | Port | Host | State   | Service                  |
├──────────────────────────────┼──────┼──────┼─────────┼──────────────────────────┤
| connection_router_listener | 3308 |      | Running | connection_router_service |
| query_router_listener      | 3307 |      | Running | query_router_service      |
└──────────────────────────────┴──────┴──────┴─────────┴──────────────────────────┘
```

In the example, the listener port for the Read/Write Split router is 3307.

3. Use the MariaDB Client to establish multiple connections to `query_router_listener` which is the listener configured for the Read/Write Split routing service on the MaxScale node:

```
$ mariadb --host=192.0.2.104 --port=3307 \
   --user=app_user --password=app_user_passwd
```

The database user account for your application server should be specified by the –user option.

4. Using each client connection, query the hostname system variable to identify the node that executes the statement:

```
SELECT @@global.hostname;

+-------------------+
| @@global.hostname |
+-------------------+
|             node2 |
+-------------------+
```

Confirm that MaxScale routes the SELECT statements to different replica servers.

For more information on different routing criteria, see `slave_selection_criteria`

Next Step

Navigation in the procedure “Deploy Primary/Replica Topology”:

This page was step 7 of 7.

This procedure is complete.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Single Node Topologies

Overview

Installation and configuration instructions are available for the deployment of single-node topologies of MariaDB Enterprise Server and MariaDB Community Server.

MariaDB ColumnStore

See Community Server with ColumnStore.

These instructions detail a single-node deployment of a columnar data store, for MariaDB Community Server, with data optionally stored on S3-compatible object storage.

For high availability and scalability, see “Enterprise ColumnStore with Object Storage” or “Enterprise ColumnStore with Shared Local Storage”.

MariaDB Community Server

See Community Server.

These instructions detail a single-node deployment of MariaDB Community Server.

MariaDB Enterprise ColumnStore with Local Storage

See Enterprise Server with ColumnStore (Local Storage).

These instructions detail a single-node deployment of a columnar data store.

For high availability and scalability, see “Enterprise ColumnStore with Shared Local Storage”.

MariaDB Enterprise ColumnStore with Object Storage

See Enterprise Server with ColumnStore (Object Storage).

These instructions detail a single-node deployment of a columnar data store for MariaDB Enterprise Server, with data stored on S3-compatible object storage.

For high availability and scalability, see “Enterprise ColumnStore with Object Storage”.

MariaDB Enterprise Server

See Installing MariaDB Enterprise Server.

These instructions detail a single-node deployment of MariaDB Enterprise Server.

Community Server

Overview

These instructions detail the deployment of **MariaDB Community Server 10.5** in a **Single Standalone Server** configuration on a range of supported Operating Systems.

These instructions detail how to deploy a single-node row database, which is suited for a transactional or OLTP workload that does not require high availability (HA). This deployment type is generally for non-production use cases, such as for development and testing.

MariaDB Community Server Components

These instructions detail the deployment of the following MariaDB Community Server components:

Component	Description
InnoDB	• It is a general purpose storage engine. • It is ACID-compliant. • It is performant. • It is the transactional component of MariaDB’s single stack Hybrid Transactional/Analytical Processing (HTAP) solution.

Term Definitions

Term	Definition
row database	• A database where all columns of each row are stored together. • Best suited for transactional and OLTP workloads. • Also known as a “row-oriented database”.

Installation

MariaDB Corporation provides package repositories for YUM (RHEL, CentOS), APT (Debian, Ubuntu), and ZYpp (SLES).

Install via YUM (CentOS, RHEL)

1. Configure the YUM package repository.

   Prefix the version with `mariadb-` and pass the version string to the `--mariadb-server-version` flag to mariadb_repo_setup. The following directions reference `11.4`.

   To configure YUM package repositories:

   ```
   $ sudo yum install curl
   ```

   ```
   $ curl -LsSO https://r.mariadb.com/downloads/mariadb_repo_setup
   ```

   ```
   $ echo "${checksum} mariadb_repo_setup" \
       | sha256sum -c -
   ```

   ```
   $ chmod +x mariadb_repo_setup
   ```

   ```
   $ sudo ./mariadb_repo_setup \
      --mariadb-server-version="mariadb-11.4"
   ```

   1. *Checksums of the various releases of the `mariadb_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.*

2. Install MariaDB Community Server and package dependencies:

   ```
   $ sudo yum install MariaDB-server MariaDB-backup
   ```

3. Configure MariaDB.

   Installation only loads MariaDB Community Server to the system. MariaDB Community Server requires configuration before the database server is ready for use.

   See Configuration.

Install via APT (Debian, Ubuntu)

1. Configure the APT package repository.

   Prefix the version with `mariadb-` and pass the version string to the `--mariadb-server-version` flag to mariadb_repo_setup. The following directions reference `11.4`.

   To configure APT package repositories:

   ```
   $ sudo apt install curl
   ```

   ```
   $ curl -LsSO https://r.mariadb.com/downloads/mariadb_repo_setup
   ```

   ```
   $ echo "${checksum} mariadb_repo_setup" \
       | sha256sum -c -
   ```

```
$ chmod +x mariadb_repo_setup
```

```
$ sudo ./mariadb_repo_setup \
   --mariadb-server-version="mariadb-11.4"
```

```
$ sudo apt update
```

1. *Checksums of the various releases of the `mariadb_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.*

2. Install MariaDB Community Server and package dependencies:

```
$ sudo apt install mariadb-server mariadb-backup
```

3. Configure MariaDB.

   Installation only loads MariaDB Community Server to the system. MariaDB Community Server requires configuration before the database server is ready for use.

   See Configuration.

Install via ZYpp (SLES)

1. Configure the ZYpp package repository.

   Prefix the version with `mariadb-` and pass the version string to the `--mariadb-server-version` flag to mariadb_repo_setup. The following directions reference `11.4`.

   To configure ZYpp package repositories:

```
$ sudo zypper install curl
```

```
$ curl -LsSO https://r.mariadb.com/downloads/mariadb_repo_setup
```

```
$ echo "${checksum} mariadb_repo_setup" \
    | sha256sum -c -
```

```
$ chmod +x mariadb_repo_setup
```

```
$ sudo ./mariadb_repo_setup \
   --mariadb-server-version="mariadb-11.4"
```

1. *Checksums of the various releases of the `mariadb_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.*

2. Install MariaDB Community Server and package dependencies:

```
$ sudo zypper install MariaDB-server MariaDB-backup
```

3. Configure MariaDB.

   Installation only loads MariaDB Community Server to the system. MariaDB Community Server requires configuration before the database server is ready for use.

   See Configuration.

Configuration

MariaDB Community Server can be configured in the following ways:

- System variables and options can be set in a configuration file (such as `/etc/my.cnf`). MariaDB Community Server must be restarted to apply changes made to the configuration file.
- System variables and options can be set on the command-line.
- If a system variable supports dynamic changes, then it can be set on-the-fly using the SET statement.

Configuration Files

MariaDB's packages include several bundled configuration files. It is also possible to create custom configuration files.

On RHEL, CentOS, and SLES, MariaDB's packages bundle the following configuration files:

- `/etc/my.cnf`
- `/etc/my.cnf.d/client.cnf`
- `/etc/my.cnf.d/mysql-clients.cnf`
- `/etc/my.cnf.d/server.cnf`

And on RHEL, CentOS, and SLES, custom configuration files from the following directories are read by default:

- `/etc/my.cnf.d/`

On Debian and Ubuntu, MariaDB's packages bundle the following configuration files:

- `/etc/mysql/my.cnf`
- `/etc/mysql/mariadb.cnf`
- `/etc/mysql/mariadb.conf.d/50-client.cnf`
- `/etc/mysql/mariadb.conf.d/50-mysql-clients.cnf`
- `/etc/mysql/mariadb.conf.d/50-mysqld_safe.cnf`
- `/etc/mysql/mariadb.conf.d/50-server.cnf`
- `/etc/mysql/mariadb.conf.d/60-galera.cnf`

And on Debian and Ubuntu, custom configuration files from the following directories are read by default:

- `/etc/mysql/conf.d/`
- `/etc/mysql/mariadb.conf.d/`

Configuring MariaDB

1. Determine which system variables and options you need to configure.

   Useful system variables and options for MariaDB Community Server include:

System Variable/Option	Description
datadir	Sets the path to the data directory. MariaDB Community Server writes data files to this directory, including tablespaces, logs, and schemas. Change it to use a non-standard location or to start the Server on a different data directory for testing.
bind_address	Sets the local TCP/IP address on which MariaDB Community Server listens for incoming connections. When testing on a local system, bind the address to the local host at `127.0.0.1` to prevent network access.
port	Sets the port MariaDB Community Server listens on. Use this system variable to use a non-standard port or when running multiple Servers on the same host for testing.

System Variable/Option	Description
max_connections	Sets the maximum number of simultaneous connections MariaDB Community Server allows.
thread_handling	Sets how MariaDB Community Server handles threads for client connections.
log_error	Sets the file name for the error log.
innodb_buffer_pool_size	Sets the amount of memory InnoDB reserves for the Buffer Pool.
innodb_log_file_size	Sets the size for each Redo Log file and innodb_log_files_in_group sets the number of Redo Log files used by InnoDB.
innodb_io_capacity	Sets the maximum number of I/O operations per second that InnoDB can use.

2. Choose a configuration file in which to configure your system variables and options.

   It is not recommended to make custom changes to one of the bundled configuration files. Instead, it is recommended to create a custom configuration file in one of the included directories. Configuration files in included directories are read in alphabetical order. If you want your custom configuration file to override the bundled configuration files, then it is a good idea to prefix the custom configuration file's name with a string that will be sorted last, such as `z-`.

   - On RHEL, CentOS, and SLES, a good custom configuration file would be: `/etc/my.cnf.d/z-custom-my.cnf`
   - On Debian and Ubuntu, a good custom configuration file would be: `/etc/mysql/mariadb.conf.d/z-custom-my.cnf`

3. Set your system variables and options in the configuration file.

   They need to be set in a group that will be read by mariadbd, such as `[mariadb]` or `[server]`.

   For example:

```
[mariadb]
log_error                = mariadb-test.err
innodb_buffer_pool_size   = 1G
```

Starting the Server

MariaDB Community Server includes configuration to start, stop, restart, enable/disable on boot, and check the status of the Server using the operating system default process management system.

For distributions that use `systemd` (most supported OSes), you can manage the Server process using the `systemctl` command:

Operation	Command
Start	`sudo systemctl start mariadb`
Stop	`sudo systemctl stop mariadb`
Restart	`sudo systemctl restart mariadb`
Enable during startup	`sudo systemctl enable mariadb`
Disable during startup	`sudo systemctl disable mariadb`
Status	`sudo systemctl status mariadb`

Testing

When MariaDB Community Server is up and running on your system, you should test that it is working and there weren't any issues during startup.

1. Connect to the Server using mariadb Client using the `root@localhost` user account:

```
$ sudo mariadb
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 38
Server version: 10.5.28-MariaDB MariaDB Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]>
```

Community Server with ColumnStore

These instructions detail the deployment of **MariaDB ColumnStore 6** with **MariaDB Community Server 10.6** in a **Single-node ColumnStore Deployment** configuration on a range of supported Operating Systems.

These instructions detail how to deploy a single-node columnar database, which is suited for an analytical or OLAP workload that does not require high availability (HA). This deployment type is generally for non-production use cases, such as for development and testing.

Community Server Components

These instructions detail the deployment of the following MariaDB Community Server components:

Component	Description
MariaDB ColumnStore 6	• It is a columnar storage engine that provides distributed, columnar storage for scalable analytical processing and smart transactions. • It is the analytical component of MariaDB's single stack Hybrid Transactional/Analytical Processing (HTAP) solution.

Term Definitions

Term	Definition
columnar database	• A database where the columns of each row are stored separately. • Best suited for analytical and OLAP workloads. • Also known as a "column-oriented database".
row database	• A database where all columns of each row are stored together. • Best suited for transactional and OLTP workloads. • Also known as a "row-oriented database".

High Availability

Single-node ColumnStore 6 does not support high availability.

For high availability and scalability, instead see "ColumnStore Object Storage Topology" or "ColumnStore Shared Local Storage Topology".

System Preparation

Systems hosting a ColumnStore deployment requires some additional configuration prior to installation:

1. Optimize Linux kernel parameters
2. Configure the Linux security module to support installation
3. Configure the character encoding
4. Optionally configure S3-compatible storage

Optimize Linux Kernel Parameters

MariaDB ColumnStore performs best when certain Linux kernel parameters are optimized.

1. Set the relevant kernel parameters in a sysctl configuration file. For proper change management, we recommend setting them in a ColumnStore-specific configuration file.

   For example, create a `/etc/sysctl.d/90-mariadb-columnstore.conf` file with the following contents:

   ```
   # minimize swapping
   vm.swappiness = 1

   # Increase the TCP max buffer size
   net.core.rmem_max = 16777216
   net.core.wmem_max = 16777216

   # Increase the TCP buffer limits
   # min, default, and max number of bytes to use
   net.ipv4.tcp_rmem = 4096 87380 16777216
   net.ipv4.tcp_wmem = 4096 65536 16777216

   # don't cache ssthresh from previous connection
   net.ipv4.tcp_no_metrics_save = 1

   # for 1 GigE, increase this to 2500
   # for 10 GigE, increase this to 30000
   net.core.netdev_max_backlog = 2500
   ```

2. Set the same kernel parameters at runtime using the `sysctl` command:

   ```
   $ sudo sysctl --load=/etc/sysctl.d/90-mariadb-columnstore.conf
   ```

LSM Configuration for Install

To avoid confusion and potential problems, we recommend configuring the system's Linux Security Module (LSM) during installation. The specific steps to configure the security module will depend on the platform.

In the Configure the Linux Security Module section, we will configure the security module and restart it.

SELinux (RHEL, CentOS)

SELinux must be set to `permissive` mode before installing MariaDB ColumnStore.

1. Set SELinux to permissive mode by setting `SELINUX=permissive` in `/etc/selinux/config`.

   For example, the file will usually look like this after the change:

```
# This file controls the state of SELinux on the system.
# SELINUX= can take one of these three values:
#     enforcing - SELinux security policy is enforced.
#     permissive - SELinux prints warnings instead of enforcing.
#     disabled - No SELinux policy is loaded.
SELINUX=permissive
# SELINUXTYPE= can take one of three values:
#     targeted - Targeted processes are protected,
#     minimum - Modification of targeted policy. Only selected processes are protected.
#     mls - Multi Level Security protection.
SELINUXTYPE=targeted
```

2. Reboot the system.
3. Confirm that SELinux is in `permissive` mode using `getenforce`:

```
$ sudo getenforce
```

```
Permissive
```

Note:

Remember to configure and re-enable SELinux after the installation is complete.

AppArmor (Debian, Ubuntu)

AppArmor must be disabled before installing MariaDB ColumnStore.

1. Disable AppArmor:

```
$ sudo systemctl disable apparmor
```

2. Reboot the system.
3. Confirm that no AppArmor profiles are loaded using `aa-status`:

```
$ sudo aa-status
```

Example output:

```
apparmor module is loaded.
0 profiles are loaded.
0 profiles are in enforce mode.
0 profiles are in complain mode.
0 processes have profiles defined.
0 processes are in enforce mode.
0 processes are in complain mode.
0 processes are unconfined but have a profile defined.
```

Note:

Remember to configure and re-enable AppArmor after the installation is complete.

Configure the Character Encoding

When using MariaDB ColumnStore, it is recommended to set the system's locale to UTF-8.

1. On RHEL 8, install additional dependencies.

```
$ sudo yum install glibc-locale-source glibc-langpack-en
```

2. Set the system's locale to `en_US.UTF-8` by executing `localedef`:

```
$ sudo localedef -i en_US -f UTF-8 en_US.UTF-8
```

S3-Compatible Storage

MariaDB ColumnStore supports S3-compatible object storage.

S3-compatible object storage is optional, but **highly recommended**.

S3-compatible object storage is:

- **Compatible**: Many object storage services are compatible with the Amazon S3 API.
- **Economical**: S3-compatible object storage is often very low cost.
- **Flexible**: S3-compatible object storage is available for both cloud and on-premises deployments.
- **Limitless**: S3-compatible object storage is often virtually limitless.
- **Resilient**: S3-compatible object storage is often low maintenance and highly available, since many services use resilient cloud infrastructure.
- **Scalable**: S3-compatible object storage is often highly optimized for read and write scaling.
- **Secure**: S3-compatible object storage is often encrypted-at-rest.

Many S3-compatible object storage services exist. MariaDB Corporation cannot make guarantees about all S3-compatible object storage services, because different services provide different functionality.

If you have any questions about using specific S3-compatible object storage with MariaDB ColumnStore, contact us.

Create an S3 Bucket

If you want to use S3-compatible storage, it is important to create the S3 bucket before you start ColumnStore.

If you already have an S3 bucket, confirm that the bucket is empty.

We will configure ColumnStore to use the S3 bucket later in the Configure the S3 Storage Manager section.

> **Note:**
>
> The specific steps to create the S3 bucket will depend on what S3-compatible storage you are using.

ColumnStore Installation

MariaDB Corporation provides package repositories for YUM (RHEL, CentOS) and APT (Debian, Ubuntu).

MariaDB ColumnStore ships as a storage engine plugin for MariaDB Community Server and a platform engine to handle back-end storage processes. MariaDB Community Server 10.6 does not require any additional software to operate as a single-node analytics database.

Install ColumnStore via YUM (RHEL, CentOS)

1. Configure the YUM package repository.

   MariaDB ColumnStore `6` is available on MariaDB Community Server `10.6`.

   To configure YUM package repositories:

   ```
   $ sudo yum install curl
   ```

   ```
   $ curl -LsSO https://r.mariadb.com/downloads/mariadb_repo_setup
   ```

```
$ echo "${checksum} mariadb_repo_setup" \
    | sha256sum -c -
```

```
$ chmod +x mariadb_repo_setup
```

```
$ sudo ./mariadb_repo_setup \
   --mariadb-server-version="mariadb-10.6"
```

1. *Checksums of the various releases of the `mariadb_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.*

2. Install the EPEL repository:

```
$ sudo yum install epel-release
```

3. Install some additional dependencies for ColumnStore:

```
$ sudo yum install jemalloc
```

4. Install MariaDB ColumnStore and package dependencies:

```
$ sudo yum install MariaDB-server MariaDB-backup \
   MariaDB-shared MariaDB-client \
   MariaDB-columnstore-engine
```

5. Configure MariaDB ColumnStore.

   Installation only loads MariaDB ColumnStore to the system. MariaDB ColumnStore requires configuration and additional post-installation steps before the database server is ready for use.

   See ColumnStore Configuration.

Install ColumnStore via APT (Debian, Ubuntu)

1. Configure the APT package repository.

   MariaDB ColumnStore `6` is available on MariaDB Community Server `10.6`.

   To configure APT package repositories:

```
$ sudo apt install curl
```

```
$ curl -LsSO https://r.mariadb.com/downloads/mariadb_repo_setup
```

```
$ echo "${checksum} mariadb_repo_setup" \
    | sha256sum -c -
```

```
$ chmod +x mariadb_repo_setup
```

```
$ sudo ./mariadb_repo_setup \
   --mariadb-server-version="mariadb-10.6"
```

```
$ sudo apt update
```

1. *Checksums of the various releases of the `mariadb_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.*

2. Install some additional dependencies for ColumnStore.

   On Debian 10 and Ubuntu 20.04, install the following:

   ```
   $ sudo apt install libjemalloc2
   ```

   On Debian 9 and Ubuntu 18.04, install the following:

   ```
   $ sudo apt install libjemalloc1
   ```

3. Install MariaDB ColumnStore and package dependencies:

   ```
   $ sudo apt install mariadb-server mariadb-backup \
      libmariadb3 mariadb-client \
      mariadb-plugin-columnstore
   ```

4. Configure MariaDB ColumnStore.

   Installation only loads MariaDB ColumnStore to the system. MariaDB ColumnStore requires configuration and additional post-installation steps before the database server is ready for use.

   See ColumnStore Configuration.

ColumnStore Configuration

MariaDB ColumnStore requires configuration after it is installed. The configuration file location depends on your operating system.

Community Server Configuration

MariaDB Community Server can be configured in the following ways:

- System variables and options can be set in a configuration file (such as `/etc/my.cnf`). MariaDB Community Server must be restarted to apply changes made to the configuration file.
- System variables and options can be set on the command-line.
- If a system variable supports dynamic changes, then it can be set on-the-fly using the SET statement.

Configuration Files

MariaDB's packages include several bundled configuration files. It is also possible to create custom configuration files.

On RHEL and CentOS, MariaDB's packages bundle the following configuration files:

- `/etc/my.cnf`
- `/etc/my.cnf.d/client.cnf`
- `/etc/my.cnf.d/mysql-clients.cnf`
- `/etc/my.cnf.d/server.cnf`

And on RHEL and CentOS, custom configuration files from the following directories are read by default:

- `/etc/my.cnf.d/`

On Debian and Ubuntu, MariaDB's packages bundle the following configuration files:

- `/etc/mysql/my.cnf`

- `/etc/mysql/mariadb.cnf`
- `/etc/mysql/mariadb.conf.d/50-client.cnf`
- `/etc/mysql/mariadb.conf.d/50-mysql-clients.cnf`
- `/etc/mysql/mariadb.conf.d/50-mysqld_safe.cnf`
- `/etc/mysql/mariadb.conf.d/50-server.cnf`
- `/etc/mysql/mariadb.conf.d/60-galera.cnf`

And on Debian and Ubuntu, custom configuration files from the following directories are read by default:

- `/etc/mysql/conf.d/`
- `/etc/mysql/mariadb.conf.d/`

Configuring MariaDB for ColumnStore

1. Determine which system variables and options you need to configure.

   Mandatory system variables and options for single-node MariaDB ColumnStore include:

Connector	MariaDB Connector/R2DBC
character_set_server	Set this system variable to `utf8`
collation_server	Set this system variable to `utf8_general_ci`
loose-columnstore_use_import_for_batchinsert	Set this system variable to `ALWAYS` to always use `cpimport` for LOAD DATA INFILE and INSERT…SELECT statements.

> **Warning:**
>
> The `loose-` prefix is required for ColumnStore system variables in the configuration file. Without it, MariaDB Server will fail to start if the ColumnStore plugin is not installed or has been removed.

1. Choose a configuration file in which to configure your system variables and options.

We recommend **not** making custom changes to one of the bundled configuration files. Instead, create a custom configuration file in one of the included directories. Configuration files in included directories are read in alphabetical order. If you want your custom configuration file to override the bundled configuration files, it is a good idea to prefix the custom configuration file's name with a string that will be sorted last, such as `z-`.

- On RHEL and CentOS, a good custom configuration file would be: `/etc/my.cnf.d/z-custom-my.cnf`
- On Debian and Ubuntu, a good custom configuration file would be: `/etc/mysql/mariadb.conf.d/z-custom-my.cnf`

3. Set your system variables and options in the configuration file.

   They need to be set in a group that will be read by mariadbd, such as `[mariadb]` or `[server]`.

   For example:

```
[mariadb]
log_error                       = mariadbd.err
character_set_server            = utf8
collation_server                = utf8_general_ci
```

Configure Cross Engine Joins

When a cross engine join is executed, the ExeMgr process connects to the server using the `root` user with no password by default. MariaDB Community Server 10.6 will reject this login attempt by default. If you plan to use

Cross Engine Joins, you need to configure ColumnStore to use a different user account and password. These directions are for configuring the cross engine join user. Directions for creating the cross engine join user are in the Create the Cross Engine Join User section.

To configure cross engine joins, perform the following steps, use the mcsSetConfig command.

For example, to configure ColumnStore to use the `cross_engine` user account to connect to the server at `127.0.0.1`:

```
$ sudo mcsSetConfig CrossEngineSupport Host 127.0.0.1
$ sudo mcsSetConfig CrossEngineSupport Port 3306
$ sudo mcsSetConfig CrossEngineSupport User cross_engine
$ sudo mcsSetConfig CrossEngineSupport Password cross_engine_passwd
```

> **Note:**
>
> Please choose a password that meets your organization's password policies. If your MariaDB Community Server instance has a password validation plugin installed, then the password should also meet the configured requirements.

Configure the S3 Storage Manager

MariaDB ColumnStore can use S3-compatible storage, but it is not required. S3-compatible storage must be configured before it can be used.

To configure ColumnStore to use S3-compatible storage, edit `/etc/columnstore/storagemanager.cnf`:

```
[ObjectStorage]
…
service = S3
…
[S3]
bucket = your_columnstore_bucket_name
endpoint = your_s3_endpoint
aws_access_key_id = your_s3_access_key_id
aws_secret_access_key = your_s3_secret_key
# iam_role_name = your_iam_role
# sts_region = your_sts_region
# sts_endpoint = your_sts_endpoint

[Cache]
cache_size = your_local_cache_size
path = your_local_cache_path
```

- The default local cache size is 2 GB.
- The default local cache path is `/var/lib/columnstore/storagemanager/cache`.
- Ensure that the local cache path has sufficient store space to store the local cache.
- The `bucket` option must be set to the name of the bucket that you created in the Create an S3 Bucket step.
- To use an IAM role, you must also uncomment and set `iam_role_name`, `sts_region`, and `sts_endpoint`.

Start the ColumnStore Processes

The Community Server and ColumnStore processes can be started using the `systemctl` command. In case the processes were started during the installation process, use the restart command to ensure that the processes pick up the new configuration. Perform the following procedure.

1. Start the MariaDB Community Server process and configure it to start automatically:

   ```
   $ sudo systemctl restart mariadb
   ```

```
$ sudo systemctl enable mariadb
```

2. Start the MariaDB ColumnStore processes and configure them to start automatically:

```
$ sudo systemctl restart mariadb-columnstore
```

```
$ sudo systemctl enable mariadb-columnstore
```

Create User Accounts

For single-node ColumnStore deployments, only a single user account needs to be created.

Create the Cross Engine Join User

The credentials for cross engine joins were previously configured in the Cross Engine Joins section. The user account must also be created and granted the necessary privileges to access data.

1. Connect to the server using MariaDB Client using the `root@localhost` user account:

```
$ sudo mariadb
```

2. Create the user account with the CREATE USER statement:

```
CREATE USER 'cross_engine'@'127.0.0.1'
   IDENTIFIED BY "cross_engine_passwd";
```

```
CREATE USER 'cross_engine'@'localhost'
   IDENTIFIED BY "cross_engine_passwd";
```

Note:

Please choose the same user name and password that was configured in the Cross Engine Joins section.

1. Grant the user account `SELECT` privileges on all databases with the GRANT statement:

```
GRANT SELECT, PROCESS ON *.*
   TO 'cross_engine'@'127.0.0.1';
```

```
GRANT SELECT, PROCESS ON *.*
   TO 'cross_engine'@'localhost';
```

Bulk Import Data

Now that the ColumnStore system is running, you can bulk import your data.

Import the Schema

Before data can be imported into the tables, the schema needs to be created.

1. Connect to the server using mariadb Client using the `root@localhost` user account:

```
$ sudo mariadb
```

2. For each database that you are importing, create the database with the CREATE DATABASE statement:

```
CREATE DATABASE inventory;
```

3. For each table that you are importing, create the table with the CREATE TABLE statement:

```
CREATE TABLE inventory.products (
   product_name VARCHAR(11) NOT NULL DEFAULT '',
   supplier VARCHAR(128) NOT NULL DEFAULT '',
   quantity VARCHAR(128) NOT NULL DEFAULT '',
   unit_cost VARCHAR(128) NOT NULL DEFAULT ''
) ENGINE=Columnstore DEFAULT CHARSET=utf8;
```

cpimport

MariaDB ColumnStore includes cpimport, which is a command-line utility that is designed to efficiently load data in bulk.

To import your data from a TSV (tab-separated values) file with cpimport:

```
$ sudo cpimport -s '\t' inventory products /tmp/inventory-products.tsv
```

LOAD DATA INFILE

When data is loaded with the LOAD DATA INFILE statement, MariaDB ColumnStore loads the data using cpimport, which is a command-line utility that is designed to efficiently load data in bulk.

To import your data from a TSV (tab-separated values) file with LOAD DATA INFILE statement:

```
LOAD DATA INFILE '/tmp/inventory-products.tsv'
INTO TABLE inventory.products;
```

Import from Remote Database

MariaDB ColumnStore can also import data directly from a remote database. A simple method is to query the table using the SELECT statement, and then pipe the results into cpimport, which is a command-line utility that is designed to efficiently load data in bulk.

To import your data from a remote MariaDB database:

```
$ mariadb --quick \
   --skip-column-names \
   --execute="SELECT * FROM inventory.products" \
   | cpimport -s '\t' inventory products
```

Configure the Linux Security Module

If you stopped the Linux Security Module (LSM) during installation, you can restart the module and configure.

The specific steps to configure the security module depend on the operating system.

Configure SELinux (RHEL, CentOS)

We set SELinux to permissive mode in the SELinux section, but we have to create an SELinux policy for ColumnStore before re-enabling it. This will ensure that SELinux does not interfere with ColumnStore's functionality. A policy can be generated while SELinux is still in permissive mode using the `audit2allow` command.

1. To configure SELinux, you have to install the packages required for `audit2allow`.

   On RHEL 7 and CentOS 7, install the following:

   ```
   $ sudo yum install policycoreutils policycoreutils-python
   ```

   On RHEL 8, install the following:

```
$ sudo yum install policycoreutils python3-policycoreutils policycoreutils-python-utils
```

2. Allow the system to run under load for a while to generate SELinux audit events.
3. After the system has taken some load, generate an SELinux policy from the audit events using `audit2allow`:

```
$ sudo grep mysqld /var/log/audit/audit.log | audit2allow -M mariadb_local
```

If no audit events were found, this will print the following:

```
$ sudo grep mysqld /var/log/audit/audit.log | audit2allow -M mariadb_local
```

```
Nothing to do
```

4. If audit events were found, the new SELinux policy can be loaded using `semodule`:

```
$ sudo semodule -i mariadb_local.pp
```

5. Set SELinux to enforcing mode by setting `SELINUX=enforcing` in `/etc/selinux/config`:

```
# This file controls the state of SELinux on the system.
# SELINUX= can take one of these three values:
#     enforcing - SELinux security policy is enforced.
#     permissive - SELinux prints warnings instead of enforcing.
#     disabled - No SELinux policy is loaded.
SELINUX=enforcing
# SELINUXTYPE= can take one of three values:
#     targeted - Targeted processes are protected,
#     minimum - Modification of targeted policy. Only selected processes are protected.
#     mls - Multi Level Security protection.
SELINUXTYPE=targeted
```

6. Reboot the system.
7. Confirm that SELinux is in enforcing mode using `getenforce`:

```
$ sudo getenforce
```

Configure AppArmor (Debian, Ubuntu)

We disabled AppArmor in the AppArmor section, but we have to create an AppArmor profile for ColumnStore before re-enabling it. This will ensure that AppArmor does not interfere with ColumnStore's functionality.

For information on how to create a profile, see How to create an AppArmor Profile on ubuntu.com.

Administration

ColumnStore has several components. Each of those components needs to be administered.

Community Server Administration

MariaDB Community Server uses `systemctl` to start and stop the server processes:

Operation	Command
Start	`sudo systemctl start mariadb`
Stop	`sudo systemctl stop mariadb`
Restart	`sudo systemctl restart mariadb`
Enable during startup	`sudo systemctl enable mariadb`

Operation	Command
Disable during startup	`sudo systemctl disable mariadb`
Status	`sudo systemctl status mariadb`

ColumnStore Administration

MariaDB ColumnStore uses `systemctl` to start and stop the ColumnStore processes:

Operation	Command
Start	`sudo systemctl start mariadb-columnstore`
Stop	`sudo systemctl stop mariadb-columnstore`
Restart	`sudo systemctl restart mariadb-columnstore`
Enable during startup	`sudo systemctl enable mariadb-columnstore`
Disable during startup	`sudo systemctl disable mariadb-columnstore`
Status	`sudo systemctl status mariadb-columnstore`

Testing

When you have MariaDB ColumnStore up and running, you should test it to ensure that it is in working order and that there were not any issues during startup.

Checking Server Status

1. Connect to the server using mariadb Client using the `root@localhost` user account:

```
$ sudo mariadb
```

```
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 38
Server version: 10.6.21-MariaDB MariaDB Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]>
```

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 1: Prepare Systems for Enterprise ColumnStore Nodes

Step 1: Prepare Systems for Enterprise ColumnStore Nodes

Overview

This page details step 1 of a 5-step procedure for deploying Single-Node Enterprise ColumnStore with Local storage.

This step prepares the system to host MariaDB Enterprise Server and MariaDB Enterprise ColumnStore.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Optimize Linux Kernel Parameters

MariaDB Enterprise ColumnStore performs best with Linux kernel optimizations.

On each server to host an Enterprise ColumnStore node, optimize the kernel:

1. Set the relevant kernel parameters in a sysctl configuration file. To ensure proper change management, use an Enterprise ColumnStore-specific configuration file.

Create a `/etc/sysctl.d/90-mariadb-enterprise-columnstore.conf` file:

```
# minimize swapping
vm.swappiness = 1

# Increase the TCP max buffer size
net.core.rmem_max = 16777216
net.core.wmem_max = 16777216

# Increase the TCP buffer limits
# min, default, and max number of bytes to use
net.ipv4.tcp_rmem = 4096 87380 16777216
net.ipv4.tcp_wmem = 4096 65536 16777216

# don't cache ssthresh from previous connection
net.ipv4.tcp_no_metrics_save = 1

# for 1 GigE, increase this to 2500
# for 10 GigE, increase this to 30000
net.core.netdev_max_backlog = 2500
```

2. Use the `sysctl` command to set the kernel parameters at runtime

```
$ sudo sysctl --load=/etc/sysctl.d/90-mariadb-enterprise-columnstore.conf
```

Temporarily Configure Linux Security Modules (LSM)

The Linux Security Modules (LSM) should be temporarily disabled on each Enterprise ColumnStore node during installation.

The LSM will be configured and re-enabled later in this deployment procedure.

The steps to disable the LSM depend on the specific LSM used by the operating system.

CentOS / RHEL Stop SELinux

SELinux must be set to permissive mode before installing MariaDB Enterprise ColumnStore.

To set SELinux to permissive mode:

1. Set SELinux to permissive mode:

```
$ sudo setenforce permissive
```

2. Set SELinux to permissive mode by setting SELINUX=permissive in /etc/selinux/config.

For example, the file will usually look like this after the change:

```
# This file controls the state of SELinux on the system.
# SELINUX= can take one of these three values:
#     enforcing - SELinux security policy is enforced.
#     permissive - SELinux prints warnings instead of enforcing.
#     disabled - No SELinux policy is loaded.
SELINUX=permissive
# SELINUXTYPE= can take one of three values:
#     targeted - Targeted processes are protected,
#     minimum - Modification of targeted policy. Only selected processes are protected.
#     mls - Multi Level Security protection.
SELINUXTYPE=targeted
```

3. Confirm that SELinux is in permissive mode:

```
$ sudo getenforce
Permissive
```

SELinux will be configured and re-enabled later in this deployment procedure. This configuration is not persistent. If you restart the server before configuring and re-enabling SELinux later in the deployment procedure, you must reset the enforcement to permissive mode.

Debian / Ubuntu AppArmor

AppArmor must be disabled before installing MariaDB Enterprise ColumnStore.

1. Disable AppArmor:

```
$ sudo systemctl disable apparmor
```

2. Reboot the system.
3. Confirm that no AppArmor profiles are loaded using aa-status:

```
$ sudo aa-status
```

```
apparmor module is loaded.
0 profiles are loaded.
0 profiles are in enforce mode.
0 profiles are in complain mode.
0 processes have profiles defined.
0 processes are in enforce mode.
0 processes are in complain mode.
0 processes are unconfined but have a profile defined.
```

AppArmor will be configured and re-enabled later in this deployment procedure.

Configure Character Encoding

When using MariaDB Enterprise ColumnStore, it is recommended to set the system's locale to UTF-8.

1. On RHEL 8, install additional dependencies:

```
$ sudo yum install glibc-locale-source glibc-langpack-en
```

2. Set the system's locale to en_US.UTF-8 by executing localedef:

```
$ sudo localedef -i en_US -f UTF-8 en_US.UTF-8
```

Next Step

Navigation in the Single-Node Enterprise ColumnStore topology with Local storage deployment procedure:

This page was step 1 of 5.

Next: Step 2: Install MariaDB Enterprise ColumnStore.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 2: Install Enterprise ColumnStore

Overview

This page details step 2 of a 5-step procedure for deploying Single-Node Enterprise ColumnStore with Local storage.

This step installs MariaDB Enterprise Server and MariaDB Enterprise ColumnStore 23.10.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Retrieve Download Token

MariaDB Corporation provides package repositories for CentOS / RHEL (YUM) and Debian / Ubuntu (APT). A download token is required to access the MariaDB Enterprise Repository.

Customer Download Tokens are customer-specific and are available through the MariaDB Customer Portal.

To retrieve the token for your account:

1. Navigate to https://customers.mariadb.com/downloads/token/
2. Log in.
3. Copy the Customer Download Token.

Substitute your token for `CUSTOMER_DOWNLOAD_TOKEN` when configuring the package repositories.

Set Up Repository

1. On each Enterprise ColumnStore node, install the prerequisites for downloading the software from the Web. Install on CentOS / RHEL (YUM):

```
$ sudo yum install curl
```

Install on Debian / Ubuntu (APT):

```
$ sudo apt install curl apt-transport-https
```

2. On each Enterprise ColumnStore node, configure package repositories and specify Enterprise Server:

```
$ curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
```

```
$ echo "${checksum}  mariadb_es_repo_setup" \

 | sha256sum -c -
```

```
$ chmod +x mariadb_es_repo_setup
```

```
$ sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
      --skip-maxscale \
      --skip-tools \
      --mariadb-server-version="11.4"
```

Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.

Install Enterprise ColumnStore

Install additional dependencies:

Install on CentOS / RHEL (YUM)

```
$ sudo yum install epel-release

$ sudo yum install jemalloc
```

Install of Debian 10 and Ubuntu 20.04 (APT):

```
$ sudo apt install libjemalloc2
```

Install on Debian 9 and Ubuntu 18.04 (APT):

```
$ sudo apt install libjemalloc1
```

Install MariaDB Enterprise Server and MariaDB Enterprise ColumnStore:

Install on CentOS / RHEL (YUM):

```
$ sudo yum install MariaDB-server \
   MariaDB-backup \
   MariaDB-shared \
   MariaDB-client \
   MariaDB-columnstore-engine
```

Install on Debian / Ubuntu (APT):

```
$ sudo apt install mariadb-server \
   mariadb-backup \
   libmariadb3 \
   mariadb-client \
   mariadb-plugin-columnstore
```

Next Step

Navigation in the Single-Node Enterprise ColumnStore topology with Local storage deployment procedure:

This page was step 2 of 5.

Next: Step 3: Start and Configure MariaDB Enterprise ColumnStore.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 3: Start and Configure Enterprise ColumnStore

Overview

This page details step 3 of a 5-step procedure for deploying Single-Node Enterprise ColumnStore with Local storage.

This step starts and configures MariaDB Enterprise Server and MariaDB Enterprise ColumnStore 23.10.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Configure Enterprise ColumnStore

Mandatory system variables and options for Single-Node Enterprise ColumnStore include:

Connector	MariaDB Connector/R2DBC
character_set_server	Set this system variable to `utf8`
collation_server	Set this system variable to `utf8_general_ci`

Connector	MariaDB Connector/R2DBC
loose-columnstore_use_import_for_batchinsert	Set this system variable to `ALWAYS` to always use `cpimport` for LOAD DATA INFILE and INSERT…SELECT statements.

Warning:

The `loose-` prefix is required for ColumnStore system variables in the configuration file. Without it, MariaDB Server will fail to start if the ColumnStore plugin is not installed or has been removed.

Example Configuration

```
[mariadb]
log_error                               = mariadbd.err
character_set_server                    = utf8
collation_server                        = utf8_general_ci
```

Start the Enterprise ColumnStore Services

Start and enable the MariaDB Enterprise Server service, so that it starts automatically upon reboot:

```
$ sudo systemctl start mariadb

$ sudo systemctl enable mariadb
```

Start and enable the MariaDB Enterprise ColumnStore service, so that it starts automatically upon reboot:

```
$ sudo systemctl start mariadb-columnstore

$ sudo systemctl enable mariadb-columnstore
```

Create the Utility User

Enterprise ColumnStore requires a mandatory utility user account. By default, it connects to the server using the root user with no password. MariaDB Enterprise Server 10.6 will reject this login attempt by default, so you will need to configure Enterprise ColumnStore to use a different user account and password and create this user account on Enterprise Server.

1. On the Enterprise ColumnStore node, create the user account with the CREATE USER statement:

```
CREATE USER 'util_user'@'127.0.0.1'
IDENTIFIED BY 'util_user_passwd';
```

2. On the Enterprise ColumnStore node, grant the user account SELECT privileges on all databases with the GRANT statement:

```
GRANT SELECT, PROCESS ON *.*
TO 'util_user'@'127.0.0.1';
```

3. Configure Enterprise ColumnStore to use the utility user:

```
$ sudo mcsSetConfig CrossEngineSupport Host 127.0.0.1

$ sudo mcsSetConfig CrossEngineSupport Port 3306

$ sudo mcsSetConfig CrossEngineSupport User util_user
```

4. Set the password:

```
$ sudo mcsSetConfig CrossEngineSupport Password util_user_passwd
```

For details about how to encrypt the password, see "Credentials Management for MariaDB Enterprise ColumnStore".

Passwords should meet your organization's password policies. If your MariaDB Enterprise Server instance has a password validation plugin installed, then the password should also meet the configured requirements.

Configure Linux Security Modules (LSM)

The specific steps to configure the security module depend on the operating system.

Configure SELinux (CentOS, RHEL)

Configure SELinux for Enterprise ColumnStore:

1. To configure SELinux, you have to install the packages required for audit2allow.
   On CentOS 7 and RHEL 7, install the following:

```
$ sudo yum install policycoreutils policycoreutils-python
```

On RHEL 8, install the following:

```
$ sudo yum install policycoreutils python3-policycoreutils policycoreutils-python-utils
```

2. Allow the system to run under load for a while to generate SELinux audit events.
3. After the system has taken some load, generate an SELinux policy from the audit events using audit2allow:

```
$ sudo grep mysqld /var/log/audit/audit.log | audit2allow -M mariadb_local
```

If no audit events were found, this will print the following:

```
$ sudo grep mysqld /var/log/audit/audit.log | audit2allow -M mariadb_local

Nothing to do
```

4. If audit events were found, the new SELinux policy can be loaded using semodule:

```
$ sudo semodule -i mariadb_local.pp
```

5. Set SELinux to enforcing mode by setting SELINUX=enforcing in /etc/selinux/config.

For example, the file will usually look like this after the change:

```
# This file controls the state of SELinux on the system.
# SELINUX= can take one of these three values:
#     enforcing - SELinux security policy is enforced.
#     permissive - SELinux prints warnings instead of enforcing.
#     disabled - No SELinux policy is loaded.
SELINUX=enforcing
# SELINUXTYPE= can take one of three values:
#     targeted - Targeted processes are protected,
#     minimum - Modification of targeted policy. Only selected processes are protected.
#     mls - Multi Level Security protection.
SELINUXTYPE=targeted
```

6. Set SELinux to enforcing mode:

```
$ sudo setenforce enforcing
```

Configure AppArmor (Ubuntu)

For information on how to create a profile, see How to create an AppArmor Profile on ubuntu.com.

Next Step

Navigation in the Single-Node Enterprise ColumnStore topology with Local storage deployment procedure:

This page was step 3 of 5.

Next: Step 4: Test MariaDB Enterprise ColumnStore.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 4: Test Enterprise ColumnStore

Overview

This page details step 4 of a 5-step procedure for deploying Single-Node Enterprise ColumnStore with Local storage.

This step tests MariaDB Enterprise Server and MariaDB Enterprise ColumnStore 23.10.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Test Local Connection

Connect to the server using MariaDB Client using the root@localhost user account:

```
$ sudo mariadb
```

```
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 38
Server version: 11.4.5-3-MariaDB-Enterprise MariaDB Enterprise Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]>
```

Test ColumnStore Plugin Status

Query information_schema.PLUGINS and confirm that the ColumnStore storage engine plugin is `ACTIVE`:

```
SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM information_schema.PLUGINS
WHERE PLUGIN_LIBRARY LIKE 'ha_columnstore%';
```

```
+--------------------+---------------+
| PLUGIN_NAME        | PLUGIN_STATUS |
+--------------------+---------------+
| Columnstore        | ACTIVE        |
| COLUMNSTORE_COLUMNS | ACTIVE        |
| COLUMNSTORE_TABLES  | ACTIVE        |
| COLUMNSTORE_FILES   | ACTIVE        |
| COLUMNSTORE_EXTENTS | ACTIVE        |
+--------------------+---------------+
```

Test ColumnStore Table Creation

1. Create a test database, if it does not exist:

```
CREATE DATABASE IF NOT EXISTS test;
```

2. Create a ColumnStore table:

```
CREATE TABLE IF NOT EXISTS test.contacts (
   first_name VARCHAR(50),
   last_name VARCHAR(50),
   email VARCHAR(100)
) ENGINE=ColumnStore;
```

3. Add sample data into the table:

```
INSERT INTO test.contacts (first_name, last_name, email)
   VALUES
   ("Kai", "Devi", "kai.devi@example.com"),
   ("Lee", "Wang", "lee.wang@example.com");
```

4. Read data from table:

```
SELECT * FROM test.contacts;
```

```
+------------+-----------+----------------------+
| first_name | last_name | email                |
+------------+-----------+----------------------+
| Kai        | Devi      | kai.devi@example.com |
| Lee        | Wang      | lee.wang@example.com |
+------------+-----------+----------------------+
```

Test Cross Engine Join

1. Create an InnoDB table:

```
CREATE TABLE test.addresses (
   email VARCHAR(100),
   street_address VARCHAR(255),
   city VARCHAR(100),
   state_code VARCHAR(2)
) ENGINE = InnoDB;
```

2. Add data to the table:

```
INSERT INTO test.addresses (email, street_address, city, state_code)
   VALUES
   ("kai.devi@example.com", "1660 Amphibious Blvd.", "Redwood City", "CA"),
   ("lee.wang@example.com", "32620 Little Blvd", "Redwood City", "CA");
```

3. Perform a cross-engine join:

```
SELECT name AS "Name", addr AS "Address"
FROM (SELECT CONCAT(first_name, " ", last_name) AS name,
   email FROM test.contacts) AS contacts
INNER JOIN (SELECT CONCAT(street_address, ", ", city, ", ", state_code) AS addr,
   email FROM test.addresses) AS addr
WHERE  contacts.email = addr.email;
```

```
+----------+----------------------------------------+
| Name     | Address                                |
+----------+----------------------------------------+
| Kai Devi | 1660 Amphibious Blvd., Redwood City, CA |
| Lee Wang | 32620 Little Blvd, Redwood City, CA     |
+----------+----------------------------------------+

+------------------+-------------------------------------+
| Name             | Address                             |
+------------------+-------------------------------------+
| Walker Percy     | 500 Thomas More Dr., Covington, LA  |
| Flannery O'Connor | 300 Tarwater Rd., Milledgeville, GA |
+------------------+-------------------------------------+
```

Next Step

Navigation in the Single-Node Enterprise ColumnStore topology with Local storage deployment procedure:

This page was step 4 of 5.

Next: Step 5: Bulk Import of Data.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 5: Bulk Import of Data

Overview

This page details step 5 of a 5-step procedure for deploying Single-Node Enterprise ColumnStore with Local storage.

This step bulk imports data to Enterprise ColumnStore.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Import the Schema

Before data can be imported into the tables, create a matching schema.

On the primary server, create the schema:

1. For each database that you are importing, create the database with the CREATE DATABASE statement:

```
CREATE DATABASE inventory;
```

2. For each table that you are importing, create the table with the CREATE TABLE statement:

```
CREATE TABLE inventory.products (
   product_name VARCHAR(11) NOT NULL DEFAULT '',
   supplier VARCHAR(128) NOT NULL DEFAULT '',
   quantity VARCHAR(128) NOT NULL DEFAULT '',
   unit_cost VARCHAR(128) NOT NULL DEFAULT ''
) ENGINE=Columnstore DEFAULT CHARSET=utf8;
```

Import the Data

Enterprise ColumnStore supports multiple methods to import data into ColumnStore tables.

cpimport

MariaDB Enterprise ColumnStore includes cpimport, which is a command-line utility designed to efficiently load data in bulk. Alternative methods are available.

To import your data from a TSV (tab-separated values) file, on the primary server run cpimport:

```
$ sudo cpimport -s '\t' inventory products /tmp/inventory-products.tsv
```

LOAD DATA INFILE

When data is loaded with the LOAD DATA INFILE statement, MariaDB Enterprise ColumnStore loads the data using cpimport, which is a command-line utility designed to efficiently load data in bulk. Alternative methods are available.

To import your data from a TSV (tab-separated values) file, on the primary server use LOAD DATA INFILE statement:

```
LOAD DATA INFILE '/tmp/inventory-products.tsv'
INTO TABLE inventory.products;
```

Import from Remote Database

MariaDB Enterprise ColumnStore can also import data directly from a remote database. A simple method is to query the table using the SELECT statement, and then pipe the results into cpimport, which is a command-line utility that is designed to efficiently load data in bulk. Alternative methods are available.

To import your data from a remote MariaDB database:

```
$ mariadb --quick \
   --skip-column-names \
   --execute="SELECT * FROM inventory.products" \
   | cpimport -s '\t' inventory products
```

Next Step

Navigation in the Single-Node Enterprise ColumnStore topology with Local storage deployment procedure:

This page was step 5 of 5.

This procedure is complete.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 1: Prepare Systems for Enterprise ColumnStore Nodes

Overview

This page details step 1 of a 5-step procedure for deploying Single-Node Enterprise ColumnStore with Object storage.

This step prepares the system to host MariaDB Enterprise Server and MariaDB Enterprise ColumnStore 23.10.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Optimize Linux Kernel Parameters

MariaDB Enterprise ColumnStore performs best with Linux kernel optimizations.

On each server to host an Enterprise ColumnStore node, optimize the kernel:

1. Set the relevant kernel parameters in a sysctl configuration file. To ensure proper change management, use an Enterprise ColumnStore-specific configuration file.

Create a `/etc/sysctl.d/90-mariadb-enterprise-columnstore.conf` file:

```
# minimize swapping
vm.swappiness = 1

# Increase the TCP max buffer size
net.core.rmem_max = 16777216
net.core.wmem_max = 16777216

# Increase the TCP buffer limits
# min, default, and max number of bytes to use
net.ipv4.tcp_rmem = 4096 87380 16777216
net.ipv4.tcp_wmem = 4096 65536 16777216

# don't cache ssthresh from previous connection
net.ipv4.tcp_no_metrics_save = 1

# for 1 GigE, increase this to 2500
# for 10 GigE, increase this to 30000
net.core.netdev_max_backlog = 2500
```

2. Use the sysctl command to set the kernel parameters at runtime

```
$ sudo sysctl --load=/etc/sysctl.d/90-mariadb-enterprise-columnstore.conf
```

Temporarily Configure Linux Security Modules (LSM)

The Linux Security Modules (LSM) should be temporarily disabled on each Enterprise ColumnStore node during installation.

The LSM will be configured and re-enabled later in this deployment procedure.

The steps to disable the LSM depend on the specific LSM used by the operating system.

CentOS / RHEL Stop SELinux

SELinux must be set to permissive mode before installing MariaDB Enterprise ColumnStore.

To set SELinux to permissive mode:

1. Set SELinux to permissive mode:

```
$ sudo setenforce permissive
```

2. Set SELinux to permissive mode by setting SELINUX=permissive in /etc/selinux/config.

For example, the file will usually look like this after the change:

```
# This file controls the state of SELinux on the system.
# SELINUX= can take one of these three values:
#     enforcing - SELinux security policy is enforced.
#     permissive - SELinux prints warnings instead of enforcing.
#     disabled - No SELinux policy is loaded.
SELINUX=permissive
# SELINUXTYPE= can take one of three values:
#     targeted - Targeted processes are protected,
#     minimum - Modification of targeted policy. Only selected processes are protected.
#     mls - Multi Level Security protection.
SELINUXTYPE=targeted
```

3. Confirm that SELinux is in permissive mode:

```
$ sudo getenforce
Permissive
```

SELinux will be configured and re-enabled later in this deployment procedure. This configuration is not persistent. If you restart the server before configuring and re-enabling SELinux later in the deployment procedure, you must reset the enforcement to permissive mode.

Debian / Ubuntu AppArmor

AppArmor must be disabled before installing MariaDB Enterprise ColumnStore.

1. Disable AppArmor:

```
$ sudo systemctl disable apparmor
```

2. Reboot the system.
3. Confirm that no AppArmor profiles are loaded using aa-status:

```
$ sudo aa-status
```

```
apparmor module is loaded.
0 profiles are loaded.
0 profiles are in enforce mode.
0 profiles are in complain mode.
0 processes have profiles defined.
0 processes are in enforce mode.
0 processes are in complain mode.
0 processes are unconfined but have a profile defined.
```

AppArmor will be configured and re-enabled later in this deployment procedure.

Configure Character Encoding

When using MariaDB Enterprise ColumnStore, it is recommended to set the system's locale to UTF-8.

1. On RHEL 8, install additional dependencies:

```
$ sudo yum install glibc-locale-source glibc-langpack-en
```

2. Set the system's locale to en_US.UTF-8 by executing localedef:

```
$ sudo localedef -i en_US -f UTF-8 en_US.UTF-8
```

Create an S3 Bucket

If you want to use S3-compatible storage, it is important to create the S3 bucket before you start ColumnStore.

If you already have an S3 bucket, confirm that the bucket is empty.

S3 bucket configuration will be performed later in this procedure.

Next Step

Navigation in the Single-Node Enterprise ColumnStore topology with Object storage deployment procedure:

This page was step 1 of 5.

Next: Step 2: Install MariaDB Enterprise ColumnStore.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 2: Install Enterprise ColumnStore

Overview

This page details step 2 of a 5-step procedure for deploying Single-Node Enterprise ColumnStore with Object storage.

This step installs MariaDB Enterprise Server and MariaDB Enterprise ColumnStore 23.10.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Retrieve Download Token

MariaDB Corporation provides package repositories for CentOS / RHEL (YUM) and Debian / Ubuntu (APT). A download token is required to access the MariaDB Enterprise Repository.

Customer Download Tokens are customer-specific and are available through the MariaDB Customer Portal.

To retrieve the token for your account:

1. Navigate to https://customers.mariadb.com/downloads/token/
2. Log in.
3. Copy the Customer Download Token.

Substitute your token for `CUSTOMER_DOWNLOAD_TOKEN` when configuring the package repositories.

Set Up Repository

1. On each Enterprise ColumnStore node, install the prerequisites for downloading the software from the Web. Install on CentOS / RHEL (YUM):

```
$ sudo yum install curl
```

Install on Debian / Ubuntu (APT):

```
$ sudo apt install curl apt-transport-https
```

2. On each Enterprise ColumnStore node, configure package repositories and specify Enterprise Server:

```
$ curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
```

```
$ echo "${checksum}  mariadb_es_repo_setup" \

 | sha256sum -c -
```

```
$ chmod +x mariadb_es_repo_setup
```

```
$ sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
      --skip-maxscale \
      --skip-tools \
      --mariadb-server-version="11.4"
```

Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.

Install Enterprise ColumnStore

Install additional dependencies:

Install on CentOS / RHEL (YUM)

```
$ sudo yum install epel-release

$ sudo yum install jemalloc
```

Install of Debian 10 and Ubuntu 20.04 (APT):

```
$ sudo apt install libjemalloc2
```

Install on Debian 9 and Ubuntu 18.04 (APT):

```
$ sudo apt install libjemalloc1
```

Install MariaDB Enterprise Server and MariaDB Enterprise ColumnStore:

Install on CentOS / RHEL (YUM):

```
$ sudo yum install MariaDB-server \
   MariaDB-backup \
   MariaDB-shared \
   MariaDB-client \
   MariaDB-columnstore-engine
```

Install on Debian / Ubuntu (APT):

```
$ sudo apt install mariadb-server \
   mariadb-backup \
   libmariadb3 \
   mariadb-client \
   mariadb-plugin-columnstore
```

Next Step

Navigation in the Single-Node Enterprise ColumnStore topology with Object storage deployment procedure:

This page was step 2 of 5.

Next: Step 3: Start and Configure MariaDB Enterprise ColumnStore.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 3: Start and Configure Enterprise ColumnStore

Overview

This page details step 3 of a 5-step procedure for deploying Single-Node Enterprise ColumnStore with Object storage.

This step starts and configures MariaDB Enterprise Server and MariaDB Enterprise ColumnStore 23.10.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Configure Enterprise ColumnStore

Mandatory system variables and options for Single-Node Enterprise ColumnStore include:

Connector	MariaDB Connector/R2DBC
character_set_server	Set this system variable to `utf8`
collation_server	Set this system variable to `utf8_general_ci`

Connector	MariaDB Connector/R2DBC
loose-columnstore_use_import_for_batchinsert	Set this system variable to `ALWAYS` to always use `cpimport` for LOAD DATA INFILE and INSERT…SELECT statements.

Warning:

The `loose-` prefix is required for ColumnStore system variables in the configuration file. Without it, MariaDB Server will fail to start if the ColumnStore plugin is not installed or has been removed.

Example Configuration

```
[mariadb]
log_error                              = mariadbd.err
character_set_server                   = utf8
collation_server                       = utf8_general_ci
```

Configure the S3 Storage Manager

Configure Enterprise ColumnStore S3 Storage Manager to use S3-compatible storage by editing the `/etc/columnstore/storagemanager.cnf` configuration file:

```
[ObjectStorage]
…
service = S3
…
[S3]
bucket                = your_columnstore_bucket_name
endpoint              = your_s3_endpoint
aws_access_key_id     = your_s3_access_key_id
aws_secret_access_key = your_s3_secret_key
# iam_role_name       = your_iam_role
# sts_region          = your_sts_region
# sts_endpoint        = your_sts_endpoint
# ec2_iam_mode        = enabled

[Cache]
cache_size = your_local_cache_size
path       = your_local_cache_path
```

The S3-compatible object storage options are configured under `[S3]`:

- The `bucket` option must be set to the name of the bucket that you created in "Create an S3 Bucket".
- The `endpoint` option must be set to the endpoint for the S3-compatible object storage.
- The `aws_access_key_id` and `aws_secret_access_key` options must be set to the access key ID and secret access key for the S3-compatible object storage.
- To use a specific IAM role, you must uncomment and set `iam_role_name`, `sts_region`, and `sts_endpoint`.
- To use the IAM role assigned to an EC2 instance, you must uncomment `ec2_iam_mode=enabled`.

The local cache options are configured under [Cache]:

- The `cache_size` option is set to 2 GB by default.
- The `path` option is set to `/var/lib/columnstore/storagemanager/cache` by default.

Ensure that the specified path has sufficient storage space for the specified cache size.

Start the Enterprise ColumnStore Services

Start and enable the MariaDB Enterprise Server service, so that it starts automatically upon reboot:

```
$ sudo systemctl start mariadb

$ sudo systemctl enable mariadb
```

Start and enable the MariaDB Enterprise ColumnStore service, so that it starts automatically upon reboot:

```
$ sudo systemctl start mariadb-columnstore

$ sudo systemctl enable mariadb-columnstore
```

Create the Utility User

Enterprise ColumnStore requires a mandatory utility user account to perform cross-engine joins and similar operations.

1. Create the user account with the CREATE USER statement:

```
CREATE USER 'util_user'@'127.0.0.1'
IDENTIFIED BY 'util_user_passwd';
```

2. Grant the user account `SELECT` privileges on all databases with the GRANT statement:

```
GRANT SELECT, PROCESS ON *.*
TO 'util_user'@'127.0.0.1';
```

3. Configure Enterprise ColumnStore to use the utility user:

```
$ sudo mcsSetConfig CrossEngineSupport Host 127.0.0.1

$ sudo mcsSetConfig CrossEngineSupport Port 3306

$ sudo mcsSetConfig CrossEngineSupport User util_user
```

4. Set the password:

```
$ sudo mcsSetConfig CrossEngineSupport Password util_user_passwd
```

For details about how to encrypt the password, see "Credentials Management for MariaDB Enterprise ColumnStore".

Passwords should meet your organization's password policies. If your MariaDB Enterprise Server instance has a password validation plugin installed, then the password should also meet the configured requirements.

Configure Linux Security Modules (LSM)

The specific steps to configure the security module depend on the operating system.

Configure SELinux (CentOS, RHEL)

Configure SELinux for Enterprise ColumnStore:

1. To configure SELinux, you have to install the packages required for audit2allow.
   On CentOS 7 and RHEL 7, install the following:

```
$ sudo yum install policycoreutils policycoreutils-python
```

On RHEL 8, install the following:

```
$ sudo yum install policycoreutils python3-policycoreutils policycoreutils-python-utils
```

2. Allow the system to run under load for a while to generate SELinux audit events.
3. After the system has taken some load, generate an SELinux policy from the audit events using audit2allow:

```
$ sudo grep mysqld /var/log/audit/audit.log | audit2allow -M mariadb_local
```

If no audit events were found, this will print the following:

```
$ sudo grep mysqld /var/log/audit/audit.log | audit2allow -M mariadb_local

Nothing to do
```

4. If audit events were found, the new SELinux policy can be loaded using semodule:

```
$ sudo semodule -i mariadb_local.pp
```

5. Set SELinux to enforcing mode by setting `SELINUX=enforcing` in `/etc/selinux/config`.

For example, the file will usually look like this after the change:

```
# This file controls the state of SELinux on the system.
# SELINUX= can take one of these three values:
#     enforcing - SELinux security policy is enforced.
#     permissive - SELinux prints warnings instead of enforcing.
#     disabled - No SELinux policy is loaded.
SELINUX=enforcing
# SELINUXTYPE= can take one of three values:
#     targeted - Targeted processes are protected,
#     minimum - Modification of targeted policy. Only selected processes are protected.
#     mls - Multi Level Security protection.
SELINUXTYPE=targeted
```

6. Set SELinux to enforcing mode:

```
$ sudo setenforce enforcing
```

Configure AppArmor (Ubuntu)

For information on how to create a profile, see How to create an AppArmor Profile on ubuntu.com.

Next Step

Navigation in the Single-Node Enterprise ColumnStore topology with Object storage deployment procedure:

This page was step 3 of 5.

Next: Step 4: Test MariaDB Enterprise ColumnStore.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 4: Test Enterprise ColumnStore

Overview

This page details step 4 of a 5-step procedure for deploying Single-Node Enterprise ColumnStore with Object storage.

This step tests MariaDB Enterprise Server and MariaDB Enterprise ColumnStore 23.10.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Test S3 Connection

MariaDB Enterprise ColumnStore 23.10 includes a testS3Connection command to test the S3 configuration, permissions, and connectivity.

On each Enterprise ColumnStore node, test the S3 configuration:

```
$ sudo testS3Connection
```

```
StorageManager[26887]: Using the config file found at /etc/columnstore/storagemanager.cnf
StorageManager[26887]: S3Storage: S3 connectivity & permissions are OK
S3 Storage Manager Configuration OK
```

If the `testS3Connection` command does not return `OK`, investigate the S3 configuration.

Test Local Connection

Connect to the server using MariaDB Client using the `root@localhost` user account:

```
$ sudo mariadb
```

```
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 38
Server version: 11.4.5-3-MariaDB-Enterprise MariaDB Enterprise Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]>
```

Test ColumnStore Plugin Status

Query information_schema.PLUGINS and confirm that the ColumnStore storage engine plugin is `ACTIVE`:

```
SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM information_schema.PLUGINS
WHERE PLUGIN_LIBRARY LIKE 'ha_columnstore%';
```

```
+---------------------+---------------+
| PLUGIN_NAME         | PLUGIN_STATUS |
+---------------------+---------------+
| Columnstore         | ACTIVE        |
| COLUMNSTORE_COLUMNS | ACTIVE        |
| COLUMNSTORE_TABLES  | ACTIVE        |
| COLUMNSTORE_FILES   | ACTIVE        |
| COLUMNSTORE_EXTENTS | ACTIVE        |
+---------------------+---------------+
```

Test ColumnStore Table Creation

1. Create a test database, if it does not exist:

```
CREATE DATABASE IF NOT EXISTS test;
```

2. Create a ColumnStore table:

```
CREATE TABLE IF NOT EXISTS test.contacts (
   first_name VARCHAR(50),
   last_name VARCHAR(50),
   email VARCHAR(100)
) ENGINE=ColumnStore;
```

3. Add sample data into the table:

```
INSERT INTO test.contacts (first_name, last_name, email)
   VALUES
   ("Kai", "Devi", "kai.devi@example.com"),
   ("Lee", "Wang", "lee.wang@example.com");
```

4. Read data from table:

```
SELECT * FROM test.contacts;

+------------+-----------+----------------------+
| first_name | last_name | email                |
+------------+-----------+----------------------+
| Kai        | Devi      | kai.devi@example.com |
| Lee        | Wang      | lee.wang@example.com |
+------------+-----------+----------------------+
```

Test Cross Engine Join

1. Create an InnoDB table:

```
CREATE TABLE test.addresses (
   email VARCHAR(100),
   street_address VARCHAR(255),
   city VARCHAR(100),
   state_code VARCHAR(2)
) ENGINE = InnoDB;
```

2. Add data to the table:

```
INSERT INTO test.addresses (email, street_address, city, state_code)
   VALUES
   ("kai.devi@example.com", "1660 Amphibious Blvd.", "Redwood City", "CA"),
   ("lee.wang@example.com", "32620 Little Blvd", "Redwood City", "CA");
```

3. Perform a cross-engine join:

```
SELECT name AS "Name", addr AS "Address"
FROM (SELECT CONCAT(first_name, " ", last_name) AS name,
   email FROM test.contacts) AS contacts
INNER JOIN (SELECT CONCAT(street_address, ", ", city, ", ", state_code) AS addr,
   email FROM test.addresses) AS addr
WHERE  contacts.email = addr.email;
```

```
+----------+----------------------------------------+
| Name     | Address                                |
+----------+----------------------------------------+
| Kai Devi | 1660 Amphibious Blvd., Redwood City, CA |
| Lee Wang | 32620 Little Blvd, Redwood City, CA     |
+----------+----------------------------------------+

+------------------+-------------------------------------+
| Name             | Address                             |
+------------------+-------------------------------------+
| Walker Percy     | 500 Thomas More Dr., Covington, LA  |
| Flannery O'Connor | 300 Tarwater Rd., Milledgeville, GA |
+------------------+-------------------------------------+
```

Next Step

Navigation in the Single-Node Enterprise ColumnStore topology with Object storage deployment procedure:

This page was step 4 of 5.

Next: Step 5: Bulk Import of Data.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 5: Bulk Import of Data

Overview

This page details step 5 of a 5-step procedure for deploying Single-Node Enterprise ColumnStore with Object storage.

This step bulk imports data to Enterprise ColumnStore.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Import the Schema

Before data can be imported into the tables, create a matching schema.

On the primary server, create the schema:

1. For each database that you are importing, create the database with the CREATE DATABASE statement:

```
CREATE DATABASE inventory;
```

2. For each table that you are importing, create the table with the CREATE TABLE statement:

```
CREATE TABLE inventory.products (
   product_name VARCHAR(11) NOT NULL DEFAULT '',
   supplier VARCHAR(128) NOT NULL DEFAULT '',
   quantity VARCHAR(128) NOT NULL DEFAULT '',
   unit_cost VARCHAR(128) NOT NULL DEFAULT ''
) ENGINE=Columnstore DEFAULT CHARSET=utf8;
```

Import the Data

Enterprise ColumnStore supports multiple methods to import data into ColumnStore tables.

cpimport

MariaDB Enterprise ColumnStore includes cpimport, which is a command-line utility designed to efficiently load data in bulk. Alternative methods are available.

To import your data from a TSV (tab-separated values) file, on the primary server run cpimport:

```
$ sudo cpimport -s '\t' inventory products /tmp/inventory-products.tsv
```

LOAD DATA INFILE

When data is loaded with the LOAD DATA INFILE statement, MariaDB Enterprise ColumnStore loads the data using cpimport, which is a command-line utility designed to efficiently load data in bulk. Alternative methods are available.

To import your data from a TSV (tab-separated values) file, on the primary server use LOAD DATA INFILE statement:

```
LOAD DATA INFILE '/tmp/inventory-products.tsv'
INTO TABLE inventory.products;
```

Import from Remote Database

MariaDB Enterprise ColumnStore can also import data directly from a remote database. A simple method is to query the table using the SELECT statement, and then pipe the results into cpimport, which is a command-line utility that is designed to efficiently load data in bulk. Alternative methods are available.

To import your data from a remote MariaDB database:

```
$ mariadb --quick \
   --skip-column-names \
   --execute="SELECT * FROM inventory.products" \
   | cpimport -s '\t' inventory products
```

Next Step

Navigation in the Single-Node Enterprise ColumnStore topology with Object storage deployment procedure:

This page was step 5 of 5.

This procedure is complete.

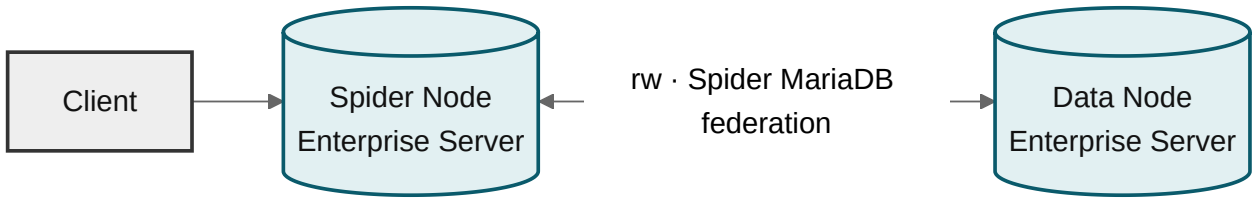
This page is: Copyright © 2026 MariaDB. All rights reserved.

Spider Storage Engine

Spider Topologies

Spider Federated

MariaDB Enterprise Spider enables reading from and writing to tables on remote Enterprise Server nodes. It uses the Spider storage engine for “virtual” Federated Spider Tables, querying Data Tables on Data Nodes (which use non-Spider engines) via a MariaDB foreign data wrapper. This solution supports transactions and is available with Enterprise Server 10.3+.

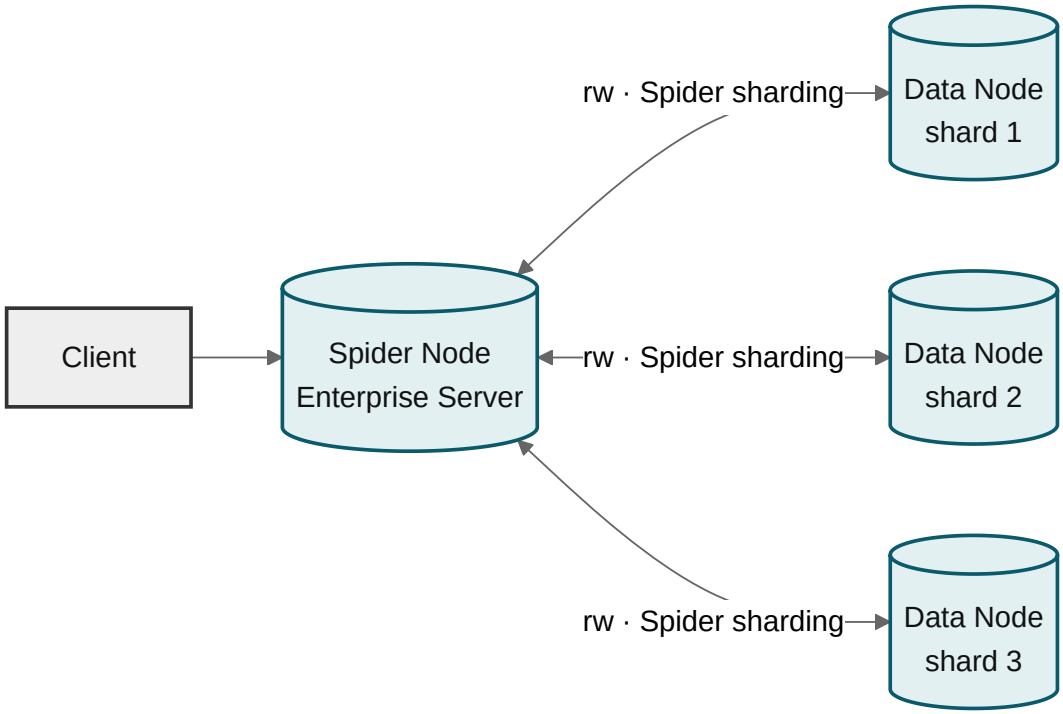


Spider Federated: a Spider Node reads from and writes to a Data Table on a remote Data Node via the Spider MariaDB federation.

- **Read from and write to tables on remote ES nodes**
- Spider Node uses Spider storage engine for Federated Spider Tables
- Federated Spider Table is a “virtual” table
- Spider uses MariaDB foreign data wrapper to query Data Table on Data Node
- Data Node uses non-Spider storage engine for Data Tables
- Supports transactions
- Enterprise Server 10.3+, Enterprise Spider

Spider Sharded

MariaDB Enterprise Spider facilitates horizontal scalability by sharding tables. It uses the Spider storage engine for partitioned “virtual” Sharded Spider Tables, querying Data Tables on Data Nodes (using non-Spider engines) for each partition via a MariaDB foreign data wrapper. This solution supports transactions and is available with Enterprise Server 10.3+.



Spider Sharded: a Spider Node distributes the partitions of a virtual sharded table across multiple Data Nodes (shards) via the Spider foreign data wrapper.

- **Shard tables for horizontal scalability**
- Spider Node uses Spider storage engine for Sharded Spider Tables
- Sharded Spider Table is a partitioned “virtual” table
- Spider uses MariaDB foreign data wrapper to query Data Tables on Data Nodes for each partition
- Data Node uses non-Spider storage engine for Data Tables
- Supports transactions
- Enterprise Server 10.3+, Enterprise Spider

Federated MariaDB Enterprise Spider Topology

Federated MariaDB Enterprise Spider Topology

Overview

In the Federated MariaDB Enterprise Spider topology, a Spider Node contains one or more “virtual” Spider Tables. A Spider Table does not store data. When a Spider Table is queried, the Enterprise Spider storage engine uses a MariaDB foreign data wrapper to read from and write to a Data Table on a Data Node.

Benefits

MariaDB Enterprise Spider:

- Supports a MariaDB foreign data wrapper. The MariaDB foreign data wrapper can be used to replace the older Federated and FederatedX storage engines.
- Supports an ODBC foreign data wrapper in MariaDB Enterprise Server 10.5 and later. The ODBC foreign data wrapper is beta maturity. The maturity can be confirmed by querying the information_schema.SPIDER_WRAPPER_PROTOCOLS table.

The Spider Federated topology:

- Can be used to query tables located on a different MariaDB Enterprise Server node from the Spider Node using the MariaDB foreign data wrapper.
- Can be used to join tables located on a different MariaDB Enterprise Server node with tables on the Spider Node using the MariaDB foreign data wrapper.
- Can be used to migrate tables located on a different MariaDB Enterprise Server node to the Spider Node using the MariaDB foreign data wrapper.

Federated MariaDB Enterprise Spider Topology

In the Spider Federated topology, a Spider Node contains one or more “virtual” Spider Tables. A Spider Table does not store data. When a Spider Table is queried, the Enterprise Spider storage engine uses a MariaDB foreign data wrapper to read from and write to a Data Table on a Data Node.

The Spider Federated topology consists of:

- One MariaDB Enterprise Server node is a Spider Node
- One MariaDB Enterprise Server node is a Data Node

The Spider Node:

- Contains one or more Spider Tables
- Uses the Enterprise Spider storage engine plugin for Spider Tables
- Uses a MariaDB foreign data wrapper to query the Data Table on the Data Node

The Data Node:

- Contains a Data Table for each Spider Table
- Uses a non-Spider storage engine for each Data Table, such as InnoDB or ColumnStore

Term Definitions

Term	Definition
Data Node	A Data Node is a MariaDB Enterprise Server node that contains one or more Data Tables.
Data Table	A Data Table stores data for a Spider Table. When a Spider Table is queried, the Enterprise Spider storage engine uses the MariaDB foreign data wrapper to read from and write to the Data Table on a Data Node. The Data Table must be created on the Data Node with the same structure as the Spider Table. The Data Table must use a non-Spider storage engine, such as InnoDB or ColumnStore.
ODBC Data Source	An ODBC Data Source relies on an ODBC Driver and an ODBC Driver Manager to query an external data source.
ODBC Driver	An ODBC Driver is a library that integrates with a ODBC Driver Manager to query an external data source.
ODBC Driver Manager	An ODBC Driver Manager allows applications to use ODBC Drivers.
Spider Node	A Spider Node is a MariaDB Enterprise Server node that contains one or more Spider Tables.
Spider Table	A Spider Table is a virtual table that does not store data. When a Spider Table is queried, the Enterprise Spider storage engine uses foreign data wrappers to read from and write to Data Tables on Data Nodes or ODBC Data Sources.

Example Use Cases

Query MariaDB Enterprise Server Nodes

The Spider Federated topology can be used to query tables located on another MariaDB Enterprise Server node:

- The MariaDB Enterprise Server node with the desired table is configured as a Data Node.
- The MariaDB Enterprise Server node that needs to query the table is configured as a Spider Node.
- The Data Table is the desired table on the Data Node.
- A Spider Table is created on the Spider Node that references the Data Table on the Data Node.
- On the Spider Node, the Data Table is queried by querying the Spider Table like the following:

```
SELECT * FROM spider_tab;
```

- Non-Spider tables can also be referenced in queries with the Spider Table:

```
SELECT *
FROM spider_tab s
JOIN innodb_tab i
ON s.id=i.id;
```

Migrate Tables from MariaDB Enterprise Server Nodes

The Spider Federated topology can be used to migrate tables from one MariaDB Enterprise Server node to another MariaDB Enterprise Server node:

- The MariaDB Enterprise Server node with the source table is configured as a Data Node.
- The MariaDB Enterprise Server node with the destination table is configured as a Spider Node.
- The Data Table is the source table on the Data Node.
- A Spider Table is created on the Spider Node that references the Data Table on the Data Node.
- On the Spider node, the Data Table's data is migrated to the destination table by querying the Spider Table like the following:

```
INSERT INTO innodb_tab
   SELECT * FROM spider_tab;
```

Examples

Load Spider with Configuration File (ES 10.4+)

```
[mariadb]
...
plugin_load_add = "ha_spider"
```

Load Spider with INSTALL SONAME (ES 10.4+)

```
INSTALL SONAME "ha_spider";
```

View Foreign Data Wrappers (ES 10.5+)

```
SELECT * FROM information_schema.SPIDER_WRAPPER_PROTOCOLS;
```

Create Federated Spider Table

```
CREATE SERVER hq_server
FOREIGN DATA WRAPPER mariadb
OPTIONS (
   HOST "192.0.2.2",
   PORT 5801,
   USER "spider_user",
   PASSWORD "password",
   DATABASE "hq_sales"
);

CREATE DATABASE spider_hq_sales;

CREATE TABLE spider_hq_sales.invoices (
   branch_id INT NOT NULL,
   invoice_id INT NOT NULL,
   customer_id INT,
   invoice_date DATETIME(6),
   invoice_total DECIMAL(13, 2),
   payment_method ENUM('NONE', 'CASH', 'WIRE_TRANSFER', 'CREDIT_CARD', 'GIFT_CARD'),
   PRIMARY KEY(branch_id, invoice_id)
) ENGINE=Spider

ODBC MariaDB Enterprise Spider Topology

Overview

In the ODBC MariaDB Enterprise Spider topology, a Spider Node contains one or more “virtual” Spider Tables. A Spider Table does not store data. When the Spider Table is queried in this topology, the Enterprise Spider storage engine uses an ODBC foreign data wrapper to read from and write to an ODBC Data Source.

Benefits

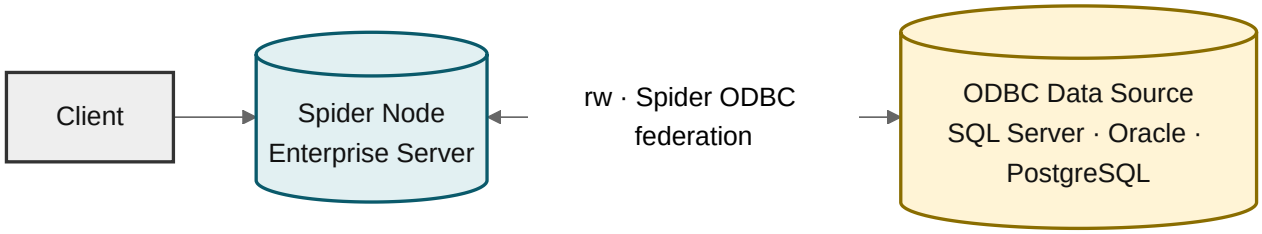
MariaDB Enterprise Spider:

- Supports a MariaDB foreign data wrapper. The MariaDB foreign data wrapper can be used to replace the older Federated and FederatedX storage engines.

- Supports an ODBC foreign data wrapper in MariaDB Enterprise Server 10.5 and later. The maturity can be confirmed by querying the information_schema.SPIDER_WRAPPER_PROTOCOLS table.

The Spider ODBC topology:

- Can be used to query ODBC Data Sources from the Spider Node using the ODBC foreign data wrapper.
- Can be used to join ODBC Data Sources with tables on the Spider Node using the ODBC foreign data wrapper.
- Can be used to migrate table data from ODBC Data Sources to the Spider Node using the ODBC foreign data wrapper.



In the Spider ODBC topology, a Spider Node uses an ODBC foreign data wrapper to read from and write to an external ODBC Data Source.

In the Spider ODBC topology, a Spider Node contains one or more “virtual” Spider Tables. A Spider Table does not store data. When the Spider Table is queried in this topology, the Enterprise Spider storage engine uses an ODBC foreign data wrapper to read from and write to an ODBC Data Source.

MariaDB Enterprise Spider implemented support for the ODBC foreign data wrapper in MariaDB Enterprise Server 10.5.

The maturity can be confirmed by querying the information_schema.SPIDER_WRAPPER_PROTOCOLS table.

The Spider ODBC topology consists of:

- One MariaDB Enterprise Server node is a Spider Node
- One ODBC Data Source stores data for Spider Tables

The Spider Node:

- Contains one or more Spider Tables
- Uses the Enterprise Spider storage engine plugin for Spider Tables
- Uses an ODBC foreign data wrapper to query the ODBC Data Source

The ODBC Data Source:

- Contains the Data for each Spider Table
- Can be a non-MariaDB database server, such as Microsoft SQL Server, Oracle, or PostgreSQL

Term Definitions

Term	Definition
Data Node	A Data Node is a MariaDB Enterprise Server node that contains one or more Data Tables.
Data Table	A Data Table stores data for a Spider Table. When a Spider Table is queried, the Enterprise Spider storage engine uses the MariaDB foreign data wrapper to read from and write to the Data Table on a Data Node. The Data Table must be created on the Data Node with the same structure as the Spider Table. The Data Table must use a non-Spider storage engine, such as InnoDB or ColumnStore.

Term	Definition
ODBC Data Source	An ODBC Data Source relies on an ODBC Driver and an ODBC Driver Manager to query an external data source.
ODBC Driver	An ODBC Driver is a library that integrates with a ODBC Driver Manager to query an external data source.
ODBC Driver Manager	An ODBC Driver Manager allows applications to use ODBC Drivers.
Spider Node	A Spider Node is a MariaDB Enterprise Server node that contains one or more Spider Tables.
Spider Table	A Spider Table is a virtual table that does not store data. When a Spider Table is queried, the Enterprise Spider storage engine uses foreign data wrappers to read from and write to Data Tables on Data Nodes or ODBC Data Sources.

Example Use Cases

Query Non-MariaDB Databases

The Spider ODBC topology can be used to query tables located on non-MariaDB databases:

- The non-MariaDB database is configured as an ODBC Data Source in the ODBC Driver Manager.
- The MariaDB Enterprise Server node that needs to query the ODBC Data Source is configured as a Spider Node.
- A Spider Table is created on the Spider Node that references the ODBC Data Source.
- On the Spider Node, the ODBC Data Source is queried by querying the Spider Table like the following:

```
SELECT * FROM spider_tab;
```

- Local tables can also be referenced in queries:

```
SELECT *
FROM spider_tab s
JOIN local_tab l
ON s.id=l.id;
```

Migrate Tables from Non-MariaDB Databases

- The Spider ODBC topology can be used to migrate tables from a non-MariaDB database to a MariaDB Enterprise Server node:
- The non-MariaDB database is configured as an ODBC Data Source in the ODBC Driver Manager.
- The MariaDB Enterprise Server node with the destination table is configured as a Spider Node.
- A Spider Table is created on the Spider Node that references the ODBC Data Source.
- On the Spider Node, the ODBC Data Source's data is migrated to the destination table by querying the Spider Table like the following:

```
INSERT INTO destination_tab
SELECT * FROM spider_tab;
```

Examples

Load Spider with Configuration File (ES 10.4+)

```
[mariadb]
...
plugin_load_add = "ha_spider"
```

Load Spider with INSTALL SONAME (ES 10.4+)

```
INSTALL SONAME "ha_spider";
```

View Foreign Data Wrappers (ES 10.5+)

```
SELECT * FROM information_schema.SPIDER_WRAPPER_PROTOCOLS;
```

Create ODBC Spider Table (with an Oracle remote server)

Follow the link under Operations for further information on the setup.

```
INSTALL SONAME 'ha_spider';
CREATE DATABASE spider_test;
USE spider_test;
CREATE OR REPLACE TABLE contacts (
    contact_id  BIGINT NOT NULL PRIMARY KEY,
    first_name  VARCHAR(255) NOT NULL,
    last_name   VARCHAR(255) NOT NULL,
    email       VARCHAR(255) NOT NULL,
    phone       VARCHAR(20),
    customer_id BIGINT
) ENGINE=SPIDER COMMENT='wrapper "odbc", dsn "ORARDS", table "CONTACTS"';
```

Sharded MariaDB Enterprise Spider Topology

Sharded MariaDB Enterprise Spider Topology

Overview

In the Sharded MariaDB Enterprise Spider topology, a Spider Node contains one or more “virtual” Spider Tables. A Spider Table does not store data. When a Spider Table is queried in this topology, the Enterprise Spider storage engine uses a MariaDB foreign data wrapper to read from and write to Data Tables on Data Nodes. The data for the Spider Table is partitioned among the Data Nodes using the regular partitioning syntax.

Benefits

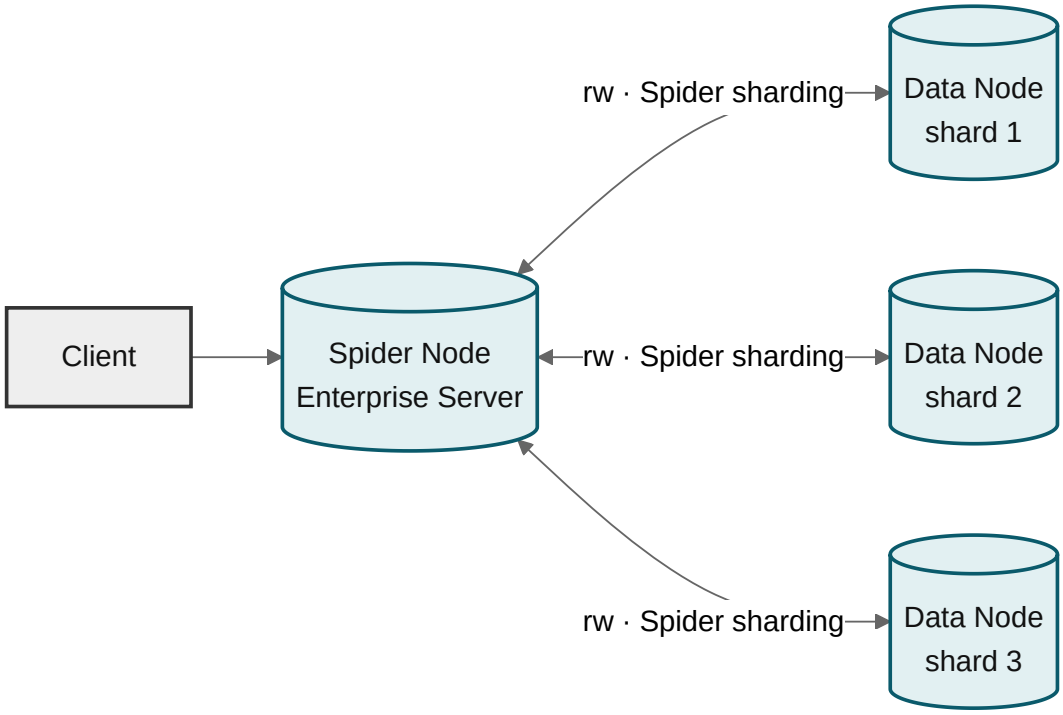
MariaDB Enterprise Spider:

- Supports a MariaDB foreign data wrapper. The MariaDB foreign data wrapper can be used to replace the older Federated and FederatedX storage engines.
- Supports an ODBC foreign data wrapper in MariaDB Enterprise Server 10.5 and later. The ODBC foreign data wrapper was backported to MariaDB Enterprise Server in a previous version. The ODBC foreign data wrapper is beta maturity. The maturity can be confirmed by querying the information_schema.SPIDER_WRAPPER_PROTOCOLS table.

The Spider Sharded topology:

- Can be used to consolidate multiple tables on multiple MariaDB Enterprise Server nodes into a single "virtual" table on the Spider Node using the MariaDB foreign data wrapper.
- Can be used to partition a large table across multiple MariaDB Enterprise Server nodes for horizontal scalability using the MariaDB foreign data wrapper.
- Defines Sharded Spider Tables with MariaDB Enterprise Server's regular partitioning syntax.

Sharded MariaDB Enterprise Spider Topology



Sharded Spider: a Spider Node distributes the partitions of a virtual sharded table across multiple Data Nodes (shards) via the Spider foreign data wrapper.

In the Spider Sharded topology, a Spider Node contains one or more "virtual" Spider Tables. A Spider Table does not store data. When a Spider Table is queried in this topology, the Enterprise Spider storage engine uses a MariaDB foreign data wrapper to read from and write to Data Tables on Data Nodes. The data for the Spider Table is partitioned among the Data Nodes using the regular partitioning syntax.

The Spider Sharded topology consists of:

- One MariaDB Enterprise Server node is a Spider Node
- One or more MariaDB Enterprise Server nodes are Data Nodes

The Spider Node:

- Contains one or more partitioned Spider Tables
- Uses the Enterprise Spider storage engine plugin for Spider Tables
- Uses a MariaDB foreign data wrapper to query the Data Tables on the Data Nodes

The Data Nodes:

- Contain Data Tables for one or more partitions of the Spider Table
- Use a non-Spider storage engine for each Data Table, such as InnoDB or ColumnStore

Term Definitions

Term	Definition
Data Node	A Data Node is a MariaDB Enterprise Server node that contains one or more Data Tables.
Data Table	A Data Table stores data for a Spider Table. When a Spider Table is queried, the Enterprise Spider storage engine uses the MariaDB foreign data wrapper to read from and write to the Data Table on a Data Node. The Data Table must be created on the Data Node with the same structure as the Spider Table. The Data Table must use a non-Spider storage engine, such as InnoDB or ColumnStore.
ODBC Data Source	An ODBC Data Source relies on an ODBC Driver and an ODBC Driver Manager to query an external data source.
ODBC Driver	An ODBC Driver is a library that integrates with a ODBC Driver Manager to query an external data source.
ODBC Driver Manager	An ODBC Driver Manager allows applications to use ODBC Drivers.
Spider Node	A Spider Node is a MariaDB Enterprise Server node that contains one or more Spider Tables.
Spider Table	A Spider Table is a virtual table that does not store data. When a Spider Table is queried, the Enterprise Spider storage engine uses foreign data wrappers to read from and write to Data Tables on Data Nodes or ODBC Data Sources.

Example Use Cases

Shard Big Tables

The Spider Sharded topology can be used to split table data into multiple shards stored on remote MariaDB Enterprise Server nodes for horizontal scalability:

- One MariaDB Enterprise Server node is configured as a Spider Node and accepts application queries.
- One or more MariaDB Enterprise Server nodes are configured as Data Nodes and store shards.

Consolidate Data for Multi-Location Businesses

The Spider Sharded topology can be used to implement a consolidated view of multiple remote databases:

- One MariaDB Enterprise Server is configured as a Spider Node and provides a consolidated view using Spider Tables.
- One or more MariaDB Enterprise Server nodes are configured as Data Nodes and contain the local data.

Examples

Load Spider with Configuration File

```
[mariadb]
...
plugin_load_add = "ha_spider"
```

Load Spider with INSTALL SONAME

```
INSTALL SONAME "ha_spider";
```

View Foreign Data Wrappers (ES 10.5+)

```
SELECT * FROM information_schema.SPIDER_WRAPPER_PROTOCOLS;
```

Create Sharded Spider Table

```
CREATE SERVER hq_server
FOREIGN DATA WRAPPER mariadb
OPTIONS (
   HOST "192.0.2.2",
   PORT 5801,
   USER "spider_user",
   PASSWORD "password",
   DATABASE "hq_sales"
);

CREATE SERVER eastern_server
FOREIGN DATA WRAPPER mariadb
OPTIONS (
   HOST "192.0.2.3",
   PORT 5801,
   USER "spider_user",
   PASSWORD "password",
   DATABASE "eastern_sales"
);

CREATE SERVER western_server
FOREIGN DATA WRAPPER mariadb
OPTIONS (
   HOST "192.0.2.4",
   PORT 5801,
   USER "spider_user",
   PASSWORD "password",
   DATABASE "western_sales"
);

CREATE DATABASE spider_sharded_sales;

CREATE TABLE spider_sharded_sales.invoices (
   branch_id INT NOT NULL,
   invoice_id INT NOT NULL,
   customer_id INT,
   invoice_date DATETIME(6),
   invoice_total DECIMAL(13, 2)
   payment_method ENUM('NONE', 'CASH', 'WIRE_TRANSFER', 'CREDIT_CARD', 'GIFT_CARD'),
   PRIMARY KEY(branch_id, invoice_id)
) ENGINE=Spider
PARTITION BY LIST(branch_id) (
   PARTITION hq_partition VALUES IN (1) COMMENT = 'server "hq_server", table "invoices"',
   PARTITION eastern_partition VALUES IN (2) COMMENT = 'server "eastern_server", table "invoices"',
   PARTITION western_partition VALUES IN (3) COMMENT = 'server "western_server", table "invoices"'
);
```

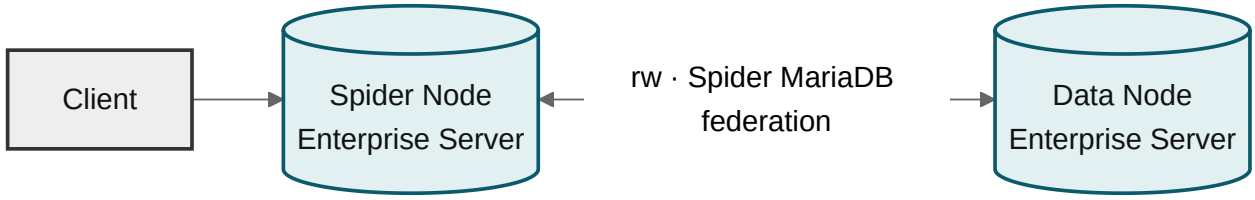
Spider Federated

Overview



In the Spider Federated topology, a Spider Node uses the MariaDB Spider federation to read from and write to a Data Table on a separate Data Node.

- Enterprise Server 10.4
- Enterprise Server 10.5
- Enterprise Server 10.6
- Enterprise Server 11.4

Read from and write to tables on remote ES nodes

- Spider Node uses Spider storage engine for Federated Spider Tables
- Federated Spider Table is a “virtual” table
- Spider uses MariaDB foreign data wrapper to query Data Table on Data Node
- Data Node uses non-Spider storage engine for Data Tables
- Supports transactions
- Enterprise Server 10.3+, Enterprise Spider

This procedure describes the deployment of the **Spider Federated topology** with MariaDB Enterprise Server

This procedure incrementally deploys MariaDB Enterprise Spider on an existing MariaDB Enterprise Server deployment.

In the Spider Federated topology, a Spider Node contains one or more “virtual” Spider Tables. A Spider Table does not store data. When a Spider Table is queried, the Enterprise Spider storage engine uses a MariaDB foreign data wrapper to read from and write to a Data Table on a Data Node.

This procedure has 3 steps, which are executed in sequence.

This page provides an overview of the topology, requirements, and deployment procedure.

The topology described is representative of basic product capabilities. MariaDB products can be deployed to form other topologies, leverage advanced product capabilities, or combine the capabilities of multiple topologies.

Prerequisites

If you have not yet deployed MariaDB Enterprise Server on the Spider Node and Data Node, first deploy a topology containing MariaDB Enterprise Server. Several topologies are documented.

Procedure Steps

Step	Description
Step 1	Install Enterprise Spider
Step 2	Configure Spider Node and Data Node
Step 3	Test Spider Federated Topology

Support

Customers can obtain support by submitting a support case.

Components

The following components are deployed during this procedure:

Component	Function
MariaDB Enterprise Server	Modern SQL RDBMS with high availability, pluggable storage engines, hot online backups, and audit logging.
MariaDB Enterprise Spider	Storage engine used by Spider Tables to read from and write to Data Tables using the MariaDB foreign data wrapper.

Term Definitions

Term	Definition
Data Node	A Data Node is a MariaDB Enterprise Server node that contains one or more Data Tables.
Data Table	A Data Table stores data for a Spider Table. When a Spider Table is queried, the Enterprise Spider storage engine uses the MariaDB foreign data wrapper to read from and write to the Data Table on a Data Node. The Data Table must be created on the Data Node with the same structure as the Spider Table. The Data Table must use a non-Spider storage engine, such as InnoDB or ColumnStore.
ODBC Data Source	An ODBC Data Source relies on an ODBC Driver and an ODBC Driver Manager to query an external data source.
ODBC Driver	An ODBC Driver is a library that integrates with a ODBC Driver Manager to query an external data source.
ODBC Driver Manager	An ODBC Driver Manager allows applications to use ODBC Drivers.
Spider Node	A Spider Node is a MariaDB Enterprise Server node that contains one or more Spider Tables.

Term	Definition
Spider Node	A Spider Table is a virtual table that does not store data. When a Spider Table is queried, the Enterprise Spider storage engine uses foreign data wrappers to read from and write to Data Tables on Data Nodes or ODBC Data Sources.

Topology

In the Spider Federated topology, a Spider Node contains one or more “virtual” Spider Tables. A Spider Table does not store data. When a Spider Table is queried, the Enterprise Spider storage engine uses a MariaDB foreign data wrapper to read from and write to a Data Table on a Data Node.

The Spider Federated topology consists of:

- One MariaDB Enterprise Server node is a Spider Node
- One MariaDB Enterprise Server node is a Data Node

The Spider Node:

- Contains one or more Spider Tables
- Uses the Enterprise Spider storage engine plugin for Spider Tables
- Uses a MariaDB foreign data wrapper to query the Data Table on the Data Node

The Data Node:

- Contains a Data Table for each Spider Table
- Uses a non-Spider storage engine for each Data Table, such as InnoDB or ColumnStore

For additional information, see “Spider Federated Topology Operations”.

Requirements

These requirements are for the Spider Federated topology when deployed with MariaDB Enterprise Server

- Node Count
- Operating Systems

Node Count

- One or more MariaDB Enterprise Server nodes must be deployed as Spider Nodes. The Spider Nodes contain Spider Tables.
- One or more MariaDB Enterprise Server nodes must be deployed as Data Nodes. The Data Nodes contain Data Tables.

Operating Systems

In alignment to the enterprise lifecycle, the Spider Federated topology with MariaDB Enterprise Server is provided for:

- AlmaLinux 8 (x86_64, ARM64)
- AlmaLinux 9 (x86_64, ARM64)
- Debian 11 (x86_64, ARM64)
- Debian 12 (x86_64, ARM64)
- Microsoft Windows (x86_64)
- Red Hat Enterprise Linux 8 (x86_64, ARM64)
- Red Hat Enterprise Linux 9 (x86_64, PPC64LE, ARM64)
- Red Hat UBI 8 (x86_64, ARM64)

- Rocky Linux 8 (x86_64, ARM64)
- Rocky Linux 9 (x86_64, ARM64)
- SUSE Linux Enterprise Server 15 (x86_64, ARM64)
- Ubuntu 20.04 LTS (x86_64, ARM64)
- Ubuntu 22.04 LTS (x86_64, ARM64)
- Ubuntu 24.04 LTS (x86_64, ARM64)

Next Step

Navigation in the procedure “Deploy Spider Federated Topology”:

Next: Step 1: Install Enterprise Spider

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 1: Install Enterprise Spider

Overview

This page details step 1 of the 3-step procedure “Deploy Spider Federated Topology”.

This step installs the Enterprise Spider storage engine plugin on the Spider Node.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Allow Interconnect

MariaDB Enterprise Spider depends on interconnect between the Spider Node and the Data Node. This may require adjustment to firewall and security settings.

Install Spider Package

The Enterprise Spider storage engine plugin is not installed with MariaDB Enterprise Server by default. An additional package must be installed.

Install via YUM (CentOS, RHEL)

On the Spider Node, install MariaDB Enterprise Spider:

```
$ sudo yum install MariaDB-spider-engine
```

Install via APT (Debian, Ubuntu)

On the Spider Node, install MariaDB Enterprise Spider:

```
$ sudo apt install mariadb-plugin-spider
```

Install via ZYpp (SLES)

On the Spider Node, install MariaDB Enterprise Spider:

```
$ sudo zypper install MariaDB-spider-engine
```

Load the Spider Plugin

The Enterprise Spider storage engine plugin must be loaded by MariaDB Enterprise Server.

On the Spider Node, use one of the following methods to configure MariaDB Enterprise Server to load the Enterprise Spider storage engine plugin:

Interface	Method	Benefits
Shell	Configuration File	• SQL access is not required • SUPER privilege is not required • Configuration file can be version controlled
SQL	INSTALL SONAME Statement	• Shell access is not required • File system privileges on configuration file are not required • Plugin is included in backup of mysql.plugin system table • Spider Node restart is not required

Load Spider with Configuration File

On the Spider Node, set the `plugin_load_add` option to `ha_spider` in a configuration file. This option configures MariaDB Enterprise Server to load the Enterprise Spider storage engine plugin. The Spider Node must be restarted to detect the configuration change.

1. Choose a configuration file for custom changes to system variables and options.

   It is not recommended to make custom changes to Enterprise Server's default configuration files, because your custom changes can be overwritten by other default configuration files that are loaded after.

   Ensure that your custom changes will be read last by creating a custom configuration file in one of the included directories. Configuration files in included directories are read in alphabetical order. Ensure that your custom configuration file is read last by using the z- prefix in the file name.

   Some example configuration file paths for different distributions are shown in the following table:

Distributions	Example configuration file path
• CentOS • RHEL • Rocky Linux • SLES	`/etc/my.cnf.d/z-custom-mariadb.cnf`
• Debian • Ubuntu	`/etc/mysql/mariadb.conf.d/z-custom-mariadb.cnf`

2. Set the `plugin_load_add` option in the configuration file.

   It must be set in a group that will be read by MariaDB Server, such as `[mariadb]` or `[server]`.

   For example:

```
[mariadb]
...
plugin_load_add = "ha_spider"
```

3. Restart MariaDB Enterprise Server:

```
$ sudo systemctl restart mariadb
```

Load Spider with INSTALL SONAME

On the Spider Node, execute the INSTALL SONAME statement with the library name `ha_spider`. The `INSTALL SONAME` statement configures MariaDB Enterprise Server to load the Enterprise Spider storage engine plugin. The `INSTALL SONAME` statement requires the SUPER privilege.

The `INSTALL SONAME` statement adds the Enterprise Spider storage engine to the mysql.plugin system table. When the Spider Node is restarted, MariaDB Enterprise Server reads the system table and reloads the plugin, so the statement only needs to be executed once.

1. Connect to the Spider Node using mariadb Client:

```
$ sudo mariadb
```

2. Use the INSTALL SONAME statement to install the Enterprise Spider storage engine plugin:

```
INSTALL SONAME "ha_spider";
```

Test Plugin Installation

On the Spider Node, confirm that the Enterprise Spider storage engine plugin is loaded by querying the information_schema.PLUGINS table:

```
SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM information_schema.PLUGINS
WHERE PLUGIN_LIBRARY LIKE "ha_spider%";

+--------------------------+---------------+
| PLUGIN_NAME              | PLUGIN_STATUS |
+--------------------------+---------------+
| SPIDER                   | ACTIVE        |
| SPIDER_ALLOC_MEM         | ACTIVE        |
| SPIDER_WRAPPER_PROTOCOLS | ACTIVE        |
+--------------------------+---------------+
```

When the Enterprise Spider storage engine is loaded, the `PLUGIN_NAME` column contains the value `SPIDER` and the `PLUGIN_STATUS` column contains the value `ACTIVE`.

Next Step

Navigation in the procedure “Deploy Spider Federated Topology”.

This page was step 1 of 3.

Next: Step 2: Configure Spider Node and Data Node

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 2: Configure Spider Node and Data Node

Overview

This page details step 2 of the 3-step procedure “Deploy Spider Federated Topology”.

This step configures the Spider Node and Data Node and creates the Spider Table and Data Table.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Create Spider User

The data node requires a user account that the Spider Node uses to connect.

On the Data Node, create the Spider user account for the Spider Node using the CREATE USER statement:

```
CREATE USER spider_user@192.0.2.1 IDENTIFIED BY "password";
```

Privileges will be granted to the user account in Grant Privileges on the Data Table.

Test Spider User

On the Spider Node, confirm that the Spider user account can connect to the Data Node using MariaDB Client:

```
$ mariadb --user spider_user --host 192.0.2.2 --password
```

Configure Connection Details

The Spider Node requires connection details for the Data Node.

On the Spider Node, create a server object to configure the connection details for the Data Node using the CREATE SERVER statement:

```
CREATE SERVER hq_server
FOREIGN DATA WRAPPER mariadb
OPTIONS (
   HOST "192.0.2.2",
   PORT 5801,
   USER "spider_user",
   PASSWORD "password",
   DATABASE "hq_sales"
);
```

The Data Node runs MariaDB Enterprise Server, so the `FOREIGN DATA WRAPPER` is set to `mariadb`.

Using a server object for connection details is optional. Alternatively, the connection details for the Data Node can be specified in the `COMMENT` table option of the CREATE TABLE statement when creating the Spider Table.

Create the Data Table

When queries read and write to a Spider Table, Spider reads and writes to the Data Table on the Data Node. The Data Table must be created on the Data Node with the same structure as the Spider Table.

If your Data Table already exists, grant privileges on the table to the Spider user.

On the Data Node, create the Data Table:

```
CREATE DATABASE hq_sales;

CREATE SEQUENCE hq_sales.invoice_seq;

CREATE TABLE hq_sales.invoices (
   branch_id INT NOT NULL DEFAULT (1) CHECK (branch_id=1),
   invoice_id INT NOT NULL DEFAULT (NEXT VALUE FOR hq_sales.invoice_seq),
   customer_id INT,
   invoice_date DATETIME(6),
   invoice_total DECIMAL(13, 2),
   payment_method ENUM('NONE', 'CASH', 'WIRE_TRANSFER', 'CREDIT_CARD', 'GIFT_CARD'),
   PRIMARY KEY(branch_id, invoice_id)
) ENGINE=InnoDB;

INSERT INTO hq_sales.invoices
   (customer_id, invoice_date, invoice_total, payment_method)
VALUES
   (1, '2020-05-10 12:35:10', 1087.23, 'CREDIT_CARD'),
   (2, '2020-05-10 14:17:32', 1508.57, 'WIRE_TRANSFER'),
   (3, '2020-05-10 14:25:16', 227.15, 'CASH');
```

The Spider Node reads and writes to the Data Table using the server and user account configured in "Configure Connection Details". The user account must have privileges on the tables.

Grant Privileges

The Spider Node connects to the Data Node with the user account configured in "Create Spider User".

On the Data Node, grant the Spider user sufficient privileges to operate on the Data Table:

```
GRANT ALL PRIVILEGES ON hq_sales.invoices TO 'spider_user'@'192.0.2.1';
```

Privileges for Spider BKA Mode

By default, the Spider user also requires the CREATE TEMPORARY TABLES privilege on the database containing the Data Table. The `CREATE TEMPORARY TABLES` privilege is required, because Spider uses temporary tables to optimize read queries when Spider BKA Mode is `1`.

Spider BKA Mode is configured using the following methods:

- The session value is configured by setting the spider_bka_mode system variable on the Spider Node. The default value is `-1`. When the session value is `-1`, the value for each Spider Table is used.
- The value for each Spider Table is configured by setting the `bka_mode` option in the `COMMENT` table option. When the `bka_mode` option is not set, the implicit value is `1`.

The default spider_bka_mode value is `-1`, and the implicit Spider Table value is `1`, so the default Spider BKA Mode is `1`.

On the Data Node, grant the Spider user the `CREATE TEMPORARY TABLES` privilege on the database:

```
GRANT CREATE TEMPORARY TABLES ON hq_sales.* TO 'spider_user'@'192.0.2.1';
```

Create the Spider Table

The Spider Table must be created on the Spider Node with the same structure as the Data Table.

On the Spider Node, create the Spider Table and reference the Data Node in the `COMMENT` table option:

```
CREATE DATABASE spider_hq_sales;

CREATE TABLE spider_hq_sales.invoices (
   branch_id INT NOT NULL,
   invoice_id INT NOT NULL,
   customer_id INT,
   invoice_date DATETIME(6),
   invoice_total DECIMAL(13, 2),
   payment_method ENUM('NONE', 'CASH', 'WIRE_TRANSFER', 'CREDIT_CARD', 'GIFT_CARD'),
   PRIMARY KEY(branch_id, invoice_id)
) ENGINE=Spider
COMMENT='server "hq_server", table "invoices"';
```

The `COMMENT` table option is used to configure the Data Node and the Data Table. Set the server option to the server object configured in "Configure Connection Details". Set the `table` option to the Data Table.

An alternative syntax is available. When you don't want to create a server object, the connection details for the Data Node can be specified in the `COMMENT` table option:

```
CREATE TABLE spider_hq_sales.invoices_alternate (
   branch_id INT NOT NULL,
   invoice_id INT NOT NULL,
   customer_id INT,
   invoice_date DATETIME(6),
   invoice_total DECIMAL(13, 2),
   payment_method ENUM('NONE', 'CASH', 'WIRE_TRANSFER', 'CREDIT_CARD', 'GIFT_CARD'),
   PRIMARY KEY(branch_id, invoice_id)
) ENGINE=Spider
COMMENT='table "invoices", host "192.0.2.2", port "5801", user "spider_user", password "user_password",
database "hq_sales"';
```

Next Step

Navigation in the procedure “Deploy Spider Federated Topology”:

This page was step 2 of 3.

Next: Step 3: Test Spider Federated Topology.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 3: Test Spider Federated Topology

Overview

This page details step 3 of the 3-step procedure “Deploy Spider Federated Topology”.

This step tests MariaDB Enterprise Spider.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Test Enterprise Server Service

Use Systemd to test whether the MariaDB Enterprise Server service is running.

This action is performed **on the Spider Node and Data Node**.

Check if the MariaDB Enterprise Server service is running by executing the following:

```
$ systemctl status mariadb
```

If the service is not running on any node, start the service by executing the following on that node:

```
$ sudo systemctl start mariadb
```

Test Local Client Connections

Use MariaDB Client to test the local connection to the Enterprise Server node.

This action is performed on the Spider Node and Data Node:

```
$ sudo mariadb
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 38
Server version: 11.4.5-3-MariaDB-Enterprise MariaDB Enterprise Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]>
```

The sudo command is used here to connect to the Enterprise Server node using the `root@localhost` user account, which authenticates using the `unix_socket` authentication plugin. Other user accounts can be used by specifying the `--user` and `--password` command-line options.

Test Data Node Client Connection

Use mariadb Client to test a client connection to the Data Node from the Spider Node using the Spider user.

This action is performed **on the Spider Node**:

```
$ mariadb \
   --host 192.0.2.2 \
   --user spider_user \
   --password
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 38
Server version: 11.4.5-3-MariaDB-Enterprise MariaDB Enterprise Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]>
```

The host and port of the Data Node can be provided using the `--host` and `--port` command-line options. The credentials for the Spider user can be provided using the `--user` and `--password` command-line options.

If the Spider user is unable to connect to the Data Node from the Spider Node, check the password for the Spider user account on the Data Node.

For additional information, see "Create Spider User".

Test Spider Storage Engine Plugin

Query the information_schema.PLUGINS table to confirm that the Enterprise Spider storage engine is loaded.

This action is performed **on the Spider Node**.

Execute the following query:

```
SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM information_schema.PLUGINS
WHERE PLUGIN_LIBRARY LIKE 'ha_spider%';

+--------------------------+---------------+
| PLUGIN_NAME              | PLUGIN_STATUS |
+--------------------------+---------------+
| SPIDER                   | ACTIVE        |
| SPIDER_ALLOC_MEM         | ACTIVE        |
| SPIDER_WRAPPER_PROTOCOLS | ACTIVE        |
+--------------------------+---------------+
```

The `PLUGIN_STATUS` column for each Spider-related plugin should contain `ACTIVE`.

For additional information, see "Load the Spider Plugin".

Test Write Operations

Write to the Spider Table using an INSERT statement to test write operations.

This action is performed **on the Spider Node**.

Execute the following query:

```
INSERT INTO spider_hq_sales.invoices
   (branch_id, invoice_id, customer_id, invoice_date, invoice_total, payment_method)
VALUES (1, 4, 1, '2021-03-10 12:45:10', 3045.73, 'CREDIT_CARD');
```

Test Read Operations

Read from the Spider Table using a SELECT statement to test read operations.

This action is performed **on the Spider Node**.

Execute the following query:

```
SELECT * FROM spider_hq_sales.invoices;

+-----------+------------+-------------+----------------------------+---------------+----------------+
| branch_id | invoice_id | customer_id | invoice_date               | invoice_total | payment_method |
+-----------+------------+-------------+----------------------------+---------------+----------------+
|         1 |          1 |           1 | 2020-05-10 12:35:10.000000 |       1087.23 | CREDIT_CARD    |
|         1 |          2 |           2 | 2020-05-10 14:17:32.000000 |       1508.57 | WIRE_TRANSFER  |
|         1 |          3 |           3 | 2020-05-10 14:25:16.000000 |        227.15 | CASH           |
|         1 |          4 |           1 | 2021-03-10 12:45:10.000000 |       3045.73 | CREDIT_CARD    |
+-----------+------------+-------------+----------------------------+---------------+----------------+
```

Next Step

Navigation in the procedure “Deploy Spider Federated Topology”.

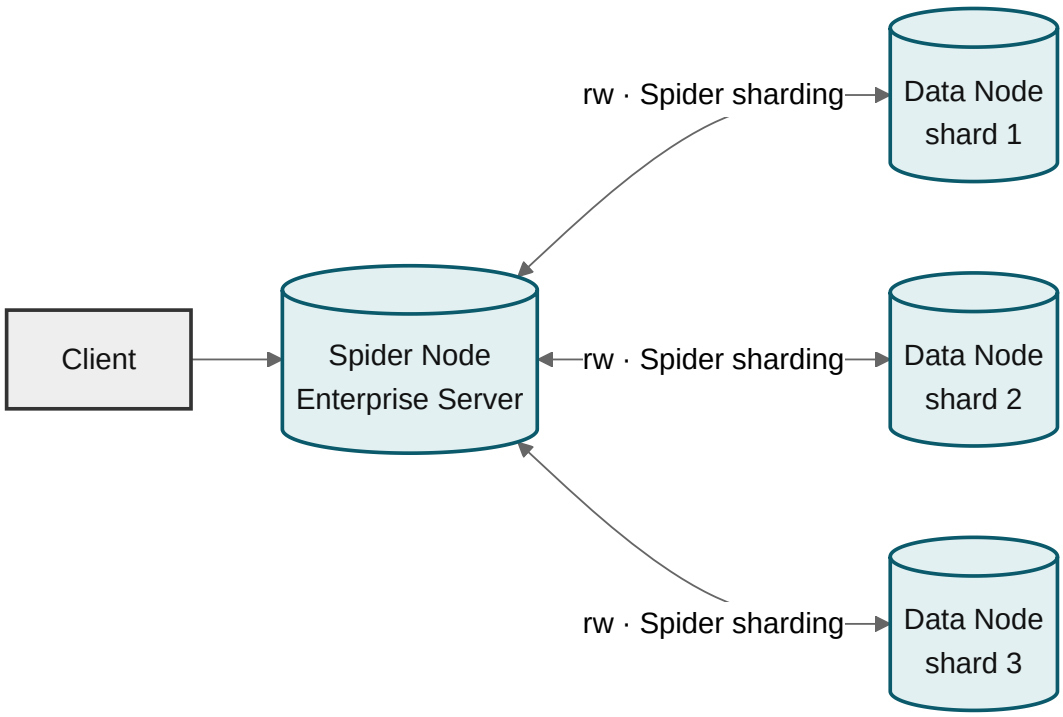
This page was step 3 of 3.

This procedure is complete.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Spider Sharded

Overview



Spider Sharded: a Spider Node distributes the partitions of a virtual sharded table across multiple Data Nodes (shards) via the Spider foreign data wrapper.

- Enterprise Server 10.4
- Enterprise Server 10.5
- Enterprise Server 10.6
- Enterprise Server 11.4

Shard tables for horizontal scalability

- Spider Node uses Spider storage engine for Sharded Spider Tables
- Sharded Spider Table is a partitioned “virtual” table
- Spider uses MariaDB foreign data wrapper to query Data Tables on Data Nodes for each partition
- Data Node uses non-Spider storage engine for Data Tables
- Supports transactions
- Enterprise Server 10.3+, Enterprise Spider

This procedure describes the deployment of the **Spider Sharded topology** with MariaDB Enterprise Server.

This procedure incrementally deploys MariaDB Enterprise Spider on an existing MariaDB Enterprise Server deployment.

In the Spider Sharded topology, a Spider Node contains one or more “virtual” Spider Tables. A Spider Table does not store data. When a Spider Table is queried in this topology, the Enterprise Spider storage engine uses a MariaDB foreign data wrapper to read from and write to Data Tables on Data Nodes. The data for the Spider Table is partitioned among the Data Nodes using the regular partitioning syntax.

This procedure has 3 steps, which are executed in sequence.

This page provides an overview of the topology, requirements, and deployment procedure.

The topology described is representative of basic product capabilities. MariaDB products can be deployed to form other topologies, leverage advanced product capabilities, or combine the capabilities of multiple topologies.

Prerequisites

If you have not yet deployed MariaDB Enterprise Server on the Spider Node and Data Nodes, first deploy a topology containing MariaDB Enterprise Server. Several topologies are documented.

Procedure Steps

Step	Description
Step 1	Install Enterprise Spider
Step 2	Configure Spider Node and Data Nodes
Step 3	Test Spider Sharded Topology

Support

Customers can obtain support by submitting a support case.

Components

The following components are deployed during this procedure:

Component	Function
MariaDB Enterprise Server	Modern SQL RDBMS with high availability, pluggable storage engines, hot online backups, and audit logging.
MariaDB Enterprise Spider	Storage engine used by Spider Tables to read from and write to Data Tables using the MariaDB foreign data wrapper.

Term Definitions

Term	Definition
Data Node	A Data Node is a MariaDB Enterprise Server node that contains one or more Data Tables.
Data Table	A Data Table stores data for a Spider Table. When a Spider Table is queried, the Enterprise Spider storage engine uses the MariaDB foreign data wrapper to read from and write to the Data Table on a Data Node. The Data Table must be created on the Data Node with the same structure as the Spider Table. The Data Table must use a non-Spider storage engine, such as InnoDB or ColumnStore.
ODBC Data Source	An ODBC Data Source relies on an ODBC Driver and an ODBC Driver Manager to query an external data source.
ODBC Driver	An ODBC Driver is a library that integrates with a ODBC Driver Manager to query an external data source.
ODBC Driver Manager	An ODBC Driver Manager allows applications to use ODBC Drivers.
Spider Node	A Spider Node is a MariaDB Enterprise Server node that contains one or more Spider Tables.
Spider Node	A Spider Table is a virtual table that does not store data. When a Spider Table is queried, the Enterprise Spider storage engine uses foreign data wrappers to read from and write to Data Tables on Data Nodes or ODBC Data Sources.

Topology

In the Spider Sharded topology, a Spider Node contains one or more “virtual” Spider Tables. A Spider Table does not store data. When a Spider Table is queried, the Enterprise Spider storage engine uses a MariaDB foreign data wrapper to read from and write to Data Tables on Data Nodes. The data for the Spider Table is partitioned among the Data Nodes using the regular partitioning syntax.

The Spider Sharded topology consists of:

- One MariaDB Enterprise Server node is a Spider Node
- One or more MariaDB Enterprise Server nodes are Data Nodes

The Spider Node:

- Contains one or more Spider Tables
- Uses the Enterprise Spider storage engine plugin for Spider Tables
- Uses a MariaDB foreign data wrapper to query the Data Tables on the Data Nodes

The Data Nodes:

- Contain Data Tables for one or more partitions of the Spider Table
- Uses a non-Spider storage engine for each Data Table, such as InnoDB or ColumnStore

For additional information, see “Spider Sharded Topology”.

Requirements

These requirements are for the Spider Sharded topology when deployed with MariaDB Enterprise Server

- Node Count

- Operating Systems

Node Count

- One or more MariaDB Enterprise Server nodes must be deployed as Spider Nodes. The Spider Nodes contain Spider Tables.
- One or more MariaDB Enterprise Server nodes must be deployed as Data Nodes. The Data Nodes contain Data Tables.

Operating Systems

In alignment to the enterprise lifecycle, the Spider Sharded topology with MariaDB Enterprise Server is provided for:

- AlmaLinux 8 (x86_64, ARM64)
- AlmaLinux 9 (x86_64, ARM64)
- Debian 11 (x86_64, ARM64)
- Debian 12 (x86_64, ARM64)
- Microsoft Windows (x86_64)
- Red Hat Enterprise Linux 8 (x86_64, ARM64)
- Red Hat Enterprise Linux 9 (x86_64, PPC64LE, ARM64)
- Red Hat UBI 8 (x86_64, ARM64)
- Rocky Linux 8 (x86_64, ARM64)
- Rocky Linux 9 (x86_64, ARM64)
- SUSE Linux Enterprise Server 15 (x86_64, ARM64)
- Ubuntu 20.04 LTS (x86_64, ARM64)
- Ubuntu 22.04 LTS (x86_64, ARM64)
- Ubuntu 24.04 LTS (x86_64, ARM64)

Next Step

Navigation in the procedure “Deploy Spider Sharded Topology”:

Next: Step 1: Install Enterprise Spider

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 1: Install Enterprise Spider

Overview

This page details step 1 of the 3-step procedure “Deploy Spider Sharded Topology”.

This step installs the Enterprise Spider storage engine plugin on the Spider Node.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Allow Interconnect

MariaDB Enterprise Spider depends on interconnect between the Spider Node and all Data Nodes. This may require adjustment to firewall and security settings.

Install Spider Package

The Enterprise Spider storage engine plugin is not installed with MariaDB Enterprise Server by default. An additional package must be installed.

Install via YUM (CentOS, RHEL)

On the Spider Node, install MariaDB Enterprise Spider:

```
$ sudo yum install MariaDB-spider-engine
```

Install via APT (Debian, Ubuntu)

On the Spider Node, install MariaDB Enterprise Spider:

```
$ sudo apt install mariadb-plugin-spider
```

Install via ZYpp (SLES)

On the Spider Node, install MariaDB Enterprise Spider:

```
$ sudo zypper install MariaDB-spider-engine
```

Load the Spider Plugin

The Enterprise Spider storage engine plugin must be loaded by MariaDB Enterprise Server

On the Spider Node, use one of the following methods to configure MariaDB Enterprise Server to load the Enterprise Spider storage engine plugin:

Interface	Method	Benefits
Shell	Configuration File	• SQL access is not required • SUPER privilege is not required • Configuration file can be version controlled
SQL	INSTALL SONAME Statement	• Shell access is not required • File system privileges on configuration file are not required • Plugin is included in backup of mysql.plugin system table • Spider Node restart is not required

Load Spider with Configuration File

On the Spider Node, set the `plugin_load_add` option to `ha_spider` in a configuration file. The plugin_load_add option configures MariaDB Enterprise Server to load the Enterprise Spider storage engine plugin. The Spider Node must be restarted to detect the configuration change.

1. Choose a configuration file for custom changes to system variables and options.
   It is not recommended to make custom changes to Enterprise Server's default configuration files, because your custom changes can be overwritten by other default configuration files that are loaded after.

   Ensure that your custom changes will be read last by creating a custom configuration file in one of the included directories. Configuration files in included directories are read in alphabetical order. Ensure that your custom configuration file is read last by using the z- prefix in the file name.

   Some example configuration file paths for different distributions are shown in the following table:

Distributions	Example configuration file path
• CentOS • RHEL • Rocky Linux • SLES	`/etc/my.cnf.d/z-custom-mariadb.cnf`
• Debian • Ubuntu	`/etc/mysql/mariadb.conf.d/z-custom-mariadb.cnf`

2. Set the plugin_load_add option in the configuration file.

   It must be set in a group that will be read by MariaDB Server, such as `[mariadb]` or `[server]`.

   For example:

```
[mariadb]
...
plugin_load_add = "ha_spider"
```

3. Restart MariaDB Enterprise Server:

```
$ sudo systemctl restart mariadb
```

Load Spider with INSTALL SONAME

On the Spider Node, execute the INSTALL SONAME statement with the library name `ha_spider`. The `INSTALL SONAME` statement configures MariaDB Enterprise Server to load the Enterprise Spider storage engine plugin. The `INSTALL SONAME` statement requires the SUPER privilege.

The `INSTALL SONAME` statement adds the Enterprise Spider storage engine to the mysql.plugin system table. When the Spider Node is restarted, MariaDB Enterprise Server reads the system table and reloads the plugin, so the statement only needs to be executed once.

1. Connect to the Spider Node using MariaDB Client:

```
$ sudo mariadb
```

2. Use the INSTALL SONAME statement to install the Enterprise Spider storage engine plugin:

```
INSTALL SONAME "ha_spider";
```

Test Plugin Installation

On the Spider Node, confirm that the Enterprise Spider storage engine plugin is loaded by querying the information_schema.PLUGINS table:

```
SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM information_schema.PLUGINS
WHERE PLUGIN_LIBRARY LIKE "ha_spider%";

+--------------------------+---------------+
| PLUGIN_NAME              | PLUGIN_STATUS |
+--------------------------+---------------+
| SPIDER                   | ACTIVE        |
| SPIDER_ALLOC_MEM         | ACTIVE        |
| SPIDER_WRAPPER_PROTOCOLS | ACTIVE        |
+--------------------------+---------------+
```

When the Enterprise Spider storage engine is loaded, the `PLUGIN_NAME` column contains the value `SPIDER` and the `PLUGIN_STATUS` column contains the value `ACTIVE`.

Next Step

Navigation in the procedure “Deploy Spider Sharded Topology”:

This page was step 1 of 3.

Next: Step 2: Configure Spider Node and Data Nodes.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 2: Configure Spider Node and Data Nodes

Overview

This page details step 2 of the 3-step procedure “Deploy Spider Sharded Topology”.

This step configures the Spider Node and Data Nodes and creates the Spider Table and Data Tables.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Create Spider User

The data node requires a user account that the Spider Node uses to connect.

On each Data Node, create the Spider user account for the Spider Node using the CREATE USER statement:

```
CREATE USER spider_user@192.0.2.1 IDENTIFIED BY "password";
```

Privileges will be granted to the user account in Grant Privileges on the Data Table.

Test Spider User

On the Spider Node, confirm that the Spider user account can connect to the Data Node using MariaDB Client:

```
$ mariadb --user spider_user --host 192.0.2.2 --password
```

Configure Connection Details

The Spider Node requires connection details for each Data Node.

On the Spider Node, create a server object to configure the connection details for each Data Node using the CREATE SERVER statement:

1. Create a Server object to configure the connection details for the Data Node at the headquarters branch:\

```
CREATE SERVER hq_server
FOREIGN DATA WRAPPER mariadb
OPTIONS (
   HOST "192.0.2.2",
   PORT 5801,
   USER "spider_user",
   PASSWORD "password",
   DATABASE "hq_sales"
);
```

2. Create a server object to configure the connection details for the Data Node at the eastern branch:\

```
CREATE SERVER eastern_server
FOREIGN DATA WRAPPER mariadb
OPTIONS (
   HOST "192.0.2.3",
   PORT 5801,
   USER "spider_user",
   PASSWORD "password",
   DATABASE "eastern_sales"
);
```

3. Create a server object to configure the connection details for the Data Node at the western branch:

```
CREATE SERVER western_server
FOREIGN DATA WRAPPER mariadb
OPTIONS (
   HOST "192.0.2.4",
   PORT 5801,
   USER "spider_user",
   PASSWORD "password",
   DATABASE "western_sales"
);
```

The Data Node runs MariaDB Enterprise Server, so the `FOREIGN DATA WRAPPER` is set to `mariadb`.

Using a server object for connection details is optional. Alternatively, the connection details for the Data Node can be specified in the `COMMENT` table option of the CREATE TABLE statement when creating the Spider Table.

Create the Data Tables

When queries read and write to a Spider Table, Spider reads and writes to the Data Tables for each partition on the on the Data Nodes. The Data Tables must be created on the Data Nodes with the same structure as the Spider Table.

If your Data Tables already exist, grant privileges on the tables to the Spider user.

On each Data Node, create the Data Tables:

1. On the Data Node for the headquarters server, create a database and table and add sample data:

```
CREATE DATABASE hq_sales;

CREATE SEQUENCE hq_sales.invoice_seq;

CREATE TABLE hq_sales.invoices (
   branch_id INT NOT NULL DEFAULT (1) CHECK (branch_id=1),
   invoice_id INT NOT NULL DEFAULT (NEXT VALUE FOR hq_sales.invoice_seq),
   customer_id INT,
   invoice_date DATETIME(6),
   invoice_total DECIMAL(13, 2),
   payment_method ENUM('NONE', 'CASH', 'WIRE_TRANSFER', 'CREDIT_CARD', 'GIFT_CARD'),
   PRIMARY KEY(branch_id, invoice_id)
) ENGINE=InnoDB;

INSERT INTO hq_sales.invoices
   (customer_id, invoice_date, invoice_total, payment_method)
VALUES
   (1, '2020-05-10 12:35:10', 1087.23, 'CREDIT_CARD'),
   (2, '2020-05-10 14:17:32', 1508.57, 'WIRE_TRANSFER'),
   (3, '2020-05-10 14:25:16', 227.15, 'CASH');
```

The Spider Node reads and writes to the Data Table using the server and user account configured in “Configure Connection Details”. The user account must have privileges on the tables.

2. On the Data Node for the eastern branch of the business, create a database and table and add sample data:\\

```
CREATE DATABASE eastern_sales;

CREATE SEQUENCE eastern_sales.invoice_seq;

CREATE TABLE eastern_sales.invoices (
   branch_id INT NOT NULL DEFAULT (2) CHECK (branch_id=2),
   invoice_id INT NOT NULL DEFAULT (NEXT VALUE FOR eastern_sales.invoice_seq),
   customer_id INT,
   invoice_date DATETIME(6),
   invoice_total DECIMAL(13, 2),
   payment_method ENUM('NONE', 'CASH', 'WIRE_TRANSFER', 'CREDIT_CARD', 'GIFT_CARD'),
   PRIMARY KEY(branch_id, invoice_id)
) ENGINE=InnoDB;

INSERT INTO eastern_sales.invoices
   (customer_id, invoice_date, invoice_total, payment_method)
VALUES
   (2, '2020-05-10 12:31:00', 1351.04, 'CREDIT_CARD'),
   (2, '2020-05-10 12:45:27', 162.11, 'WIRE_TRANSFER'),
   (4, '2020-05-10 13:11:23', 350.00, 'CASH');
```

   The Spider Node reads and writes to the Data Table using the server and user account configured in "Configure Connection Details". The user account must have privileges on the tables.\

3. On the Data Node for the western branch of the business, create a database and table and add sample data:\\

```
CREATE DATABASE western_sales;

CREATE SEQUENCE western_sales.invoice_seq;

CREATE TABLE western_sales.invoices (
   branch_id INT NOT NULL DEFAULT (3) CHECK (branch_id=3),
   invoice_id INT NOT NULL DEFAULT (NEXT VALUE FOR western_sales.invoice_seq),
   customer_id INT,
   invoice_date DATETIME(6),
   invoice_total DECIMAL(13, 2),
   payment_method ENUM('NONE', 'CASH', 'WIRE_TRANSFER', 'CREDIT_CARD', 'GIFT_CARD'),
   PRIMARY KEY(branch_id, invoice_id)
) ENGINE=InnoDB;

INSERT INTO western_sales.invoices
   (customer_id, invoice_date, invoice_total, payment_method)
VALUES
   (5, '2020-05-10 12:31:00', 111.50, 'CREDIT_CARD'),
   (8, '2020-05-10 12:45:27', 1509.23, 'WIRE_TRANSFER'),
   (3, '2020-05-10 13:11:23', 3301.66, 'CASH');
```

   The Spider Node reads and writes to the Data Table using the server and user account configured in "Configure Connection Details". The user account must have privileges on the tables.\

Grant Privileges

The Spider Node connects to the Data Nodes with the user account configured in "Create Spider User".

On each Data Node, grant the Spider user sufficient privileges to operate on the Data Table:

```
GRANT ALL PRIVILEGES ON hq_sales.invoices TO 'spider_user'@'192.0.2.1';
```

Privileges for Spider BKA Mode

By default, the Spider user also requires the `CREATE TEMPORARY TABLES` privilege on the database containing the Data Table. The `CREATE TEMPORARY TABLES` privilege is required, because Spider uses temporary tables to optimize read queries when Spider BKA Mode is `1`.

Spider BKA Mode is configured using the following methods:

- The session value is configured by setting the spider_bka_mode system variable on the Spider Node. The default value is `-1`. When the session value is `-1`, the value for each Spider Table is used.
- The value for each Spider Table is configured by setting the `bka_mode` option in the `COMMENT` table option. When the `bka_mode` option is not set, the implicit value is 1.

The default spider_bka_mode value is `-1`, and the implicit Spider Table value is `1`, so the default Spider BKA Mode is `1`.

On the Data Node, grant the Spider user the `CREATE TEMPORARY TABLES` privilege on the database:

```
GRANT CREATE TEMPORARY TABLES ON hq_sales.* TO 'spider_user'@'192.0.2.1';
```

Create the Spider Table

The Spider Table must be created on the Spider Node with the same structure as the Data Tables. The Spider Table must have a partition for each Data Table.

On the Spider Node, create the Spider Table and reference the Data Node in the `COMMENT` table option:

```
CREATE DATABASE spider_sharded_sales;

CREATE TABLE spider_sharded_sales.invoices (
   branch_id INT NOT NULL,
   invoice_id INT NOT NULL,
   customer_id INT,
   invoice_date DATETIME(6),
   invoice_total DECIMAL(13, 2),
   payment_method ENUM('NONE', 'CASH', 'WIRE_TRANSFER', 'CREDIT_CARD', 'GIFT_CARD'),
   PRIMARY KEY(branch_id, invoice_id)
) ENGINE=Spider
PARTITION BY LIST(branch_id) (
   PARTITION hq_partition VALUES IN (1) COMMENT = 'server "hq_server", table "invoices"',
   PARTITION eastern_partition VALUES IN (2) COMMENT = 'server "eastern_server", table "invoices"',
   PARTITION western_partition VALUES IN (3) COMMENT = 'server "western_server", table "invoices"'
);
```

The `COMMENT` partition option is used to configure the Data Node and the Data Table for each partition. Set the server option to the server object for the partition configured in "Configure Connection Details". Set the `table` option to the Data Table for the partition.

An alternative syntax is available. When you don't want to create a server object, the connection details for the Data Nodes can be specified in the `COMMENT` partition option:

```
CREATE TABLE spider_hq_sales.invoices_alternate (
   branch_id INT NOT NULL,
   invoice_id INT NOT NULL,
   customer_id INT,
   invoice_date DATETIME(6),
   invoice_total DECIMAL(13, 2),
   payment_method ENUM('NONE', 'CASH', 'WIRE_TRANSFER', 'CREDIT_CARD', 'GIFT_CARD'),
   PRIMARY KEY(branch_id, invoice_id)
) ENGINE=Spider
COMMENT='table "invoices", host "192.0.2.2", port "5801", user "spider_user", password "user_password",
database "hq_sales"';
```

Next Step

Navigation in the procedure “Deploy Spider Sharded Topology”:

This page was **step 2 of 3**.

Next: Step 3: Test Spider Sharded Topology.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Step 3: Test Spider Sharded Topology

Overview

This page details step 3 of the 3-step procedure “Deploy Spider Sharded Topology”.

This step tests MariaDB Enterprise Spider.

Interactive commands are detailed. Alternatively, the described operations can be performed using automation.

Test Enterprise Server Service

Use Systemd to test whether the MariaDB Enterprise Server service is running.

This action is performed **on the Spider Node and each Data Node**.

Check if the MariaDB Enterprise Server service is running by executing the following:

```
$ systemctl status mariadb
```

If the service is not running on any node, start the service by executing the following on that node:

```
$ sudo systemctl start mariadb
```

Test Local Client Connections

Use mariadb Client to test the local connection to the Enterprise Server node.

This action is performed **on the Spider Node and each Data Node**:

```
$ sudo mariadb
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 38
Server version: 11.4.5-3-MariaDB-Enterprise MariaDB Enterprise Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]>
```

The `sudo` command is used here to connect to the Enterprise Server node using the `root@localhost` user account, which authenticates using the `unix_socket` authentication plugin. Other user accounts can be used by specifying the `--user` and `--password` command-line options.

Test Data Node Client Connection

Use mariadb Client to test a client connection to the Data Node from the Spider Node using the Spider user.

This action is performed **on the Spider Node**:

```
$ mariadb \
   --host 192.0.2.2 \
   --user spider_user \
   --password
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 38
Server version: 11.4.5-3-MariaDB-Enterprise MariaDB Enterprise Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]>
```

The host and port of the Data Node can be provided using the `--host` and `--port` command-line options. The credentials for the Spider user can be provided using the `--user` and `--password` command-line options.

If the Spider user is unable to connect to the Data Node from the Spider Node, check the password for the Spider user account on the Data Node.

For additional information, see "Create Spider User".

Test Spider Storage Engine Plugin

Query the `information_schema.PLUGINS` table to confirm that the Enterprise Spider storage engine is loaded.

This action is performed **on the Spider Node**.

Execute the following query:

```
SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM information_schema.PLUGINS
WHERE PLUGIN_LIBRARY LIKE 'ha_spider%';

+--------------------------+---------------+
| PLUGIN_NAME              | PLUGIN_STATUS |
+--------------------------+---------------+
| SPIDER                   | ACTIVE        |
| SPIDER_ALLOC_MEM         | ACTIVE        |
| SPIDER_WRAPPER_PROTOCOLS | ACTIVE        |
+--------------------------+---------------+
```

The `PLUGIN_STATUS` column for each Spider-related plugin should contain `ACTIVE`.

For additional information, see "Load the Spider Plugin".

Test Write Operations

Write to the Spider Table using an INSERT statement to test write operations.

This action is performed **on the Spider Node**.

Execute the following query:

```
INSERT INTO spider_hq_sales.invoices
   (branch_id, invoice_id, customer_id, invoice_date, invoice_total, payment_method)
VALUES (1, 4, 1, '2021-03-10 12:45:10', 3045.73, 'CREDIT_CARD');
```

Test Read Operations

Read from the Spider Table using a SELECT statement to test read operations.

This action is performed **on the Spider Node**.

Execute the following query:

```
SELECT * FROM spider_sharded_sales.invoices;
```

```
+-----------+------------+-------------+----------------------------+---------------+----------------+
| branch_id | invoice_id | customer_id | invoice_date               | invoice_total | payment_method |
+-----------+------------+-------------+----------------------------+---------------+----------------+
|         1 |          1 |           1 | 2020-05-10 12:35:10.000000 |       1087.23 | CREDIT_CARD    |
|         1 |          2 |           2 | 2020-05-10 14:17:32.000000 |       1508.57 | WIRE_TRANSFER  |
|         1 |          3 |           3 | 2020-05-10 14:25:16.000000 |        227.15 | CASH           |
|         1 |          4 |           1 | 2021-03-10 12:45:10.000000 |       3045.73 | CREDIT_CARD    |
|         2 |          1 |           2 | 2020-05-10 12:31:00.000000 |       1351.04 | CREDIT_CARD    |
|         2 |          2 |           2 | 2020-05-10 12:45:27.000000 |        162.11 | WIRE_TRANSFER  |
|         2 |          3 |           4 | 2020-05-10 13:11:23.000000 |        350.00 | CASH           |
|         3 |          1 |           5 | 2020-05-10 12:31:00.000000 |        111.50 | CREDIT_CARD    |
|         3 |          2 |           8 | 2020-05-10 12:45:27.000000 |       1509.23 | WIRE_TRANSFER  |
|         3 |          3 |           3 | 2020-05-10 13:11:23.000000 |       3301.66 | CASH           |
+-----------+------------+-------------+----------------------------+---------------+----------------+
```

Test Sharding

Use the EXPLAIN PARTITIONS statement with a SELECT statement to determine which shards Spider will read for the query.

This action is performed **on the Spider Node**.

Execute the following query:

```
EXPLAIN PARTITIONS
SELECT * FROM spider_sharded_sales.invoices
WHERE customer_id = 4;
```

```
+------+-------------+----------+-------------------------------------------------+------+-------------
-+------+---------+------+------+---------------------------------+
| id   | select_type | table    | partitions                                      | type | possible_keys
| key  | key_len | ref  | rows | Extra                           |
+------+-------------+----------+-------------------------------------------------+------+-------------
-+------+---------+------+------+---------------------------------+
|    1 | SIMPLE      | invoices | hq_partition,eastern_partition,western_partition | ALL  | NULL
| NULL | NULL    | NULL | 9    | Using where with pushed condition |
+------+-------------+----------+-------------------------------------------------+------+-------------
-+------+---------+------+------+---------------------------------+
```

The specific shards read by the query are listed in the `partitions` column. If partition pruning does not eliminate unnecessary shards for a query with a restrictive filter, then check the partition definitions.

Next Step

Server Constraints

See Server Constraints Overview.

Provides a high-level overview of how MariaDB Server enforces data integrity through various architectural constraint types.

See AUTO_INCREMENT Constraints.

Explains the limitations and behavior of `AUTO_INCREMENT` columns, including how they handle maximum values and gaps in sequences.

See FOREIGN KEY Constraints.

Details the requirements and limitations for defining foreign keys to ensure referential integrity between tables.

See NOT NULL Constraints.

Describes how `NOT NULL` constraints prevent `NULL` values from being stored in specific columns.

See PRIMARY KEY Constraints.

Outlines the rules for primary keys, which uniquely identify each record in a table and cannot contain `NULL` values.

See UNIQUE Constraints.

Explains the specific implementation and considerations for unique constraints when using MariaDB Enterprise Server.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Server Constraints Overview

MariaDB Enterprise Server provides DDL (Data Definition Language) syntax to `create, alter, or drop` constraints.

In the context of `ISO 9075-2:2016`, this page uses “DDL (Data Definition Language)” to refer to SQL statements in the standard’s “SQL-schema statements” group.

AUTO_INCREMENT Constraints

To define an `AUTO_INCREMENT` column, select an integer data type to accommodate the range of anticipated values. Common choices include `INT`, `BIGINT`, `TINYINT`, `SMALLINT`, and `MEDIUMINT`, depending on size requirements. Ensure the chosen type provides sufficient capacity to avoid overflow while optimizing storage efficiency.

Overview

MariaDB Enterprise Server supports `AUTO_INCREMENT` constraints:

- A column with an `AUTO_INCREMENT` constraint can act as a table’s primary key when a natural primary key is not available
- Generated values for auto-increment columns are guaranteed to be unique and monotonically increasing
- Auto-increment columns provide compatibility with schemas designed for MariaDB Enterprise Server and MySQL

Alternatively, MariaDB Enterprise Server can use sequences as the primary key instead of columns with `AUTO_INCREMENT` constraints. Sequences are compliant with the SQL standard, while `AUTO_INCREMENT` constraints are not, so sequences are the better option for applications that require standard-compliant features.

Choosing a Data Type for an `AUTO_INCREMENT` Column

When designing a schema, `AUTO_INCREMENT` columns should use integer data types. The following types can be used:

Data Type	Signed Range	Unsigned Range
TINYINT	-128 - 127	0 - 255
SMALLINT	-32768 - 32767	0 - 65535
MEDIUMINT	-8388608 - 8388607	0 - 16777215
INT	-2147483648 - 2147483647	0 - 4294967295
BIGINT	-9223372036854775808 - 9223372036854775807	0 - 18446744073709551615

To determine which type to use, consider the following points:

1. Do you want to be able to manually insert negative values? If not, then specify the UNSIGNED attribute for the column.

InnoDB can't generate negative `AUTO_INCREMENT` values, so it is only beneficial to use a signed integer column if you want the option to manually insert negative values, which would bypass the `AUTO_INCREMENT` handling.

2. How large will your table grow?

If your `AUTO_INCREMENT` column is being used as the table's primary key, then the maximum value for the chosen data type should be considered the maximum number of rows that can fit in the table:

Data Type	Signed Range	Unsigned Range
TINYINT	127	255
SMALLINT	32767	65535
MEDIUMINT	8388607	16777215
INT	2147483647	4294967295
BIGINT	9223372036854775807	18446744073709551615

If you want to give your table the most room to grow, then it would be best to choose BIGINT UNSIGNED.

Creating an InnoDB Table with an AUTO_INCREMENT Column

Let's create an InnoDB table with an AUTO_INCREMENT column after confirming that the default storage engine is InnoDB:

1. Connect to the server using MariaDB Client:

```
$ mariadb --user=root
```

2. Confirm that the default storage engine is InnoDB by checking the default_storage_engine system variable using the SHOW SESSION VARIABLES statement:

```
SHOW SESSION VARIABLES
   LIKE 'default_storage_engine';
```

```
+------------------------+--------+
| Variable_name          | Value  |
+------------------------+--------+
| default_storage_engine | InnoDB |
+------------------------+--------+
```

3. If the database does not exist, then create the database for the table using the CREATE DATABASE statement:

```
CREATE DATABASE hq_sales;
```

4. Create the table using the CREATE TABLE statement:

```
CREATE TABLE hq_sales.invoices (
   invoice_id BIGINT UNSIGNED AUTO_INCREMENT NOT NULL,
   branch_id INT NOT NULL,
   customer_id INT,
   invoice_date DATETIME(6),
   invoice_total DECIMAL(13, 2),
   payment_method ENUM('NONE', 'CASH', 'WIRE_TRANSFER', 'CREDIT_CARD', 'GIFT_CARD'),
   PRIMARY KEY(invoice_id)
);
```

Inserting a Row with an AUTO_INCREMENT Column

If a column is specified as `AUTO_INCREMENT`, then its value will be automatically generated. There are multiple ways to insert rows with these automatically generated values.

Omitting the Column

If the column is not specified, then InnoDB will automatically generate the value.

Let's insert a row into the table created in the Creating an InnoDB Table with an AUTO_INCREMENT Column section:

1. Connect to the server using MariaDB Client:

```
$ mariadb --user=root
```

2. Insert a row with the INSERT statement, but do not specify the `AUTO_INCREMENT` column:

```
INSERT INTO hq_sales.invoices
   (branch_id, customer_id, invoice_date, invoice_total, payment_method)
VALUES
   (1, 1, '2020-05-10 12:35:10', 1087.23, 'CREDIT_CARD');
```

3. Select the same row with the SELECT statement to confirm that a value was automatically generated:

```
SELECT invoice_id
FROM hq_sales.invoices
WHERE branch_id = 1
AND customer_id = 1
AND invoice_date = '2020-05-10 12:35:10';
```

```
+------------+
| invoice_id |
+------------+
|          1 |
+------------+
```

Specifying the Column's Value as 0

If the column's value is specified as 0, then InnoDB will automatically generate the value if the sql_mode system variable does not contain `NO_AUTO_VALUE_ON_ZERO`.

Let's insert a row into the table created in the Creating an InnoDB Table with an AUTO_INCREMENT Column section:

1. Connect to the server using MariaDB Client:

```
$ mariadb --user=root
```

2. Confirm that the session's value of the sql_mode system variable does not contain NO_AUTO_VALUE_ON_ZERO with the SHOW SESSION VARIABLES statement:

```
SHOW SESSION VARIABLES
   LIKE 'sql_mode';
```

```
+---------------+-----------------------------------------------------------------------------------------------
---+
| Variable_name | Value
|
+---------------+-----------------------------------------------------------------------------------------------
---+
| sql_mode      |
STRICT_TRANS_TABLES,ERROR_FOR_DIVISION_BY_ZERO,NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION |
+---------------+-----------------------------------------------------------------------------------------------
---+
```

3. Insert a row with the INSERT statement, and specify the `AUTO_INCREMENT` column's value as 0:

```
INSERT INTO hq_sales.invoices
   (invoice_id, branch_id, customer_id, invoice_date, invoice_total, payment_method)
VALUES
   (0, 1, 2, '2020-05-10 14:17:32', 1508.57, 'WIRE_TRANSFER');
```

4. Select the same row with the SELECT statement to confirm that a value was automatically generated:

```
SELECT invoice_id
FROM hq_sales.invoices
WHERE branch_id = 1
AND customer_id = 2
AND invoice_date = '2020-05-10 14:17:32';
```

```
+------------+
| invoice_id |
+------------+
|          2 |
+------------+
```

Specifying the Column's Value as NULL

If the column's value is specified as NULL, then InnoDB will automatically generate the value if the column is defined as NOT NULL.

Let's insert a row into the table created in the Creating an InnoDB Table with an AUTO_INCREMENT Column section:

1. Connect to the server using MariaDB Client:

```
$ mariadb --user=root
```

2. Insert a row with the INSERT statement, and specify the `AUTO_INCREMENT` column's value as NULL:

```
INSERT INTO hq_sales.invoices
   (invoice_id, branch_id, customer_id, invoice_date, invoice_total, payment_method)
VALUES
   (NULL, 1, 3, '2020-05-10 14:25:16', 227.15, 'CASH');
```

3. Select the same row with the SELECT statement to confirm that a value was automatically generated:

```
SELECT invoice_id
FROM hq_sales.invoices
WHERE branch_id = 1
AND customer_id = 3
AND invoice_date = '2020-05-10 14:25:16';
```

```
+------------+
| invoice_id |
+------------+
|          3 |
+------------+
```

Getting the Last Inserted AUTO_INCREMENT Value

After InnoDB inserts an automatically generated value into an `AUTO_INCREMENT` column, the application sometimes needs to know what value it inserted. For example, the application may need to use the value to insert a foreign key column in a dependent table. The LAST_INSERT_ID() function can be used to get the lasted inserted value for an `AUTO_INCREMENT` column without re-reading the row from the table.

Let's insert a row into the table created in the Creating an InnoDB Table with an AUTO_INCREMENT Column section and then use the LAST_INSERT_ID() function:

1. Connect to the server using MariaDB Client:

```
$ mariadb --user=root
```

2. Insert a row with the INSERT statement, but do not specify the `AUTO_INCREMENT` column:

```
INSERT INTO hq_sales.invoices
   (branch_id, customer_id, invoice_date, invoice_total, payment_method)
VALUES
   (1, 4, '2020-05-10 12:37:22', 104.19, 'CREDIT_CARD');
```

3. Execute the LAST_INSERT_ID() function to get the `AUTO_INCREMENT` value for the new row:

```
SELECT LAST_INSERT_ID();

+------------------+
| LAST_INSERT_ID() |
+------------------+
|                4 |
+------------------+
```

4. Select the same row with the SELECT statement to confirm that the `AUTO_INCREMENT` column has the same value:

```
SELECT invoice_id
FROM hq_sales.invoices
WHERE branch_id = 1
AND customer_id = 4
AND invoice_date = '2020-05-10 12:37:22';
```

```
+------------+
| invoice_id |
+------------+
|          4 |
+------------+
```

Choosing an AUTO_INCREMENT Lock Mode for InnoDB

When multiple rows are inserted into a table concurrently, InnoDB needs to be able to generate multiple values concurrently in a safe manner. It has several different modes that can be used to do this, and each mode has its own advantages and disadvantages.

InnoDB's `AUTO_INCREMENT` lock mode is configured with the innodb_autoinc_lock_mode system variable. Users can choose between 3 different values:

Value	Description
0	• This value configures Traditional Lock Mode. • Don't use traditional lock mode. • Traditional lock mode performs very poorly. • In traditional lock mode, InnoDB holds a table-level lock while generating AUTO_INCREMENT values.
1	• This value configures Consecutive Lock Mode. • Consecutive lock mode is the default lock mode. • In consecutive lock mode, InnoDB holds a table-level lock while generating AUTO_INCREMENT values for statements that insert multiple new rows. However, InnoDB uses a lightweight internal lock to improve performance when generating an AUTO_INCREMENT value for statements that insert a single new row.
2	• This value configures Interleaved Lock Mode. • Interleaved lock mode is the recommended lock mode for best performance. • If Galera Cluster is being used, then interleaved lock mode must be configured.

• In interleaved lock mode, InnoDB never holds a table-level lock while generating `AUTO_INCREMENT` values. • Interleaved lock mode is not safe to use if binlog_format is set to `STATEMENT`.|

Configuring the AUTO_INCREMENT Lock Mode for InnoDB

The innodb_autoinc_lock_mode system variable configures the `AUTO_INCREMENT` Lock Mode for InnoDB.

1. Choose a configuration file for custom changes to system variables and options.

It is not recommended to make custom changes to Enterprise Server's default configuration files, because your custom changes can be overwritten by other default configuration files that are loaded after.

Ensure that your custom changes are read last by creating a custom configuration file in one of the included directories. Configuration files in included directories are read in alphabetical order. Use the z- prefix in the file name to ensure that your custom configuration file is read last.

Some example configuration file paths for different distributions are shown in the following table:

Distributions	Example configuration file path
CentOS RHEL Rocky Linux SLES	/etc/my.cnf.d/z-custom-mariadb.cnf
Debian Ubuntu	/etc/mysql/mariadb.conf.d/z-custom-mariadb.cnf

2. Set the innodb_autoinc_lock_mode system variable in the configuration file.
   It needs to be set in a group that will be read by MariaDB Server, such as [mariadb] or [server].

For example:

```
[mariadb]
...
innodb_autoinc_lock_mode = 2
```

3. Restart the server:

```
$ sudo systemctl restart mariadb
```

Setting a Table's Next AUTO_INCREMENT Value

A table's next `AUTO_INCREMENT` value can be set with the ALTER TABLE statement. The value is set using the `AUTO_INCREMENT` table option.

Let's alter the `AUTO_INCREMENT` value for the table created in the Creating an InnoDB Table with an AUTO_INCREMENT Column section and then insert a row into the table, so we can confirm that it uses the new value:

1. Connect to the server using MariaDB Client:

```
$ mariadb --user=root
```

2. Alter the table's next `AUTO_INCREMENT` value with the ALTER TABLE statement:

```
ALTER TABLE hq_sales.invoices
   AUTO_INCREMENT = 100;
```

3. Insert a row with the INSERT statement, but do not specify the `AUTO_INCREMENT` column:

```
INSERT INTO hq_sales.invoices
   (branch_id, customer_id, invoice_date, invoice_total, payment_method)
VALUES
   (1, 5, '2020-05-10 12:43:19', 1105.98, 'CREDIT_CARD');
```

4. Execute the LAST_INSERT_ID() function to get the `AUTO_INCREMENT` value for the new row:

```
SELECT LAST_INSERT_ID();

+------------------+
| LAST_INSERT_ID() |
+------------------+
|              100 |
+------------------+
```

5. Select the same row with the SELECT statement to confirm that the `AUTO_INCREMENT` column has the same value:

```
SELECT invoice_id
FROM hq_sales.invoices
WHERE branch_id = 1
AND customer_id = 5
AND invoice_date = '2020-05-10 12:43:19';

+------------+
| invoice_id |
+------------+
|        100 |
+------------+
```

Configure the Offset and Increment Values

The offset and increment values can be configured by setting the auto_increment_offset and auto_increment_increment system variables.

When Galera Cluster is used, the offset and increment values are managed automatically by default. They can be managed manually by disabling the wsrep_auto_increment_control system variable.

FOREIGN KEY Constraints

In MariaDB Server, `FOREIGN KEY` constraints are key elements in defining relationships between InnoDB tables: they ensure referential integrity by maintaining valid associations between rows in parent and child tables. Changes in the parent table can either be restricted or propagated to maintain consistency with child tables.

Overview

MariaDB Server supports `FOREIGN KEY` constraints to define referential constraints between InnoDB tables:

- Referential constraints allow the database to automatically ensure that each row in the child table is associated with a valid row in the parent table
- If the row in the parent table changes, MariaDB Server can block the change to protect child rows, or propagate the change to the child rows

Term Definitions

Term	Definition
parent table	A table that has a foreign key.
child table	A table that is referenced by a foreign key.

Uses Cases for Foreign Keys

Foreign keys allow the database to handle certain types of referential constraint checks, so that the application does not have to handle them. As a consequence, application logic can be simplified.

Some example use cases are described below.

Managing Accounts Use Case

Many different applications have account management features. Foreign keys can be used to simplify certain aspects of managing accounts, such as:

- If an account is deleted, foreign keys can be used to automatically delete data associated with the account.
- If an account is deleted, foreign keys can be used to automatically disassociate its data, so that it is no longer associated with any account.
- If an account's user name or user ID is updated, foreign keys can be used to automatically associate its data with the new user name or user ID.

Managing Store Inventory Use Case

Foreign keys can also be used to simplify certain aspects of managing a store inventory, such as:

- If a product is deleted, foreign keys can be used to automatically delete data associated with the product, such as reviews and images.
- If a product's name is changed, foreign keys can be used to automatically associate the new name with the product's other data.
- If a customer purchases a product, foreign keys can be used to associate the order with the product.
- If a customer reviews a product, foreign keys can be used to associate the review with the product.

Operating on InnoDB Tables with Foreign Keys

When an InnoDB table has a foreign key or when it is referenced by a foreign key, InnoDB performs a referential constraint check when certain types of operations try to write to the table. The specific details depend on whether the table is a parent table or a child table.

Operating on a Parent Table

When an InnoDB table has a foreign key, it is known as a parent table. InnoDB performs referential constraint checks for the following operations on parent tables:

- UPDATE
- DELETE

When InnoDB performs a referential constraint check, the outcome depends on several factors. The following table describes the details:

Operation	Result of Constraint Check	Action	Consequence
UPDATE	InnoDB finds corresponding rows in the child table	ON UPDATE RESTRICT	• Fails with ER_ROW_IS_REFERENCED_2 error code
UPDATE	InnoDB finds corresponding rows in the child table	ON UPDATE NO ACTION	•. Fails with ER_ROW_IS_REFERENCED_2 error code
UPDATE	InnoDB finds corresponding rows in the child table	ON UPDATE CASCADE	• Success. • Row in the parent table is updated. • Corresponding rows in the child table are also updated with the new foreign key value. If the child table has an update trigger, the trigger will not be executed for the update.
UPDATE	InnoDB finds corresponding rows in the child table	ON UPDATE SET NULL	• Success. • Row in the parent table is updated. • Corresponding rows in the child table are also updated with NULL. If the child table has an update trigger, the trigger will not be executed for the update.
UPDATE	InnoDB does not find any corresponding rows in the child table	NA	• Success. • Row in the parent table is updated
DELETE	InnoDB finds corresponding rows in the child table	ON DELETE RESTRICT	• Fails with ER_ROW_IS_REFERENCED_2 error code
DELETE	InnoDB finds corresponding rows in the child table	ON DELETE NO ACTION	• Fails with EER_ROW_IS_REFERENCED_2 error code
DELETE	InnoDB finds corresponding rows in the child table	ON DELETE CASCADE	• Success. • Row in the parent table is deleted. • Corresponding rows in the child table are also deleted. If the child table has a delete trigger, the trigger will not be executed for the delete.
DELETE	InnoDB finds rows in the child table for the row	ON DELETE SET NULL	• Success. • Row in the parent table is deleted. • Corresponding rows in the child table are updated with NULL. If the child table has an update trigger, the trigger will not be executed for the update.
DELETE	InnoDB does not find any rows in the child table for the row	NA	• Success. • Row in the parent table is deleted

Operating on a Child Table

When an InnoDB table is referenced by a foreign key, it is known as a child table. InnoDB performs referential constraint checks for the following operations on child tables:

- INSERT
- UPDATE
- DROP TABLE

When InnoDB performs a referential constraint check, the outcome depends on several factors. The following table describes the details:

Operation	Result of Constraint Check	Consequence
INSERT	New foreign key value is present in parent table	Success
INSERT	New foreign key value is not present in parent table	Fails with ER_NO_REFERENCED_ROW_2 error code
INSERT	New foreign key value is NULL	Success
UPDATE	New foreign key value is present in parent table	Success
UPDATE	New foreign key value is not present in parent table	Fails with ER_NO_REFERENCED_ROW_2 error code
UPDATE	New foreign key value is NULL	Success
DROP TABLE	Table is referenced by a foreign key	Fails with ER_NO_REFERENCED_ROW_2 error code

Creating InnoDB Tables with a Foreign Key Constraint

Let's create InnoDB tables with a foreign key constraint after confirming that the default storage engine is InnoDB:

1. Connect to the server using MariaDB Client:

```
$ mariadb --user=root
```

2. Confirm that the default storage engine is InnoDB by checking the default_storage_engine system variable using the SHOW SESSION VARIABLES statement:

```
SHOW SESSION VARIABLES
   LIKE 'default_storage_engine';

+------------------------+--------+
| Variable_name          | Value  |
+------------------------+--------+
| default_storage_engine | InnoDB |
+------------------------+--------+
```

3. If the database does not exist, then create the database for the sequence and table using the CREATE DATABASE statement:

```
CREATE DATABASE hq_sales;
```

4. Create the parent table using the CREATE TABLE statement:

```
CREATE TABLE hq_sales.customers (
   customer_id BIGINT AUTO_INCREMENT NOT NULL,
   customer_name VARCHAR(500) NOT NULL,
   customer_email VARCHAR(200),
   PRIMARY KEY(customer_id)
);
```

5. Create the child table using the CREATE TABLE statement:

```
CREATE TABLE hq_sales.invoices (
   invoice_id BIGINT AUTO_INCREMENT NOT NULL,
   branch_id INT NOT NULL,
   customer_id BIGINT,
   invoice_date DATETIME(6),
   invoice_total DECIMAL(13, 2),
   payment_method ENUM('NONE', 'CASH', 'WIRE_TRANSFER', 'CREDIT_CARD', 'GIFT_CARD'),
   PRIMARY KEY(invoice_id),
   CONSTRAINT fk_invoices_customers
      FOREIGN KEY (customer_id) REFERENCES hq_sales.customers (customer_id)
      ON DELETE RESTRICT
      ON UPDATE RESTRICT
);
```

6. Insert some rows into the parent table using the INSERT statement:

```
INSERT INTO hq_sales.customers (customer_id, name)
   VALUES
   (1, 'John Doe'),
   (2, 'Jane Doe');
```

7. Insert a row into the child table for each row in the parent table using the INSERT statement:

```
INSERT INTO hq_sales.invoices
   (branch_id, customer_id, invoice_date, invoice_total, payment_method)
VALUES
   (1, 1, '2020-05-10 12:35:10', 1087.23, 'CREDIT_CARD'),
   (1, 2, '2020-05-10 14:17:32', 1508.57, 'WIRE_TRANSFER');
```

8. Attempt to delete a row from the parent table that has a corresponding row in the child table using the `DELETE` statement:

```
DELETE FROM hq_sales.customers
   WHERE customer_id = 1;
```

This will fail with the ER_ROW_IS_REFERENCED_2 error code as explained in the Operating on a Parent Table section:

```
ERROR 1451 (23000): Cannot delete or update a parent row: a foreign key constraint fails
   (`hq_sales`.`invoices`, CONSTRAINT `fk_invoices_customers`
   FOREIGN KEY (`customer_id`) REFERENCES `customers` (`customer_id`))
```

Attempt to insert a row into the child table for a non-existent row in the parent table using the INSERT statement:

```
INSERT INTO hq_sales.invoices
   (branch_id, customer_id, invoice_date, invoice_total, payment_method)
VALUES
   (1, 3, '2020-05-10 14:25:16', 227.15, 'CASH');
```

This will fail with the ER_NO_REFERENCED_ROW_2 error code as explained in the Operating on a Child Table section:

```
ERROR 1452 (23000): Cannot add or update a child row: a foreign key constraint fails
   (`hq_sales`.`invoices`, CONSTRAINT `fk_invoices_customers`
   FOREIGN KEY (`customer_id`) REFERENCES `customers` (`customer_id`))
```

Adding a Foreign Key Constraint to an InnoDB Table

Let's create InnoDB tables after confirming that the default storage engine is InnoDB, and then let's add a foreign key constraint between them:

1. Connect to the server using MariaDB Client:

```
$ mariadb --user=root
```

2. Confirm that the default storage engine is InnoDB by checking the default_storage_engine system variable using the SHOW SESSION VARIABLES statement:

```
SHOW SESSION VARIABLES
   LIKE 'default_storage_engine';

+------------------------+--------+
| Variable_name          | Value  |
+------------------------+--------+
| default_storage_engine | InnoDB |
+------------------------+--------+
```

3. If the database does not exist, then create the database for the sequence and table using the CREATE DATABASE statement:

```
CREATE DATABASE hq_sales;
```

4. Create the parent table using the CREATE TABLE statement:

```
CREATE TABLE hq_sales.customers (
   customer_id BIGINT AUTO_INCREMENT NOT NULL,
   customer_name VARCHAR(500) NOT NULL,
   customer_email VARCHAR(200),
   PRIMARY KEY(customer_id)
);
```

5. Create the child table using the CREATE TABLE statement:

```
CREATE TABLE hq_sales.invoices (
   invoice_id BIGINT AUTO_INCREMENT NOT NULL,
   branch_id INT NOT NULL,
   customer_id BIGINT,
   invoice_date DATETIME(6),
   invoice_total DECIMAL(13, 2),
   payment_method ENUM('NONE', 'CASH', 'WIRE_TRANSFER', 'CREDIT_CARD', 'GIFT_CARD'),
   PRIMARY KEY(invoice_id)
);
```

6. Alter the child table to add the foreign key constraint using the ALTER TABLE statement:

```
ALTER TABLE hq_sales.invoices ADD CONSTRAINT fk_invoices_customers
      FOREIGN KEY (customer_id) REFERENCES hq_sales.customers (customer_id)
      ON DELETE RESTRICT
      ON UPDATE RESTRICT;
```

7. Insert some rows into the parent table using the INSERT statement:

```
INSERT INTO hq_sales.customers (customer_id, name)
   VALUES
   (1, 'John Doe'),
   (2, 'Jane Doe');
```

8. Insert a row into the child table for each row in the parent table using the INSERT statement:

```
INSERT INTO hq_sales.invoices
   (branch_id, customer_id, invoice_date, invoice_total, payment_method)
VALUES
   (1, 1, '2020-05-10 12:35:10', 1087.23, 'CREDIT_CARD'),
   (1, 2, '2020-05-10 14:17:32', 1508.57, 'WIRE_TRANSFER');
```

9. Attempt to delete a row from the parent table that has a corresponding row in the child table using the DELETE statement:

```
DELETE FROM hq_sales.customers
   WHERE customer_id = 1;
```

This will fail with the ER_ROW_IS_REFERENCED_2 error code as explained in the Operating on a Parent Table section:

```
ERROR 1451 (23000): Cannot delete or update a parent row: a foreign key constraint fails
   (`hq_sales`.`invoices`, CONSTRAINT `fk_invoices_customers`
   FOREIGN KEY (`customer_id`) REFERENCES `customers` (`customer_id`))
```

10. Attempt to insert a row into the child table for a non-existent row in the parent table using the INSERT statement:

```
INSERT INTO hq_sales.invoices
   (branch_id, customer_id, invoice_date, invoice_total, payment_method)
VALUES
   (1, 3, '2020-05-10 14:25:16', 227.15, 'CASH');
```

This will fail with the ER_NO_REFERENCED_ROW_2 error code as explained in the Operating on a Child Table section:

```
ERROR 1452 (23000): Cannot add or update a child row: a foreign key constraint fails
   (`hq_sales`.`invoices`, CONSTRAINT `fk_invoices_customers`
   FOREIGN KEY (`customer_id`) REFERENCES `customers` (`customer_id`))
```

Dropping a Foreign Key Constraint from an InnoDB Table

Let's drop the foreign key constraint from the child table created in the Creating InnoDB Tables with a Foreign Key Constraint section:

1. Connect to the server using MariaDB Client:

```
$ mariadb --user=root
```

2. Obtain the name of the foreign key constraint by querying the information_schema.TABLE_CONSTRAINTS table:

```
SELECT CONSTRAINT_NAME
FROM information_schema.TABLE_CONSTRAINTS
WHERE TABLE_SCHEMA = 'hq_sales'
AND TABLE_NAME = 'invoices'
AND CONSTRAINT_TYPE = 'FOREIGN KEY';
```

```
+-----------------------+
| CONSTRAINT_NAME       |
+-----------------------+
| fk_invoices_customers |
+-----------------------+
```

3. Drop the foreign key constraint from the child table using the ALTER TABLE statement:

```
ALTER TABLE hq_sales.invoices DROP FOREIGN KEY fk_invoices_customers;
```

Temporarily Disabling Foreign Key Constraint Checks

When performing bulk data loads, dropping a table, or rebuilding a table, it can improve performance to temporarily disable foreign key constraint checks. Foreign key constraint checks can be temporarily disabled by setting the session value for the `foreign_key_checks` system variable. If foreign key constraint checks are temporarily disabled, then rows can be inserted that violate the constraint, so users must proceed with caution. This feature is most useful when you are loading a data set that is known to be valid.

Let's temporarily disable foreign key constraint checks, and then perform some tasks with the tables created in the Creating InnoDB Tables with a Foreign Key Constraint section:

1. Connect to the server using MariaDB Client:

```
$ mariadb --user=root
```

2. Temporarily disable foreign key constraint checks by setting the foreign_key_checks system variable with the SET SESSION statement:

```
SET SESSION foreign_key_checks=OFF;
```

3. If you want to test how to introduce inconsistencies, then attempt to delete a row from the parent table that has a corresponding row in the child table using the DELETE statement:

```
DELETE FROM hq_sales.customers
   WHERE customer_id = 1;
```

This operation would usually fail with the ER_NO_REFERENCED_ROW error code as explained in the Operating on a Parent Table section, but if foreign key constraint checks are disable, then it will succeed.

4. If you want to test how to introduce inconsistencies, then also attempt to insert a row into the child table for a non-existent row in the parent table using the INSERT statement:

```
INSERT INTO hq_sales.invoices
   (branch_id, customer_id, invoice_date, invoice_total, payment_method)
VALUES
   (1, 3, '2020-05-10 14:25:16', 227.15, 'CASH');
```

This operation would usually fail with the ER_NO_REFERENCED_ROW_2 error code as explained in the Operating on a Child Table section, but if foreign key constraint checks are disable, then it will succeed.

5. Re-enable foreign key constraint checks by setting the foreign_key_checks system variable with the SET SESSION statement:

```
SET SESSION foreign_key_checks=ON;
```

Special Cases

Foreign Key Constraint Namespace

When a foreign key constraint is created without a name, InnoDB implicitly gives it a name in the format:

```
<table_name>_ibfk_<constraint_count>
```

If foreign key constraints are explicitly created with names in the same format, it is possible for collisions to occur during table renames. In that case, the MariaDB Error Log would contain messages like the following:

```
2021-06-16 11:50:39 139702710404864 [ERROR] InnoDB: Possible reasons:
2021-06-16 11:50:39 139702710404864 [ERROR] InnoDB: (1) Table rename would cause two FOREIGN KEY
constraints to have the same internal name in case-insensitive comparison.
2021-06-16 11:50:39 139702710404864 [ERROR] InnoDB: (2) Table `test`.`t3` exists in the InnoDB internal
data dictionary though MySQL is trying to rename table `test`.`t2b` to it. Have you deleted the .frm file
and not used DROP TABLE?
2021-06-16 11:50:39 139702710404864 [ERROR] InnoDB: If table `test`.`t3` is a temporary table #sql...,
then it can be that there are still queries running on the table, and it will be dropped automatically
when the queries end. You can drop the orphaned table inside InnoDB by creating an InnoDB table with the
same name in another database and copying the .frm file to the current database. Then MySQL thinks the
table exists, and DROP TABLE will succeed.
```

Dependence on an Index

A foreign key constraint requires an index on the column. If a foreign key constraint is added to a column without an index, InnoDB will automatically create an index to enforce the foreign key constraint.

When the foreign_key_checks system variable is disabled, it is possible to drop the index used by a foreign key constraint. When the foreign_key_checks system variable is re-enabled, InnoDB will have no way to enforce the foreign key constraint, so all operations that could potentially violate the foreign key constraint will fail.

This page is: Copyright © 2026 MariaDB. All rights reserved.

NOT NULL Constraints

When creating a table, you can define a column with a `NOT NULL` constraint to prevent null values. This constraint ensures data integrity by guaranteeing that a column must always contain a value. If an attempt is made to insert or update a row with a null value in a `NOT NULL` column, the operation will be rejected, thus maintaining the integrity of the database.

Overview

MariaDB Server supports `NOT NULL` constraints to ensure that a column's value is not set to `NULL`:

When a column is declared with a `NOT NULL` constraint, Enterprise Server rejects operations that would write a NULL value to the column

CREATE TABLE

CREATE TABLE and NOT NULL Constraints

With MariaDB Server, the CREATE TABLE statement can be used to create a new table with a `NOT NULL` constraint on one or more columns:

```
CREATE TABLE hq_sales.invoices (
   invoice_id BIGINT UNSIGNED NOT NULL,
   branch_id INT NOT NULL,
   customer_id INT,
   invoice_date DATETIME(6),
   invoice_total DECIMAL(13, 2),
   payment_method ENUM('NONE', 'CASH', 'WIRE_TRANSFER', 'CREDIT_CARD', 'GIFT_CARD'),
   PRIMARY KEY (invoice_id)
);
```

ALTER TABLE

ALTER TABLE .. MODIFY COLUMN .. NOT NULL

With MariaDB Server, the ALTER TABLE statement can be used to add the `NOT NULL` constraint to a column using the `MODIFY COLUMN` clause:

```
ALTER TABLE hq_sales.invoices
   MODIFY COLUMN customer_id INT NOT NULL;
ALTER TABLE .. MODIFY COLUMN .. NULL
```

With MariaDB Server, the ALTER TABLE statement can be used to remove the `NOT NULL` constraint from a column using the `MODIFY COLUMN` clause:

```
ALTER TABLE hq_sales.invoices
   MODIFY COLUMN customer_id INT NULL;
```

PRIMARY KEY Constraints

Using an `AUTO_INCREMENT` column as the primary key in MariaDB is beneficial for ensuring unique row identification and efficient data retrieval. This approach automatically generates a unique integer for each new row, simplifying primary key management. It is especially useful in tables where data insertion occurs frequently, as it facilitates quick indexing and minimizes storage overhead due to its numeric nature. This practice helps maintain optimal performance in database operations, particularly when combined with clustered indexing in InnoDB.

Overview

MariaDB Server supports `PRIMARY KEY` constraints to uniquely identify rows:

There can only be a single primary key for a given table.

- InnoDB uses the primary key as a clustered index, which means that InnoDB stores table data in the order determined by the primary key.
- Primary key indexes are B+ trees, which are very efficient for searching for exact values, performing range scans, and checking uniqueness.
- If no primary key is defined for a table, then InnoDB will use the table's first `NOT NULL` unique index as the table's primary key.
- If no primary key or `NOT NULL` unique index is defined for a table, then InnoDB will automatically create a primary key called `GEN_CLUST_INDEX`, using an internal `48-bit DB_ROW_ID` column as the key. Replication with such tables can be very slow, especially when binlog_format is `MIXED or ROW`!
- For best performance, users should always create primary keys for their tables, and primary keys should be short, because the primary key columns are duplicated in every secondary index record.

Using an AUTO_INCREMENT Column as the Primary Key

If your table does not have a column or a set of columns that could act as a natural primary key, then you can define a single `AUTO_INCREMENT` column, which can serve as the table's primary key. See InnoDB AUTO_INCREMENT Columns for more details.

Using a Sequence-backed Column as the Primary Key

If your table does not have a column or a set of columns that could act as a natural primary key, then you can use a sequence to generate an integer value to use as the table's primary key. Sequences were first added in MariaDB Server 10.3 and MariaDB Community Server 10.3. See InnoDB Sequences for more details.

Creating an InnoDB Table with a Single Column Primary Key

Let's create an InnoDB table with a single column primary key after confirming that the default storage engine is InnoDB:

1. Connect to the server using MariaDB Client:

```
$ mariadb --user=root
```

2. Confirm that the default storage engine is InnoDB by checking the default_storage_engine system variable using the SHOW SESSION VARIABLES statement:

```
SHOW SESSION VARIABLES
   LIKE 'default_storage_engine';

+------------------------+--------+
| Variable_name          | Value  |
+------------------------+--------+
| default_storage_engine | InnoDB |
+------------------------+--------+
```

3. If the database does not exist, then create the database for the table using the CREATE DATABASE statement:

```
CREATE DATABASE hq_sales;
```

4. Create the table using the CREATE TABLE statement and specify the primary key with the PRIMARY KEY() clause:

```
CREATE TABLE hq_sales.invoices (
   invoice_id BIGINT UNSIGNED NOT NULL,
   branch_id INT NOT NULL,
   customer_id INT,
   invoice_date DATETIME(6),
   invoice_total DECIMAL(13, 2),
   payment_method ENUM('NONE', 'CASH', 'WIRE_TRANSFER', 'CREDIT_CARD', 'GIFT_CARD'),
   PRIMARY KEY(invoice_id)
);
```

For a single column primary key, the primary key can also be specified with the `PRIMARY KEY` column option:

```
CREATE TABLE hq_sales.invoices (
   invoice_id BIGINT UNSIGNED NOT NULL PRIMARY KEY,
   branch_id INT NOT NULL,
   customer_id INT,
   invoice_date DATETIME(6),
   invoice_total DECIMAL(13, 2),
   payment_method ENUM('NONE', 'CASH', 'WIRE_TRANSFER', 'CREDIT_CARD', 'GIFT_CARD')
);
```

Creating an InnoDB Table with a Composite Primary Key

Let's create an InnoDB table with a composite (multi-column) primary key after confirming that the default storage engine is InnoDB:

1. Connect to the server using MariaDB Client:

```
$ mariadb --user=root
```

2. Confirm that the default storage engine is InnoDB by checking the default_storage_engine system variable using the SHOW SESSION VARIABLES statement:

```
SHOW SESSION VARIABLES
   LIKE 'default_storage_engine';

+------------------------+--------+
| Variable_name          | Value  |
+------------------------+--------+
| default_storage_engine | InnoDB |
+------------------------+--------+
```

3. If the database does not exist, then create the database for the table using the CREATE DATABASE statement:

```
CREATE DATABASE hq_sales;
```

4. Create the table using the CREATE TABLE statement and specify the primary key with the PRIMARY KEY() clause:

```
CREATE TABLE hq_sales.invoices (
   invoice_id BIGINT UNSIGNED NOT NULL,
   branch_id INT NOT NULL,
   customer_id INT,
   invoice_date DATETIME(6),
   invoice_total DECIMAL(13, 2),
   payment_method ENUM('NONE', 'CASH', 'WIRE_TRANSFER', 'CREDIT_CARD', 'GIFT_CARD'),
   PRIMARY KEY(invoice_id, branch_id)
);
```

Adding a Primary Key to an InnoDB Table

Let's create an InnoDB table without a primary key, and then add a primary key to it:

1. Connect to the server using MariaDB Client:

```
$ mariadb --user=root
```

2. Confirm that the default storage engine is InnoDB by checking the default_storage_engine system variable using the SHOW SESSION VARIABLES statement:

```
SHOW SESSION VARIABLES
   LIKE 'default_storage_engine';

+------------------------+--------+
| Variable_name          | Value  |
+------------------------+--------+
| default_storage_engine | InnoDB |
+------------------------+--------+
```

3. If the database does not exist, then create the database for the table using the CREATE DATABASE statement:

```
CREATE DATABASE hq_sales;
```

4. Create the table without a primary key using the CREATE TABLE statement:

```
CREATE TABLE hq_sales.invoices (
   invoice_id BIGINT UNSIGNED NOT NULL,
   branch_id INT NOT NULL,
   customer_id INT,
   invoice_date DATETIME(6),
   invoice_total DECIMAL(13, 2),
   payment_method ENUM('NONE', 'CASH', 'WIRE_TRANSFER', 'CREDIT_CARD', 'GIFT_CARD')
);
```

5. Alter the table using the ALTER TABLE statement and specify the new primary key with the ADD PRIMARY KEY() clause:

```
ALTER TABLE hq_sales.invoices ADD PRIMARY KEY (invoice_id);
```

Dropping a Primary Key from an InnoDB Table

Let's drop the primary key from the table created in the create an InnoDB table without a primary key section:

1. Alter the table using the ALTER TABLE statement and specify the `DROP PRIMARY KEY` clause:

```
ALTER TABLE hq_sales.invoices DROP PRIMARY KEY;
```

Changing a Primary Key for an InnoDB Table

Let's change the primary key from the table created in the create an InnoDB table without a primary key section:

1. Alter the table using the ALTER TABLE statement and specify the `DROP PRIMARY KEY` clause to drop the old primary key, and specify the new primary key with the `ADD PRIMARY KEY()` clause:

```
ALTER TABLE hq_sales.invoices
   DROP PRIMARY KEY,
   ADD PRIMARY KEY (invoice_id, branch_id);
```

Finding Tables without Primary Keys

For best performance, every InnoDB table should have a primary key. It is possible to find tables without a primary key using a basic SELECT statement.

Let's create an InnoDB table without a primary key, and then use a SELECT statement to confirm that it does not have one:

1. Connect to the server using MariaDB Client:

```
$ mariadb --user=root
```

2. Confirm that the default storage engine is InnoDB by checking the default_storage_engine system variable using the SHOW SESSION VARIABLES statement:

```
SHOW SESSION VARIABLES
   LIKE 'default_storage_engine';

+------------------------+--------+
| Variable_name          | Value  |
+------------------------+--------+
| default_storage_engine | InnoDB |
+------------------------+--------+
```

3. If the database does not exist, then create the database for the table using the CREATE DATABASE statement:

```
CREATE DATABASE hq_sales;
```

4. Create the table without a primary key using the CREATE TABLE statement:

```
CREATE TABLE hq_sales.invoices (
   invoice_id BIGINT UNSIGNED NOT NULL,
   branch_id INT NOT NULL,
   customer_id INT,
   invoice_date DATETIME(6),
   invoice_total DECIMAL(13, 2),
   payment_method ENUM('NONE', 'CASH', 'WIRE_TRANSFER', 'CREDIT_CARD', 'GIFT_CARD')
);
```

5. Query the information_schema.TABLES and information_schema.KEY_COLUMN_USAGE tables to find InnoDB tables that do not have a primary key:

```
SELECT t.TABLE_SCHEMA, t.TABLE_NAME
FROM information_schema.TABLES AS t
LEFT JOIN information_schema.KEY_COLUMN_USAGE AS c
ON t.TABLE_SCHEMA = c.CONSTRAINT_SCHEMA
   AND t.TABLE_NAME = c.TABLE_NAME
   AND c.CONSTRAINT_NAME = 'PRIMARY'
WHERE t.TABLE_SCHEMA != 'mysql'
   AND t.ENGINE = 'InnoDB'
   AND c.CONSTRAINT_NAME IS NULL;
```

```
+--------------+------------+
| TABLE_SCHEMA | TABLE_NAME |
+--------------+------------+
| hq_sales     | invoices   |
+--------------+------------+
```

6. To add a primary key, alter the table using the ALTER TABLE statement, and specify the primary key with the `ADD PRIMARY KEY()` clause:

```
ALTER TABLE hq_sales.invoices ADD PRIMARY KEY (invoice_id);
```

Handling Duplicate Key Errors

A primary key uniquely identifies every row. Therefore, if a second row is inserted with an identical value, it will fail.

Let's try to insert two identical primary key values into the table created in the Creating an InnoDB Table with a Single Column Primary Key section:

1. Insert a row with the INSERT statement:

```
INSERT INTO hq_sales.invoices
   (invoice_id, branch_id, customer_id, invoice_date, invoice_total, payment_method)
VALUES
   (1, 1, 1, '2020-05-10 12:35:10', 1087.23, 'CREDIT_CARD');
```

2. Insert a second row that has the same primary key value with the INSERT statement:

```
INSERT INTO hq_sales.invoices
   (invoice_id, branch_id, customer_id, invoice_date, invoice_total, payment_method)
VALUES
   (1, 1, 2, '2020-05-10 14:17:32', 1508.57, 'WIRE_TRANSFER');
```

This will fail with the ER_DUP_ENTRY error code:

```
ERROR 1062 (23000): Duplicate entry '1' for key 'PRIMARY'
```

3. Fix the problem by inserting the row with a unique primary key value:

```
INSERT INTO hq_sales.invoices
   (invoice_id, branch_id, customer_id, invoice_date, invoice_total, payment_method)
VALUES
   (2, 1, 2, '2020-05-10 14:17:32', 1508.57, 'WIRE_TRANSFER');
```

To easily generate unique values for a primary key, consider using one of the following options:

- InnoDB AUTO_INCREMENT Columns
- InnoDB Sequences

This page is: Copyright © 2026 MariaDB. All rights reserved.

UNIQUE Constraints

The `unique_checks` system variable in MariaDB Server can be utilized to disable unique checks, which might be useful in specific scenarios where enforcing unique constraints temporarily is not required. This can enhance performance during bulk inserts, for instance.

Overview

MariaDB Server supports `UNIQUE` constraints to ensure that a column's value is unique within a table:

- MariaDB Server uses unique indexes to speed up query execution and enforce unique constraints
- MariaDB Server supports single column and composite (multi-column) unique indexes
- MariaDB Community Server can have up to 64 total indexes for a given table.
- MariaDB Server can have up to 128 total indexes for a given table.
- InnoDB stores unique indexes in the same tablespace file as the clustered index and data.
- Unique indexes are B+ trees, which are very efficient for searching for exact values, performing range scans, and checking uniqueness.
- If no primary key is defined for a table, then InnoDB will use the table's first `NOT NULL` unique index as the table's primary key.
- If no primary key or `NOT NULL` unique index is defined for a table, then InnoDB will automatically create a primary key called `GEN_CLUST_INDEX`, using an internal `48-bit DB_ROW_ID` column as the key. Replication with such tables can be very slow, especially when binlog_format is `MIXED or ROW`.

unique_checks System Variable

MariaDB Server provides the unique_checks system variable, which can be used to disable unique checks.

When unique checks are disabled, the InnoDB change buffer is used for inserts into unique indexes, and duplicate values will not be detected.

Disabling unique checks can speed up bulk data loads, but it is dangerous to do so.

Creating an InnoDB Table with a Single Column Unique Index

Let's create an InnoDB table with a single column unique index after confirming that the default storage engine is InnoDB:

1. Connect to the server using MariaDB Client:

```
$ mariadb --user=root
```

2. Confirm that the default storage engine is InnoDB by checking the default_storage_engine system variable using the SHOW SESSION VARIABLES statement:

```
SHOW SESSION VARIABLES
   LIKE 'default_storage_engine';
```

```
+------------------------+--------+
| Variable_name          | Value  |
+------------------------+--------+
| default_storage_engine | InnoDB |
+------------------------+--------+
```

3. If the database does not exist, then create the database for the table using the CREATE DATABASE statement:

```
CREATE DATABASE hq_sales;
```

4. Create the table using the CREATE TABLE statement and specify the unique index with the `UNIQUE INDEX()` clause:

```
CREATE TABLE hq_sales.customers (
   customer_id BIGINT AUTO_INCREMENT NOT NULL,
   customer_name VARCHAR(500),
   customer_email VARCHAR(200),
   PRIMARY KEY(customer_id),
   UNIQUE INDEX(customer_email)
);
```

5. For a single column unique index, the unique index can also be specified with the `UNIQUE` column option:

```
CREATE TABLE hq_sales.customers (
   customer_id BIGINT AUTO_INCREMENT NOT NULL,
   customer_name VARCHAR(500),
   customer_email VARCHAR(200) UNIQUE,
   PRIMARY KEY(customer_id)
);
```

Creating an InnoDB Table with a Composite Unique Index

Let's create an InnoDB table with a composite (multi-column) unique index after confirming that the default storage engine is InnoDB:

1. Connect to the server using MariaDB Client:

```
$ mariadb --user=root
```

2. Confirm that the default storage engine is InnoDB by checking the default_storage_engine system variable using the SHOW SESSION VARIABLES statement:

```
SHOW SESSION VARIABLES
   LIKE 'default_storage_engine';
```

```
+------------------------+--------+
| Variable_name          | Value  |
+------------------------+--------+
| default_storage_engine | InnoDB |
+------------------------+--------+
```

3. If the database does not exist, then create the database for the table using the CREATE DATABASE statement:

```
CREATE DATABASE hq_sales;
```

4. Create the table using the CREATE TABLE statement and specify the unique index with the UNIQUE INDEX() clause:

```
CREATE TABLE hq_sales.invoices (
   invoice_id BIGINT UNSIGNED NOT NULL,
   branch_id INT NOT NULL,
   customer_id INT,
   invoice_date DATETIME(6),
   invoice_total DECIMAL(13, 2),
   payment_method ENUM('NONE', 'CASH', 'WIRE_TRANSFER', 'CREDIT_CARD', 'GIFT_CARD'),
   PRIMARY KEY(invoice_id),
   UNIQUE INDEX(invoice_date, customer_id, branch_id)
);
```

Creating an InnoDB Table with a Unique Index on a Column Prefix

Let's create an InnoDB table with a unique index on a single column prefix after confirming that the default storage engine is InnoDB:

1. Connect to the server using MariaDB Client:

```
$ mariadb --user=root
```

2. Confirm that the default storage engine is InnoDB by checking the default_storage_engine system variable using the SHOW SESSION VARIABLES statement:

```
SHOW SESSION VARIABLES
   LIKE 'default_storage_engine';
```

```
+------------------------+--------+
| Variable_name          | Value  |
+------------------------+--------+
| default_storage_engine | InnoDB |
+------------------------+--------+
```

3. If the database does not exist, then create the database for the table using the CREATE DATABASE statement:

```
CREATE DATABASE hq_sales;
```

4. Create the table using the CREATE TABLE statement and specify the unique index with the `UNIQUE INDEX()` clause:

```
CREATE TABLE hq_sales.products (
   product_id BIGINT AUTO_INCREMENT NOT NULL,
   product_name VARCHAR(500),
   product_brand VARCHAR(500),
   product_description TEXT,
   PRIMARY KEY(product_id),
   UNIQUE INDEX(product_description(1000))
);
```

The unique index is specified with the `product_description(1000)` prefix, so only the first 1000 characters of the `product_description` column for each row will be indexed and checked for uniqueness.

Adding a Unique Index to an InnoDB Table

Let's create an InnoDB table without a unique index, and then add a unique index to it:

1. Connect to the server using MariaDB Client:

```
$ mariadb --user=root
```

2. Confirm that the default storage engine is InnoDB by checking the default_storage_engine system variable using the SHOW SESSION VARIABLES statement:

```
SHOW SESSION VARIABLES
   LIKE 'default_storage_engine';
```

```
+------------------------+--------+
| Variable_name          | Value  |
+------------------------+--------+
| default_storage_engine | InnoDB |
+------------------------+--------+
```

3. If the database does not exist, then create the database for the table using the CREATE DATABASE statement:

```
CREATE DATABASE hq_sales;
```

4. Create the table without a primary key using the CREATE TABLE statement:

```
CREATE TABLE hq_sales.customers (
   customer_id BIGINT AUTO_INCREMENT NOT NULL,
   customer_name VARCHAR(500),
   customer_email VARCHAR(200),
   PRIMARY KEY(customer_id)
);
```

5. Alter the table using the ALTER TABLE statement and specify the new unique index with the `ADD UNIQUE INDEX()` clause:

```
ALTER TABLE hq_sales.customers ADD UNIQUE INDEX (customer_email);
```

Dropping a Unique Index from an InnoDB Table

Let's drop the unique index from the table created in the Creating an InnoDB Table with a Single Column Unique Index section:

1. Obtain the name of the index by joining the information_schema.INNODB_SYS_INDEXES, information_schema.INNODB_SYS_TABLES, and information_schema.INNODB_SYS_FIELDS tables:

```
SELECT isi.NAME AS index_name, isf.NAME AS index_column
FROM information_schema.INNODB_SYS_INDEXES isi
JOIN information_schema.INNODB_SYS_TABLES ist
ON isi.TABLE_ID = ist.TABLE_ID
JOIN information_schema.INNODB_SYS_FIELDS isf
ON isi.INDEX_ID = isf.INDEX_ID
WHERE ist.NAME = 'hq_sales/customers'
ORDER BY isf.INDEX_ID, isf.POS;
```

```
+----------------+----------------+
| index_name     | index_column   |
+----------------+----------------+
| PRIMARY        | customer_id    |
| customer_email | customer_email |
+----------------+----------------+
```

2. Alter the table using the ALTER TABLE statement and specify the `DROP INDEX` clause:

```
ALTER TABLE hq_sales.customers DROP INDEX customer_email;
```

Rebuilding a Unique Index in an InnoDB Table

Let's rebuild the unique index in the table created in the Creating an InnoDB Table with a Single Column Unique Index section:

1. Obtain the name of the index by joining the information_schema.INNODB_SYS_INDEXES, information_schema.INNODB_SYS_TABLES, and information_schema.INNODB_SYS_FIELDS tables:

```
SELECT isi.NAME AS index_name, isf.NAME AS index_column
FROM information_schema.INNODB_SYS_INDEXES isi
JOIN information_schema.INNODB_SYS_TABLES ist
ON isi.TABLE_ID = ist.TABLE_ID
JOIN information_schema.INNODB_SYS_FIELDS isf
ON isi.INDEX_ID = isf.INDEX_ID
WHERE ist.NAME = 'hq_sales/customers'
ORDER BY isf.INDEX_ID, isf.POS;
```

```
+----------------+----------------+
| index_name     | index_column   |
+----------------+----------------+
| PRIMARY        | customer_id    |
| customer_email | customer_email |
+----------------+----------------+
```

2. Alter the table using the ALTER TABLE statement and specify the `DROP INDEX` clause:

```
ALTER TABLE hq_sales.customers DROP INDEX customer_email;
```

3. Alter the table using the ALTER TABLE statement and specify the unique index with the `ADD UNIQUE INDEX()` clause:

```
ALTER TABLE hq_sales.customers ADD UNIQUE INDEX (customer_email);
```

dbdeployer

> **Note:**
>
> dbdeployer is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

dbdeployer is a tool for installing multiple versions of MariaDB or MySQL in isolation from each other. It is primarily used for easily testing different server versions. It is written in Go, and is a replacement for MySQL Sandbox.

Visit www.dbdeployer.com for details on how to install and use it.

This page is licensed: CC BY-SA / Gnu FDL

innochecksum

innochecksum is a tool for printing checksums for InnoDB files.

Usage

```
innochecksum [options] file_name
```

Description

The tool reads an InnoDB tablespace file, calculates the checksum for each page, compares the calculated checksum to the stored checksum, and reports mismatches, which indicate damaged pages. It was originally developed to speed up verifying the integrity of tablespace files after power outages, but can also be used after file copies. Because checksum mismatches causes InnoDB to deliberately shut down a running server, it can be preferable to use innochecksum rather than waiting for a server in production usage to encounter damaged pages.

> **Note:**
>
> Multiple filenames can be specified by a wildcard (on non-Windows systems only).

innochecksum works with compressed pages, and includes options to analyze leaf pages to estimate how fragmented an index is and how much benefit can be gained from defragmentation.

> **Note:**
>
> innochecksum cannot be used on tablespace files that the server already has open. For such files, you should use CHECK TABLE to check tables within the tablespace. If checksum mismatches are found, you would normally restore the tablespace from backup or start the server and attempt to use mariadb-dump to make a backup of the tables within the tablespace.

Options

innochecksum supports the following options. For options that refer to page numbers, the numbers are zero-based.

Option	Description
-a, –allow-mismatches=#	Maximum checksum mismatch allowed before innochecksum terminates. Defaults to `0`, which terminates on the first mismatch.
-c, –count	Print a count of the number of pages in the file.
-e num, –end-page=#	End at this page number (0-based).
-?, –help	Display help and exits.
-I, –info	Synonym for –help.
-f, –leaf	Examine leaf index pages.
-l fn, –log=fn	Log output to the specified filename *`fn`*.
-m num, –merge=#	Leaf page count, in case of a merge, given number of consecutive pages.
-n, –no-check	Ignore the checksum verification. Before MariaDB 10.6, must be used with the `--write` option.
-p num, –page=#	Check only this page number (0-based).
-D, –page-type-dump=name	Dump the page type info for each page in a tablespace.
-S, –page-type-summary	Display a count of each page type in a tablespace.
-i, –per-page-details	Print out detailed information per page.
-u, –skip-corrupt	Skip corrupt pages.
-r, –skip-freed-pages	
-s num, –start-page=#	Start at this page number (0-based).
-C, –strict-check=name	
-v, –verbose	Verbose mode; print a progress indicator every five seconds.
-V, –version	Display version information and exit.
-w, –write=name	

Examples

Rewriting a CRC32 checksum to replace an invalid checksum:

```
innochecksum --no-check --write crc32 tablename.ibd
```

A count of each page type:

```
innochecksum --page-type-summary data/mysql/gtid_slave_pos.ibd

File::data/mysql/gtid_slave_pos.ibd
================PAGE TYPE SUMMARY==============
#PAGE_COUNT PAGE_TYPE
===============================================
       1    Index page
       0    Undo log page
       1    Inode page

mariadb-access

`mariadb-access` is a tool for checking access privileges, developed by Yves Carlier.

> **CURRENT**
>
> The client tool can alternatively be called by its former name, `mysqlaccess`, via a symlink in Linux, or an alternate binary in Windows.
>
> **< 10.5**
>
> The client tool is called `mysqlaccess`.

It checks the access privileges for a host name, user name, and database combination.

> **Note:**
>
> mariadb-access checks access using only the user, db, and host tables. It does not check table, column, or routine privileges specified in the tables_priv, columns_priv, or procs_priv tables.

Usage

```
mariadb-access [host [user [db]]] OPTIONS
```

If your MariaDB distribution is installed in some non-standard location, you must change the location where *mariadb-access* expects to find the mariadb client. Edit the *mariadb-access* script at approximately line 18. Search for a line that looks like this:

```
$MYSQL = ´/usr/local/bin/mariadb;
path to mariadb executable
```

Change the path to reflect the location where the *mariadb* client tool is stored on your system. Otherwise, a *Broken pipe error* occurs when running *mariadb-access*.

Options

Option	Description
-?, –help	Display help and exit.
-v, –version	Display version.
-u username, –user=username	Username for logging in to the server.
-p[password], –password[=password]	Password to use for user. If omitted, mariadb-access prompts for one.
-h hostname, –host=hostname	Name or IP of the host.
-d dbname, –db=dbname	Name of the database.
-U username, –superuser=username	Connect as superuser.
-P password, –spassword=password	Password for superuser.
-H server, –rhost=server	Remote server to connect to.
–old_server	Connect to a very old MySQL servers (before version 3.21) that does not know how to handle full WHERE clauses.
-b, –brief	Single-line tabular report.
-t, –table	Report in table-format.
–relnotes	Print release-notes.
–plan	Print suggestions/ideas for future releases.
–howto	Some examples of how to run `mariadb-access'.
–debug=N	Enter debug level N (0..3).
–copy	Reload temporary grant tables from original ones.
–preview	Show differences in privileges after making changes in (temporary) grant tables.
–commit	Copy grant rules from temporary tables to grant tables (the grant tables must be flushed afterwards, for example with mariadb-admin reload).
–rollback	Undo the last changes to the grant tables.

Note

At least the user (`-u`) and the database (`-d`) options must be given, even when using wildcards. If no host is provided, `` `localhost' `` is assumed. Wildcards (`?` , `%` , and `_`) are allowed for host, user, and database, but be sure

to escape them from your shell.

mariadb-admin

Overview

`mariadb-admin` is an administration program for the mariadbd daemon. It can be used to:

- Monitor what the MariaDB clients are doing (processlist);
- Get usage statistics and variables from the MariaDB server;
- Create and drop databases;
- Flush (reset) logs, statistics, and tables;
- Kill running queries;
- Stop the server (shutdown);
- Start and stop replicas;
- Check if the server is alive (ping).

> **CURRENT**
>
> The client tool name is `mariadb-admin`. However, it can still be accessed under the old name, `mysqladmin`, via a symlink on Linux or an alternate binary on Windows.
>
> **< 10.5**
>
> The name of the client tool is `mysqladmin`.

Usage

The command to use `mariadb-admin` and the general syntax is:

```
mariadb-admin [options] command [command-arg] [command [command-arg]] ...
```

Options

`mariadb-admin` supports the following options:

Option	Description
–character-sets-dir=*dir*	Directory where the character set files are located.
-C, –compress	Compress all information sent between the client and the server if both support compression.
–connect_timeout=*val*	Maximum time in seconds before connection timeout. The default value is `43200` (12 hours).
-c *val*, –count=*val*	Number of iterations to make. This works with `-i` (`--sleep`) only.

Option	Description
-# [*debug_options*], –debug[=*debug_options*]	Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o,/tmp/mysqladmin.trace`.
–debug-check	Check memory and open file usage on exit.
–debug-info	Print debugging information, memory, and CPU usage statistics when the program exits.
–default-auth=*plugin*	Default authentication client-side plugin to use.
–default-character-set=*name*	Set the default character set.
-f, –force	Don't ask for confirmation on drop database. With multiple statements, continue even if an error occurs.
-?, –help	Display help and exit.
-h *name*, –host=*name*	Hostname to connect to.
-l, –local	Suppress SQL statements from being written to the binary log, by enabling sql_log_bin=0 for flush commands, using `FLUSH LOCAL` rather than `SET sql_log_bin=0`. The privilege required is `RELOAD`.
-b, –no-beep	Turn off beep on error.
-p[*password*], –password[=*password*]	Password to use when connecting to server. If password is not given, it's asked from the terminal.
–pipe, -W	On Windows, connect to the server via a named pipe. This option applies only if the server supports named-pipe connections.
-P *portnum*, –port=*portnum*	
–protocol={tcp|socket|pipe|memory}	The protocol to use for the connection (`tcp`, `socket`, `pipe`, `memory`).
-r, –relative	Show difference between current and previous values when used with `-i`. Only works in combination with `extended-status`.
-O *val*, –set-variable=*val*	Change the value of a variable to *val*. This option is deprecated; you can set variables directly with `--variable-name=val`.

Option	Description
–shutdown_timeout=*val*	Maximum number of seconds to wait for server shutdown. The default value is 3600 (1 hour).
-s, –silent	Silently exit if you can't connect to server.
-i *delay*, –sleep=*delay*	Execute commands repeatedly, sleeping for *delay* seconds in between. The `--count` option determines the number of iterations. If `--count` is not given, `mariadb-admin` executes commands indefinitely until interrupted.
-S *name*, –socket=*name*	For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use.
–ssl	Enables TLS. TLS is also enabled even without setting this option when certain other TLS options are set. The `--ssl` option doesn't enable verifying the server certificate by default. In order to verify the server certificate, you must specify the `--ssl-verify-server-cert` option.
–ssl-ca=*name*	Define a path to a PEM file that should contain one or more X509 certificates for trusted Certificate Authorities (CAs) to use for TLS. This option requires the use of an absolute path, not a relative path. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option implies the `--ssl` option.
–ssl-capath=*name*	Defines a path to a directory that contains one or more PEM files that should each contain one X509 certificate for a trusted Certificate Authority (CA) to use for TLS. This option requires the use of an absolute path, not a relative path. The directory specified by this option needs to be run through the openssl rehash command. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option is only supported if the client was built with OpenSSL or yaSSL. If the client was built with GnuTLS or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms. This option implies the `--ssl` option.
–ssl-cert=*name*	Define a path to the X509 certificate file to use for TLS. This option requires the use of an absolute path, not a relative path. This option implies the `--ssl` option.
–ssl-cipher=*name*	List of permitted ciphers or cipher suites to use for TLS. This option implies the `--ssl` option.
–ssl-crl=*name*	Define a path to a PEM file that should contain one or more revoked X509 certificates to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL or Schannel. If the client was built with yaSSL or GnuTLS, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.
–ssl-crlpath=*name*	Define a path to a directory that contains one or more PEM files that should each contain one revoked X509 certificate to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the openssl rehash command. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL. If the client was built with yaSSL, GnuTLS, or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.
–ssl-key=*name*	Define a path to a private key file to use for TLS. This option requires the use of an absolute path, not a relative path. This option implies the `--ssl` option.
–ssl-verify-server-cert	Enable server certificate verification. This option is disabled by default.
–tls-version=*name*	Accept a comma-separated list of TLS protocol versions. A TLS protocol version will only be enabled if it is present in this list. All other TLS protocol versions will not be permitted. See Secure Connections Overview: TLS Protocol Versions for more information.

Option	Description
-u, –user=*name*	User for login, if not current user.
-v, –verbose	Write more information.
-V, –version	Output version information and exit.
-E, –vertical	Print output vertically. Is similar to '–relative', but prints output vertically.
-w[*count*], –wait[=*count*]	If the connection cannot be established, wait and retry instead of aborting. If a count value is given, it indicates the number of times to retry. The default is one time.
–wait-for-all-slaves	Wait for the last binlog event to be sent to all connected replicas before shutting down. This option is off by default.

Option Files

In addition to reading options from the command line, `mariadb-admin` also reads options from option files. If an unknown option is provided to `mariadb-admin` in an option file, the option is ignored.

The following options relate to how MariaDB command line tools handles option files. They must be given as the first argument on the command line:

Option	Description
–print-defaults	Print the program argument list and exit.
–no-defaults	Don't read default options from any option file.
–defaults-file=#	Only read default options from the given file #.
–defaults-extra-file=#	Read this file after the global files are read.
–defaults-group-suffix=#	In addition to the default option groups, also read option groups with this suffix.

`mariadb-admin` is linked with MariaDB Connector/C. However, MariaDB Connector/C does not yet handle the parsing of option files for this client. That is still performed by the server option file parsing code. See MDEV-19035 for more information.

Option Groups

`mariadb-admin` reads options from the following option groups.

Group	Description
[mysqladmin]	Options read by `mysqladmin`, which includes both MariaDB Server and MySQL Server.
[mariadb-admin]	Options read by mariadb-admin.
[client]	Options read by all MariaDB and MySQL client programs, which includes both MariaDB and MySQL clients. For example, mysqldump.
[client-server]	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients.
[client-mariadb]	Options read by all MariaDB client programs.

Variables

Variables can be set with `--variable-name=value`.

Variables and boolean options	Default value
count	`0`
debug-check	`FALSE`
debug-info	`FALSE`
force	`FALSE`
compress	`FALSE`
character-sets-dir	(No default value)
default-character-set	(No default value)
host	(No default value)
no-beep	`FALSE`
port	`3306`
relative	`FALSE`
socket	`/var/run/mariadbd/mariadbd.sock`
sleep	`0`
ssl	`FALSE`
ssl-ca	(No default value)
ssl-capath	(No default value)
ssl-cert	(No default value)
ssl-cipher	(No default value)
ssl-key	(No default value)
ssl-verify-server-cert	`FALSE`
user	(No default value)
verbose	`FALSE`
vertical	`FALSE`
connect_timeout	43200
shutdown_timeout	3600

Commands

```
mariadb-admin [options] command [command-arg] [command [command-arg]] ...
```

Command is one or more of the following. Commands can be shortened to a unique prefix.

Command	Description
create *db*	Create a database named *db*.
debug	Instruct server to write debug information to log.
drop *db*	Delete a database named *db* and all its tables.

Command	Description
extended-status	Return all status variables and their values.
flush-all-statistics	Flush all statistics tables
flush-all-status	Flush status and statistics.
flush-binary-log	Flush binary log.
flush-client-statistics	Flush client statistics.
flush-engine-log	Flush engine log.
flush-error-log	Flush error log.
flush-general-log	Flush general query log.
flush-hosts	Flush all cached hosts.
flush-index-statistics	Flush index statistics.
flush-logs	Flush all logs.
flush-privileges	Reload grant tables (same as reload).
flush-relay-log	Flush relay log.
flush-slow-log	Flush slow query log.
flush-ssl	Flush SSL certificates. Available from MariaDB 10.6.0.
flush-status	Clear status variables.
flush-table-statistics	Clear table statistics.

Command	Description
flush-tables	Flush all tables.
flush-threads	Flush the thread cache.
flush-user-resources	Flush user resources.
flush-user-statistics	Flush user statistics.
kill id,id,…	Kill mysql threads.
password new-password	Change old password to new-password. The new password can be passed on the command line as the next argument (for example, mariadb-admin password “new_password”, or can be omitted (as long as no other command follows), in which case the user is prompted for a password. If the password contains special characters, it needs to be enclosed in quotation marks. In Windows, the quotes can only be double quotes, as single quotes are assumed to be part of the password. If the server was started with the –skip-grant-tables option, changing the password in this way will have no effect.
old-password new-password	Change old password to new-password using the old pre-MySQL 4.1 format.
ping	Check if `mariadbd` is alive. Return status is `0` if the server is running (even in the case of an error such as access denied), `1` if it is not.
processlist	Show list of active threads in server, equivalent to SHOW PROCESSLIST. With `--verbose`, it is an equivalent to SHOW FULL PROCESSLIST.
reload	Reload grant tables.
refresh	Flush all tables and close and open log files.
shutdown	Take the server down by executing the SHUTDOWN command on the server. If connected to a local server using a Unix socket file, `mariadb-admin` waits until the server’s process ID file is removed, to ensure that the server stopped properly. See also the `--wait-for-all-slaves` option.
status	Give a short status message from the server.
start-all-slaves	Start all replicas.
start-slave	Start replication on a replica server.
stop-all-slaves	Stop all replicas.
stop-slave	Stop replication on a replica server.
variables	Print variables available.
version	Return version as well as status info from the server.

The shutdown Command and the –wait-for-all-slaves Option

The `--wait-for-all-slaves` option can be used in the following scenario.

When a primary server is shut down and goes through the normal shutdown process, it kills client threads in random order. By default, the primary also considers its binary log dump threads to be regular client threads. As a consequence, the binary log dump threads can be killed while client threads still exist. This means that data can be written on the primary during a normal shutdown that won't be replicated. This is true even if semi-synchronous replication is being used.

This problem can be solved by shutting down the server with the `mariadb-admin` utility and by providing the `--wait-for-all-slaves` option:

```
mariadb-admin --wait-for-all-slaves shutdown
```

When the `--wait-for-all-slaves` option is provided, the server only kills its binary log dump threads after all client threads have been killed, and it only completes the shutdown after the last binary log has been sent to all connected replicas.

See Replication Threads: Binary Log Dump Threads and the Shutdown Process for more information.

Examples

Quick check of what the server is doing:

```
shell> mariadb-admin status
Uptime: 8023 Threads: 1 Questions: 14 Slow queries: 0 Opens: 15 Flush tables: 1 Open tables: 8 Queries
per second avg: 0.1
shell> mariadb-admin processlist
+----+-------+-----------+----+---------+------+-------+------------------+
| Id | User | Host | db | Command | Time | State | Info |
+----+-------+-----------+----+---------+------+-------+------------------+
....
+----+-------+-----------+----+---------+------+-------+------------------+
```

More extensive information of what is currently happening, great for troubleshooting a slow server:

```
shell> mariadb-admin --relative --sleep=1 extended-status | grep -v " 0 "
```

Check the variables for a running server:

```
shell> mariadb-admin variables | grep datadir
| datadir | /my/data/ |
```

Use a shortened prefix for the `version` command:

```
shell> mariadb-admin ver
mariadb-admin from 11.1.0-preview-MariaDB, client 9.1 for linux-systemd (x86_64)
Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Server version      11.1.0-preview-MariaDB
Protocol version    10
Connection      localhost via TCP/IP
TCP port        11100
Uptime:         3 min 21 sec

Threads: 1  Questions: 1  Slow queries: 0  Opens: 17  Open tables: 10  Queries per second avg: 0.004
```

Other Ways To Stop mariadbd (Unix)

If connecting as a user that does not have the `SUPER` or `SHUTDOWN` privilege, an error occurs:

```
mariadb-admin: shutdown failed; error: 'Access denied; you need (at least one of) the SHUTDOWN
privilege(s) for this operation'
```

If you don't know the user password, you can still take the `mariadbd` process down like this:

UNIX-LIKE SYSTEMS

```
kill -SIGTERM pid-of-mariadbd-process
```

This command is identical to `mariadb-admin shutdown`.

WINDOWS

```
NET STOP MySQL
```

You can use the SHUTDOWN command from any client.

See Also

- SHUTDOWN
- mytop, a tool similar to `top` on Unix-like systems, that allows to see what the server is doing.

mariadb-conv

> **Note:**
>
> This tool is available from MariaDB 10.5.

`mariadb-conv` is a character set conversion utility for MariaDB.

Usage

```
mariadb-conv [OPTION...] [FILE...]
```

Options

`mariadb-conv` supports the following options:

Option	Description
-f, –from=name	Specifies the encoding of the input.
-t, –to=name	Specifies the encoding of the output.
-c, –continue	Silently ignore conversion errors.
–delimiter=name	Treat the specified characters as delimiters.

By default, `mariadb-conv` exits whenever it encounters any conversion problems, like

- the input byte sequence is not valid in the source character set;
- the character cannot be converted to the target character set.

The `-c` option makes `mariadb-conv` ignore such errors and use the question mark (`?`) to replace bytes in bad input sequences, or unconvertible characters.

The `--delimiter=...` option makes `mariadb-conv` treat the specified characters as delimiters rather than data to convert, so the input is treated as a combination of

- data chunks, which are converted according to the `-f` and `-t` options;
- delimiters, which are not converted and are copied from the input to the output as is.

Examples

Convert the file `file.latin1.txt` from `latin1` to `utf8` :

```
mariadb-conv -f latin1 -t utf8 file.latin1.txt
```

Convert the file `file.latin1.txt` from `latin1` to `utf8`, reading the input data from `stdin`:

```
mariadb-conv -f latin1 -t utf8 < file.latin1.txt
```

Using `mariadb-conv` in a pipe:

```
echo test | ./mariadb-conv -f utf8 -t ucs2 >file.ucs2.txt
```

As a side effect, `mariadb-conv` can be used to list MariaDB data directories in a human readable form. Suppose you create the following tables:

```
SET NAMES utf8;
CREATE OR REPLACE TABLE t1 (a INT);
CREATE OR REPLACE TABLE ß (a INT);
CREATE OR REPLACE TABLE абв (a INT);
CREATE OR REPLACE TABLE ▫▫ (a INT);
```

This statement creates the following files in the MariaDB data directory:

```
@1j.frm
@1j.ibd
@684c@5b50.frm
@684c@5b50.ibd
@g0@h0@i0.frm
@g0@h0@i0.ibd
t1.frm
t1.ibd
```

It's not precisely clear which file stores which table, because MariaDB uses a special table-name-to-file-name encoding.

This command on Linux (assuming an utf-8 console) can print the table list in a readable way:

```
ls | mariadb-conv -f filename -t utf8 --delimiter=".\n"

ß.frm
ß.ibd
▫▫.frm
▫▫.ibd
абв.frm
абв.ibd
t1.frm
t1.ibd
```

> **Note:**
>
> The `--delimiter="\n"` option is needed to make `mariadb-conv` treat the dot character (delimiting the encoded table name from the file extension) and the newline character (delimiting separate lines) as delimiters, rather than as the data to convert (otherwise the conversion would fail).

Windows users can use the following command to list the data directory in the ANSI text console:

```
dir /b | mariadb-conv -c -f filename -t cp850 --delimiter=".\r\n"
```

Note:

- The `-t` options assume a Western machine.
- The `-c` option is needed to ignore conversion errors for Cyrillic and CJK characters.
- `--delimiter=` additionally needs the carriage return character.

mariadb-setpermission

Syntax

```
mariadb-setpermission [options]
```

Description

`mariadb-setpermission` is a Perl script that was originally written and contributed by Luuk de Boer. It requires the DBI and DBD::mysql Perl modules to be installed. `mariadb-setpermission` can help you add users or databases or change passwords in MariaDB.

It interactively sets permissions in the MariaDB grant tables, but does not check permissions which have already been set in MariaDB. So if you can't connect to MariaDB using the permission you just added, take a look at the permissions which have already been set in MariaDB.

The account used when you connect determines which permissions you have when attempting to modify existing permissions in the grant tables.

`mariadb-setpermission` also reads options from the `[client]` and `[perl]` groups in the `.my.cnf` file in your home directory, if the file exists.

The following options are available:

Options

–help	Display a help message and exit.
–host=host_name	Connect to the MariaDB server on the given host.
–password=password	The password to use when connecting to the server. Note that the password value is not optional for this option, unlike for other MariaDB programs Specifying a password on the command line should be considered insecure. You can use an option file to avoid giving the password on the command line.
–port=port_num	The TCP/IP port number to use for the connection.
–socket=path	For connections to localhost, the Unix socket file to use.

–user=user_name	The MariaDB user name to use when connecting to the server.

Example

```
./mariadb-setpermission --user=msandbox --password=msandbox --host=127.0.0.1 --port=11200
########################################################################
## Welcome to the permission setter 1.4 for MariaDB.
## made by Luuk de Boer
########################################################################
What would you like to do:
  1. Set password for an existing user.
  2. Create a database + user privilege for that database
     and host combination (user can only do SELECT)
  3. Create/append user privilege for an existing database
     and host combination (user can only do SELECT)
  4. Create/append broader user privileges for an existing
     database and host combination
     (user can do SELECT,INSERT,UPDATE,DELETE)
  5. Create/append quite extended user privileges for an
     existing database and host combination (user can do
     SELECT,INSERT,UPDATE,DELETE,CREATE,DROP,INDEX,
     LOCK TABLES,CREATE TEMPORARY TABLES)
  6. Create/append full privileges for an existing database
     and host combination (user has FULL privilege)
  7. Remove all privileges for an existing database and
     host combination.
     (user will have all permission fields set to N)
  0. exit this program
```

This page is licensed: CC BY-SA / Gnu FDL

mariadb-show

Shows the structure of a MariaDB database (databases, tables, columns and indexes).

To get similar functionality, you can use SHOW DATABASES, SHOW TABLES, SHOW COLUMNS, SHOW INDEX and SHOW TABLE STATUS, as well as the Information Schema tables (TABLES, COLUMNS, STATISTICS).

Usage

```
mariadb-show [OPTIONS] [database [table [column]]]
```

The output displays only the names of those databases, tables, or columns for which you have some privileges.

If no database is given then all matching databases are shown. If no table is given, then all matching tables in database are shown. If no column is given, then all matching columns and column types in table are shown.

If the last argument contains a shell or SQL wildcard (`*` , `?` , `%` , or `_`), only what's matched by the wildcard is shown. If a database name contains any underscores, those should be escaped with a backslash (some Unix shells require two) to get a list of the proper tables or columns. The `*` and `?` characters are converted into SQL `%` and `_` wildcard characters. This might cause some confusion when trying to display the columns for a table whose name contains an underscore character (`_`), because `mariadb-show` shows only the table names that match the pattern. To fix this, add an extra `%` last on the command line, as a separate argument.

Options

`mariadb-show` supports the following options:

Option	Description
-c name, –character-sets-dir=name	Directory for character set files.
-C, –compress	Use compression in server/client protocol if both support it.
–count	Show number of rows per table (may be slow for non-MyISAM tables).
[name], –debug[=name]	Output debug log. Typical is `d:t:o,filename`, the default is `d:t:o`.
–debug-check	Check memory and open file usage at exit.
–debug-info	Print some debug info at exit.
–default-auth=name	Default authentication client-side plugin to use.
–default-character-set=name	Set the default character set.
–defaults-extra-file=name	Read the file name after the global files are read. Must be given as the first option.
–defaults-file=name	Only read default options from the given file name. Must be given as the first option.
–defaults-group-suffix=suffix	In addition to the given groups, also read groups with this suffix.
-?, –help	Display help and exit.
-h name, –host=name	Connect to the MariaDB server on the given host.
-k, –keys	Show indexes for table.
–no-defaults	Don’t read default options from any option file. Must be given as the first option.

Option	Description
-p[password], –password[=password]	Password to use when connecting to server. If password is not given, it's solicited on the command line. Specifying a password on the command line should be considered insecure. You can use an option file to avoid giving the password on the command line.
-W, –pipe	On Windows, connect to the server via a named pipe. This option applies only if the server supports named-pipe connections.
–plugin-dir=name	Directory for client-side plugins.
-P num, –port=num	Port number to use for connection or 0 for default to, in order of preference, `my.cnf`, `$MYSQL_TCP_PORT`, `/etc/services`, built-in default (`3306`).
–print-defaults	Print the program argument list and exit. Must be given as the first option.
–protocol=name	The protocol to use for connection (tcp, socket, pipe, memory).
–shared-memory-base-name=name	On Windows, the shared-memory name to use, for connections made using shared memory to a local server. The default value is MYSQL. The shared-memory name is case sensitive. The server must be started with the –shared-memory option to enable shared-memory connections.
-t, –show-table-type	Show table type column, as in SHOW FULL TABLES. The type is `BASE TABLE` or `VIEW`.
-S name, –socket=name	For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use.
–ssl	Enables TLS. TLS is also enabled even without setting this option when certain other TLS options are set. The `--ssl` option does not enable verifying the server certificate by default. In order to verify the server certificate, the user must specify the `--ssl-verify-server-cert` option.
–ssl-ca=name	Defines a path to a PEM file that should contain one or more X509 certificates for trusted Certificate Authorities (CAs) to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option implies the –ssl option.
–ssl-capath=name	Defines a path to a directory that contains one or more PEM files that should each contain one X509 certificate for a trusted Certificate Authority (CA) to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the openssl rehash command. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option is only supported if the client was built with OpenSSL. If the client was built with yaSSL, GnuTLS, or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms. This option implies the –ssl option.
–ssl-cert=name	Defines a path to the X509 certificate file to use for TLS. This option requires that you use the absolute path, not a relative path. This option implies the –ssl option.
–ssl-cipher=name	List of permitted ciphers or cipher suites to use for TLS. This option implies the –ssl option.

Option	Description
–ssl-key=name	Defines a path to a private key file to use for TLS. This option requires that you use the absolute path, not a relative path. This option implies the –ssl option.
–ssl-crl=name	Defines a path to a PEM file that should contain one or more revoked X509 certificates to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL or Schannel. If the client was built with yaSSL or GnuTLS, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms. This option implies the –ssl option.
–ssl-crlpath=name	Defines a path to a directory that contains one or more PEM files that should each contain one revoked X509 certificate to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the openssl rehash command. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL. If the client was built with yaSSL, GnuTLS, or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms. This option implies the –ssl option.
–ssl-verify-server-cert	Enables (or disables) server certificate verification. This option is disabled by default.
-i, –status	Shows a lot of extra information about each table. See the INFORMATION_SCHEMA.TABLES table for more details on the returned information.
–tls-version=name	This option accepts a comma-separated list of TLS protocol versions. A TLS protocol version will only be enabled if it is present in this list. All other TLS protocol versions will not be permitted. See Secure Connections Overview: TLS Protocol Versions for more information.
-u, –user=name	User for login, if not current user.
-v, –verbose	More verbose output; you can use this multiple times to get even more verbose output.
-V, –version	Output version information and exit.

Option Files

In addition to reading options from the command line, `mariadb-show` can also read options from option files. If an unknown option is provided to `mariadb-show` in an option file, then it is ignored.

The following options relate to how MariaDB command line tools handles option files. They must be given as the first argument on the command line:

Option	Description
–print-defaults	Print the program argument list and exit.
–no-defaults	Don't read default options from any option file.
–defaults-file=#	Only read default options from the given file #.
–defaults-extra-file=#	Read this file after the global files are read.
–defaults-group-suffix=#	In addition to the default option groups, also read option groups with this suffix.

`mariadb-show` is linked with MariaDB Connector/C. However, MariaDB Connector/C does not handle the parsing of option files for this client. This is performed by the server option file parsing code. See MDEV-19035 for more information.

Option Groups

`mariadb-show` reads options from the following option groups from option files:

Group	Description
[mysqlshow]	Options read by `mysqlshow`, which includes both MariaDB Server and MySQL Server.
[mariadb-show]	Options read by mariadb-show.
[client]	Options read by all MariaDB and MySQL client programs, which includes both MariaDB and MySQL clients.
[client-server]	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients.
[client-mariadb]	Options read by all MariaDB client programs.

Examples

Getting a list of databases:

```
bin/mariadb-show
+--------------------+
|     Databases      |
+--------------------+
| information_schema |
| test               |
+--------------------+
```

Getting a list of tables in the `test` database:

```
bin/mariadb-show test
Database: test
+---------+
| Tables  |
+---------+
| author  |
| book    |
| city    |
| country |
+---------+
```

Getting a list of columns in the `test`.`book` table:

```
bin/mariadb-show test book
Database: test  Table: book
+-----------+-----------------------+-------------------+------+-----+---------+----------------+--------
-----------------------+---------+
| Field     | Type                  | Collation         | Null | Key | Default | Extra          |
Privileges                     | Comment |
+-----------+-----------------------+-------------------+------+-----+---------+----------------+--------
-----------------------+---------+
| id        | mediumint(8) unsigned |                   | NO   | PRI |         | auto_increment |
select,insert,update,references |         |
| title     | varchar(200)          | latin1_swedish_ci | NO   |     |         |                |
select,insert,update,references |         |
| author_id | smallint(5) unsigned  |                   | NO   | MUL |         |                |
select,insert,update,references |         |
+-----------+-----------------------+-------------------+------+-----+---------+----------------+--------
-----------------------+---------+
```

mariadb-plugin

`mariadb-plugin` is a tool for enabling or disabling plugins.

The client was previously called `mysql_plugin`, and can still be accessed under this name, via a symlink in Linux, or an alternate binary in Windows.

It is a command line alternative to the INSTALL PLUGIN and UNINSTALL PLUGIN statements, and the `--plugin-load option` to mariadbd.

`mariadb-plugin` must be run while the server is offline, and works by adding or removing rows from the mysql.plugin table.

`mariadb-plugin` basically has two use cases:

1. To add a plugin even before the first real server startup.
2. To remove a plugin that crashes the server on startup.

For the installation use case, adding a plugin-load-add entry to `my.cnf` or in a separate include option file is a better alternative. In case of a plugin loaded via a `mysql.plugin` crashing the server, uninstalling the plugin with the help of `mariadb-plugin` can be the only viable action, though.

Usage

```
mariadb-plugin [options] <plugin> ENABLE|DISABLE
```

`mariadb-plugin` expects to find a configuration file that indicates how to configure the plugins. The configuration file has, by default, the same name as the plugin, with an `.ini` extension:

```
mariadb-plugin crazyplugins ENABLE
```

Here, `mariadb-plugin` looks for a file called `crazyplugins.ini` :

```
crazyplugins
crazyplugin1
crazyplugin2
crazyplugin3
```

The first line should contain the name of the library object file, with no extension. The other lines list the names of the components. Each value should be on a separate line. The `#` character at the start of a line indicates a comment.

Options

The following options can be specified on the command line, while some can be specified in the `[mysqld]` group of any option file. For options specified in a `[mysqld]` group, only the `--basedir`, `--datadir`, and `--plugin-dir` options can be used — the rest are ignored.

Option	Description
-b, –basedir=name	The base directory for the server.
-d, –datadir=name	The data directory for the server.
-?, –help	Display help and exit.
-f, –my-print-defaults=name	Path to my_print_defaults executable. Example: /source/temp11/extra
-m, –mysqld=name	Path to mysqld executable. Example: /sbin/temp1/mysql/bin
-n, –no-defaults	Do not read values from configuration file.
-p, –plugin-dir=name	The plugin directory for the server.

Option	Description
-i, –plugin-ini=name	Read plugin information from configuration file specified instead of from /<plugin_name>.ini.
-P, –print-defaults	Show default values from configuration file.
-v, –verbose	More verbose output; you can use this multiple times to get even more verbose output.
-V, –version	Output version information and exit.

mariadb-report

`mariadb-report` makes a friendly report of important MariaDB status values.

Previously, the client was called `mysqlreport`. It can still be accessed under this name, via a symlink in Linux, or an alternate binary in Windows.

`mariadb-report` makes a report of nearly every status value from SHOW STATUS. Unlike `SHOW STATUS`, which simply dumps over 100 values to the screen in one long list, `mariadb-report` interprets and formats the values, and presents the basic values and many more inferred values in a human-readable format. Numerous example reports are available in this report: hackmysql.com/mysqlreport, archived here.

The benefit of mariadb-report is that it allows you to very quickly see a wide array of performance indicators for your MariaDB server which would otherwise need to be calculated by hand from all the various `SHOW STATUS` values. For example, the Index Read Ratio is an important value but it's not present in `SHOW STATUS`; it's an inferred value (the ratio of `Key_reads` to `Key_read_requests`).

This documentation outlines all the command line options in `mariadb-report`, most of which control which reports are printed. This document does not address how to interpret these reports; that topic is covered in the document Guide To Understanding mysqlreport, archived here.

Usage

```
mariadb-report [options]
```

mariadb-report options

Technically, command line options are in the form `--option`, but `-option` works, too. All options can be abbreviated if the abbreviation is unique. For example, option `--host` can be abbreviated to `--ho` but not `--h` because `--h` is ambiguous: it could mean `--host` or `--help`.

Option	Description
–all	Equivalent to `--dtq --dms --com 3 --sas --qcache`. (Note that `--tab` is not invoked by `--all`.)

Option	Description
–com N	Print top N number of non-DMS Com_ status values in descending order (after DMS in Questions report). If N is not given, default is 3. Such non-DMS Com_ values include Com_change_db, Com_show_tables, Com_rollback, etc.
–dms	Print Data Manipulation Statements (DMS) report (under DMS in Questions report). DMS are those from the Data Manipulation section. mariadb-report considers only SELECT, INSERT, REPLACE, UPDATE, and DELETE. Each DMS is listed in descending order by count.
–dtq	Print Distribution of Total Queries (DTQ) report (under Total in Questions report). Queries (or Questions) can be divided into four main areas: `DMS` (see `--dms`), `Com_` (see `--com`), `COM_QUIT` (see `COM_QUIT` and Questions, archived here), and `Unknown`. `--dtq` lists the number of queries in each of these areas in descending order.
–email *address*	After printing the report to screen, email the report to *address*. This option requires sendmail in `/usr/sbin/`, therefore it does not work on Windows. `/usr/sbin/sendmail` can be a symlink to qmail, or any MTA (mail transfer agent) that emulates sendmail's `-t` command line option and operation. The FROM: field is "mariadb-report", SUBJECT: is "MySQL status report".
–flush-status	Execute a FLUSH STATUS after generating the reports. If you do not have permissions in MariaDB to do this an error from `DBD::mysql::st` is printed after the reports.
–help	Output help information and exit.
–host ADDRESS	Host address.
–infile *file*	Instead of getting SHOW STATUS values from MariaDB, read values from *file*. *file* is often a copy of the output of `SHOW STATUS` including formatting characters (+, -). `mariadb-report` expects *file* to have the format "*value* number", where *value* is only alpha and underscore characters (A-Z and _) and number is a positive integer. Anything before, between, or after value and number is ignored. mariadb-report also needs the following MariaDB server variables: version, table_cache, max_connections, key_buffer_size, query_cache_size. These values can be specified in `INFILE` in the format "name = value", where name is one of the aforementioned server variables and value is a positive integer with or without a trailing M and possible periods (for version). For example, to specify an 18M key_buffer_size, specify `key_buffer_size = 18M`. Or, for a 256 byte table_cache, specify `table_cache = 256`. The M implies Megabytes, so 18M means 18,874,368. If these server variables are not specified, the following defaults are used (respectively) which may cause strange values to be reported: 0.0.0, 64, 100, 8M, 0.
–no-mycnf	Makes `mariadb-report` not read `/.my.cnf` which it does by default otherwise. `--user` and `--password` always override values from `/.my.cnf`.
–outfile *file*	After printing the report to screen, print the report to *file* too. Internally, `mariadb-report` always writes the report to a temporary file first: `/tmp/mysqlreport`.PID on *nix, c:sqlreport. PID on Windows (PID is the script's process ID). Then it prints the temp file to screen. Then if –outfile is specified, the temp file is copied to `OUTFILE`. After `--email` (above), the temp file is deleted.
–password	`--password` can take the password on the command line, like `--password FOO`. Using `--password` without an argument causes `mariadb-report` to prompt for a password.
–port *port*	Port number.

Option	Description
–qcache	Print Query Cache report.
–sas	Print report for Select_ and Sort_ status values (after Questions report). See MySQL Select and Sort Status Variables, archived here.
–socket *socket*	For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use.
–tab	Print Threads, Aborted, and Bytes status reports (after Created temp report). The Threads report reports on all Threads_ status values.
–user *username*	Username.

This page is licensed: CC BY-SA / Gnu FDL

mariadb-find-rows

`mariadb-find-rows` reads files containing SQL statements and extracts statements that match a given regular expression or that contain USE db_name or SET statements.

Previously, the client was called `mysql_find_rows`. It can still be accessed under this name, via a symlink in Linux, or an alternate binary in Windows.

The utility was written for use with update log files (as used prior to MySQL 5.0), and as such expects statements to be terminated with semicolon (`;`) characters. It may be useful with other files that contain SQL statements, as long as statements are terminated with semicolons.

Usage

```
mariadb-find-rows [options] [file_name ...]
```

Each file_name argument should be the name of file containing SQL statements. If no file names are given, the tool reads from `stdin` (standard input).

Options

`mariadb-find-rows` supports the following options:

Option	Description
–help, –Information	Display help and exit.
–regexp=*pattern*	Display queries that match *pattern*.
–rows=N	Quit after displaying *N* queries.
–skip-use-db	Do not include USE db_name statements in the output.
–start_row=*N*	Start output from this row (first row is `1`).

Examples

```
mariadb-find-rows --regexp=problem_table --rows=20 < update.log
mariadb-find-rows --regexp=problem_table  update-log.1 update-log.2
```

This page is licensed: CC BY-SA / Gnu FDL

mariadb-tzinfo-to-sql

`mariadb-tzinfo-to-sql` is a tool used to load time zones on systems that have a zoneinfo database to load the time zone tables (time_zone, time_zone_leap_second, time_zone_name, time_zone_transition and time_zone_transition_type) into the mysql database.

Previously, the client was called `mysql_tzinfo_to_sql`. It can still be accessed under this name, via a symlink in Linux, or an alternate binary in Windows.

Most Linux, Mac OS X, FreeBSD and Solaris systems will have a zoneinfo database - Windows does not. The database is commonly found in the `/usr/share/zoneinfo` directory, or, on Solaris, the `/usr/share/lib/zoneinfo` directory.

Usage

`mariadb-tzinfo-to-sql` can be called in several ways. The output is usually passed straight to the mariadb client for direct loading in the mysql database.

```
shell> mariadb-tzinfo-to-sql timezone_dir
shell> mariadb-tzinfo-to-sql timezone_file timezone_name
shell> mariadb-tzinfo-to-sql --leap timezone_file
```

Resetting timezone tables

If there is a need to reset the timezone to the default, to before using `mariadb-tzinfo-to-sql`, one can do that by executing:

```
TRUNCATE TABLE mysql.time_zone;
TRUNCATE TABLE mysql.time_zone_name;
TRUNCATE TABLE mysql.time_zone_transition;
TRUNCATE TABLE mysql.time_zone_transition_type;
TRUNCATE TABLE mysql.time_zone_leap_second;
```

The old timezone values is in effect until the server is restarted.

Examples

Most commonly, the whole directory is passed:

```
shell> mariadb-tzinfo-to-sql /usr/share/zoneinfo | mariadb -u root mysql
```

Load a single time zone file, `timezone_file`, corresponding to the time zone called `timezone_name` :

```
shell> mariadb-tzinfo-to-sql timezone_file timezone_name | mariadb -u root mysql
```

A separate command for each time zone and time zone file the server needs is required.

To account for leap seconds, use:

```
shell> mariadb-tzinfo-to-sql --leap timezone_file | mariadb -u root mysql
```

After populating the time zone tables, you should usually restart the server so that the new time zone data are correctly loaded.

This page is licensed: CC BY-SA / Gnu FDL

mariadb-waitpid

`mariadb_waitpid` is a utility for terminating processes.

> **Note:**
>
> It runs on Unix-like systems, making use of the `kill()` system call.

Previously, the client was called `mysql_waitpid`. It can still be accessed under this name, via a symlink in Linux, or an alternate binary in Windows.

Usage

```
mariadb-waitpid [options] pid time
```

Description

`mariadb-waitpid` sends signal `0` to the process *pid* and waits up to *time* seconds for the process to terminate. *pid*. *time* must be positive integers.

Returns `0` if the process terminates in time or does not exist, and `1` otherwise.

Signal `1` is used if the `kill()` system call cannot handle signal `0`.

Options

Option	Description
-?, –help	Display help and exit.
-I, –help	Synonym for `-?`.
-v, –verbose	Be more verbose. Give a warning, if kill can't handle signal `0`.
-V, –version	Print version information and exit.

This page is licensed: CC BY-SA / Gnu FDL

my_print_defaults

`my_print_defaults` displays the options from option groups of option files. It is useful to see which options a particular tool will use.

Output is one option per line, displayed in the form in which they would be specified on the command line.

Usage

```
my_print_defaults [OPTIONS] [groups]
```

Options

Option	Description
-c, –config-file=*name*	Deprecated, use `--defaults-file` instead. Name of config file to read; if no extension is given, default extension (`.ini` or `.cnf`) are added.

Option	Description
-d, –debug[=#]	In debug versions, write a debugging log. A typical debug_options string is `d:t:o,file_name`. The default is `d:t:o,/tmp/my_print_defaults.trace`.
-c, –defaults-file=*name*	Like `--config-file`, except if it is the first option. In that case, read this file only, do not read global or per-user config files; should be the first option. Removed in MariaDB 10.8.
-e, –defaults-extra-file=*name*	Read this file after the global config file and before the config file in the users home directory; should be the first option. Removed in MariaDB 10.8.
-g, –defaults-group-suffix=*name*	In addition to the given groups, read also groups with this suffix. Removed in MariaDB 10.8.
-e, –extra-file=*name*	Deprecated. Synonym for `--defaults-extra-file`.
–mariadbd	Read the same set of groups that the mariadbd server does. Available from MariaDB 10.11.3.
–mysqld	Read the same set of groups that the mysqld server does.
-n, –no-defaults	Return an empty string (useful for scripts).
?, –help	Display this help message and exit.
-v, –verbose	Increase the output level.
-V, –version	Output version information and exit.

Examples

```
my_print_defaults --defaults-file=example.cnf client client-server mysql
```

mariadb-check reads from the `[mariadb-check]` and `[client]` sections in option files, so the following would display the mariadb-check options.

```
my_print_defaults mariadb-check client
```

This page is licensed: CC BY-SA / Gnu FDL

mariadb-embedded

`mariadb-embedded` is a mariadb client, statically linked to `libmariadbd`, the embedded server.

Previously, the client was called `mysql_embedded`. It can still be accessed under this name, via a symlink in Linux, or an alternate binary in Windows.

Upon execution, an embedded MariaDB server is instantiated, and you can execute statements just as you would using the normal mariadb client, using the same options.

> **Important:**
>
> Do not run *mariadb-embedded* using the same database as a running MariaDB server!

Examples

```
sudo mariadb-embedded -e 'select user, host, password from mysql.user where user="root"'
+------+-----------+-------------------------------------------+
| user | host      | password                                  |
+------+-----------+-------------------------------------------+
| root | localhost | *196BDEDE2AE4F84CA44C47D54D78478C7E2BD7B7 |
| root | db1       | *196BDEDE2AE4F84CA44C47D54D78478C7E2BD7B7 |
| root | 127.0.0.1 | *196BDEDE2AE4F84CA44C47D54D78478C7E2BD7B7 |
| root | ::1       | *196BDEDE2AE4F84CA44C47D54D78478C7E2BD7B7 |
+------+-----------+-------------------------------------------+
```

Sending options with `--server-arg`:

```
sudo mariadb-embedded --server-arg='--skip-innodb'
  --server-arg='--default-storage-engine=myisam'
  --server-arg='--log-error=/tmp/mysql.err'
  -e 'select user, host, password from mysql.user where user="root"'
+------+-----------+-------------------------------------------+
| user | host      | password                                  |
+------+-----------+-------------------------------------------+
| root | localhost | *196BDEDE2AE4F84CA44C47D54D78478C7E2BD7B7 |
| root | db1       | *196BDEDE2AE4F84CA44C47D54D78478C7E2BD7B7 |
| root | 127.0.0.1 | *196BDEDE2AE4F84CA44C47D54D78478C7E2BD7B7 |
| root | ::1       | *196BDEDE2AE4F84CA44C47D54D78478C7E2BD7B7 |
+------+-----------+-------------------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

perror

perror is a utility that displays descriptions for system or storage engine error codes.

See MariaDB Error Codes for a full list of MariaDB error codes, and Operating System Error Codes for a list of Linux and Windows error codes.

Usage

```
perror [OPTIONS] [ERRORCODE [ERRORCODE...]]
```

If you need to describe a negative error code, use `--` before the first error code to end the options.

Options

Option	Description
-?, –help	Display help and exit.
-I, –info	Synonym for –help.
-s, –silent	Only print the error message.
-v, –verbose	Print error code and message (default). (Defaults to on; use –skip-verbose to disable.)
-V, –version	Displays version information and exits.

Examples

System error code:

```
shell> perror 96
OS error code  96:  Protocol family not supported
```

MariaDB/MySQL error code:

```
shell> perror 1005 1006
MySQL error code 1005 (ER_CANT_CREATE_TABLE): Can't create table %`s.%`s (errno: %M)
MySQL error code 1006 (ER_CANT_CREATE_DB): Can't create database '%-.192s' (errno: %M)
```

```
shell> perror --silent 1979
You are not owner of query %lu
```

This page is licensed: CC BY-SA / Gnu FDL

replace

Description

The `replace` utility program changes strings in place in files or on the standard input. Invoke replace in one of the following ways:

```
shell> replace from to [from to] ... -- file_name [file_name] ...
shell> replace from to [from to] ... < file_name
```

`from` represents a string to look for, and `to` represents its replacement. There can be one or more pairs of strings.

A from-string can contain these special characters:

Character	Description
^	Match start of line.
$	Match end of line.
\b	Match space-character, start of line or end of line. For an end `\b`, the next replace starts looking at the end space character ( ). A `\b` alone in a string matches only a space character.

Use the `--` option to indicate where the string-replacement list ends and the file names begin. Any file named on the command line is modified in place, so you may want to make a copy of the original before converting it. `replace` prints a message indicating which of the input files it actually modifies.

If the `--` option is not given, `replace` reads standard input and writes to `stdout` (standard output).

`replace` uses a finite state machine to match longer strings first. It can be used to swap strings. For example, the following command swaps “a” and “b” in the given files, *file1 and file2*:

```
shell> replace a b b a -- file1 file2 ...
```

Options

`replace` supports the following options:

Option	Description
-?, -I	Display a help message and exit.
-#debug_options	Enable debugging.
-s	Silent mode. Print less information about what the program does.
-v	Verbose mode. Print more information about what the program does.
-V	Display version information and exit.

This page is licensed: CC BY-SA / Gnu FDL

resolve_stack_dump

`resolve_stack_dump` is a tool that resolves numeric stack strace dumps into symbols.

Usage

```
resolve_stack_dump [OPTIONS] symbols-file [numeric-dump-file]
```

The symbols-file should include the output from: `nm --numeric-sort mariadbd`. The numeric-dump-file should contain a numeric stack trace from mariadbd. If the numeric-dump-file is not given, the stack trace is read from stdin.

Options

Option	Description
-h, –help	Display this help and exit.
-V, –version	Output version information and exit.
-s, –symbols-file=*name*	Use specified symbols file.
-n, –numeric-dump-file=*name*	Read the dump from specified file.

This page is licensed: CC BY-SA / Gnu FDL

Aria Clients and Utilities

See aria_chk.

Check, repair, optimize, and report information about Aria tables with the aria_chk command-line tool.

See aria_pack.

Compress Aria tables into read-only form that is typically 40 to 70 percent smaller with aria_pack.

See aria_read_log.

Display and apply records from the Aria transaction log with the aria_read_log tool.

This page is licensed: CC BY-SA / Gnu FDL

aria_chk

`aria_chk` is used to check, repair, optimize, sort and get information about Aria tables.

With the MariaDB server, you can use CHECK TABLE,REPAIR TABLE and OPTIMIZE TABLE to do similar things.

> **Important:**
>
> Note: `aria_chk` should not be used when MariaDB is running. MariaDB Server assumes that no one is changing the tables it's using.

Usage

```
aria_chk [OPTIONS] aria_tables[.MAI]
```

Aria table information is stored in 2 files: the `.MAI` file contains base table information and the index and the `.MAD` file contains the data.`aria_chk` takes one or more `.MAI` files as arguments.

The following groups are read from the my.cnf files:

- `[maria_chk]`
- `[aria_chk]`

Options and Variables

Global Options

The following options to handle option files may be given as the first argument:

Option	Description
–print-defaults	Print the program argument list and exit.

Option	Description
–no-defaults	Don't read default options from any option file.
–defaults-file=#	Only read default options from the given file #.
–defaults-extra-file=#	Read this file after the global files are read.

Main Arguments

Option	Description
-#, –debug=…	Output debug log. Often this is `d:t:o,filename`.
-H, –HELP	Display this help and exit.
-?, –help	Display this help and exit.
–datadir=path	Path for control file (and logs if the `--logdir` option is not used).
–ignore-control-file	
–logdir=path	Path for log files.
–require-control-file	Abort if we can't find/read the `maria_log_control` file.
-s, –silent	Only print errors. You can use two `-s` options to make `aria_chk` very silent.
-t, –tmpdir=path	Path for temporary files. Multiple paths can be specified, separated by colon (`:`) on Unix or semicolon (`;`) on Windows. They are used in a round-robin fashion.
-v, –verbose	Print more information. This can be used with `--description` and `--check`. Use many `-v` options for more verbosity.
-V, –version	Print version and exit.
-w, –wait	Wait if table is locked.

Check Options

`-` `-check` is the default action for `aria_chk`:

Option	Description
-c, –check	Check table for errors.
-e, –extend-check	Check the table *very* thoroughly. Only use this in extreme cases, as `aria_chk` should normally be able to find out if the table is okay, even without this switch.
-F, –fast	Check only tables that haven't been closed properly.
-C, –check-only-changed	Check only tables that have changed since last check.
-f, –force	Restart with `-r` if there are any errors in the table. States is updated as with `--update-state`.
-i, –information	Print statistics information about table that is checked.
-m, –medium-check	Faster than extend-check, and finds 99.99% of all errors. Should be good enough for most cases.
-U, –update-state	Mark tables as crashed if any errors were found and clean if check didn't find any errors but table was marked as 'not clean' before. This allows one to get rid of warnings like 'table not properly closed'. If table was updated, update also the timestamp for when the check was made. This option is on by default! Use –skip-update-state to disable.

Option	Description
-T, –read-only	Don't mark table as checked.

Recover (Repair) Options

When using `--recover` or `--safe-recover'` , these options are available:

Option	Description
-B, –backup	Make a backup of the `.MAD` file as *`filename`* `-time.BAK'` .
–correct-checksum	Correct checksum information for table.
-D, –data-file-length=#	Max length of data file (when recreating data file when it's full).
-e, –extend-check	Try to recover every possible row from the data file Normally this will also find a lot of garbage rows; Don't use this option if you are not totally desperate.
-f, –force	Overwrite old temporary files.
-k, –keys-used=#	Tell MariaDB to update only some specific keys. # is a bit mask of which keys to use. This can be used to get faster inserts.
–max-record-length=#	Skip rows bigger than this if `aria_chk` can't allocate memory to hold it.
-r, –recover	Can fix almost anything except unique keys that aren't unique.
-n, –sort-recover	Forces recovering with sorting even if the temporary file would be very big.
-p, –parallel-recover	Uses the same technique as `-r` and `-n` , but creates all the keys in parallel, in different threads.
-o, –safe-recover	Uses an old recovery method, which is slower than using `-r` but can handle a couple of cases where `-r` reports that it can't fix the data file.
–transaction-log	Log repair command to transaction log. This is needed if one wants to use the `maria_read_log` option to repeat the repair.
–character-sets-dir=…	Directory where character sets are.
–set-collation=name	Change the collation used by the index.
-q, –quick	
-u, –unpack	Unpack file packed with aria_pack.

Other Options

Option	Description
-a, –analyze	Analyze distribution of keys. Will make some joins in MariaDB faster. You can check the calculated distribution by using `--description --verbose`` *`table_name`* '.
–stats_method=name	Specifies how index statistics collection code should treat NULLs. Possible values of name are "nulls_unequal" (default for 4.1/5.0), "nulls_equal" (emulate 4.0), and "nulls_ignored".
-d, –description	Prints some information about table.
-A, –set-auto-increment[=value]	Force auto_increment to start at this or higher value If no value is given, then sets the next auto_increment value to the highest used value for the auto key + 1.

Option	Description
-S, –sort-index	Sort index blocks. This speeds up ‘read-next’ in applications.
-R, –sort-records=#	Sort records according to an index. This makes your data much more localized and may speed up things (It may be VERY slow to do a sort the first time!).
-b, –block-search=#	Find a record, a block at given offset belongs to.
-z, –zerofill	Remove transaction id’s from the data and index files and fills empty space in the data and index files with zeroes. Zerofilling makes it possible to move the table from one system to another without the server having to do an automatic zerofill. It also allows one to compress the tables better if one want to archive them.
–zerofill-keep-lsn	Like –zerofill but does not zero out LSN of data/index pages.

Variables

Option	Description
page_buffer_size	Size of page buffer. Used by `--safe-repair`.
read_buffer_size	Read buffer size for sequential reads during scanning.
write_buffer_size	Write buffer size for sequential writes during repair of fixed size or dynamic size rows.
sort_buffer_size	Size of sort buffer. Used by `--recover`.
sort_key_blocks	Internal buffer for sorting keys. Do not use!

Examples

The main usage of `aria_chk` is a fast check of all Aria tables in your system. This is faster than doing it in MariaDB, as you can allocate all free memory to the buffers.

Assuming you have a bit more than 2G free memory, the following commands, run in the MariaDB data directory, check all your tables and repairs only those that have an error:

```
aria_chk --check --sort_order --force --sort_buffer_size=1G */*.MAI
```

To optimize all your tables, run this command (the `--zerofill` option is used here to fill up empty space with `\0` which can speed up compressed backups):

```
aria_chk --analyze --sort-index --page_buffer_size=1G --zerofill */*.MAI
```

In case you have a serious problem and have to use `--safe-recover`, run this command:

```
aria_chk --safe-recover --zerofill --page_buffer_size=2G */*.MAI
```

This page is licensed: CC BY-SA / Gnu FDL

aria_pack

`aria_pack` is a tool for compressing Aria tables. The resulting tables are read-only, and usually about 40% to 70% smaller.

`aria_pack` is run as follows:

```
aria_pack [options] file_name [file_name2...]
```

The file name is the `.MAI` index file. The extension can be omitted, although keeping it permits wildcards, for instance to compress all the files, such as:

```
aria_pack *.MAI
```

`aria_pack` compresses each column separately. This means, when the resulting data is read, only the individual rows and columns required need to be decompressed, allowing for quicker reading.

Once a table has been packed, use aria_chk -rq (the quick and recover options) to rebuild its indexes.

Options

The following variables can be set as command line options to `aria_pack`, or set in the `[ariapack]` section in your my.cnf file:

Option	Description
-b, –backup	Make a backup of the table as *`table_name`* `.OLD`.
–character-sets-dir=*name*	Directory where character sets are located.
-h, –datadir	
-#, –debug[=name]	Output debug log. Often this is `d:t:o,filename`.
-?, –help	Display help and exit.
-f, –force	Force packing of table even if it gets bigger or if a temporary file exists.
–ignore-control-file	
-j, –join=*name*	Join all given tables into *name*. All tables must have identical layouts.
–require-control-file	
-s, –silent	Only write output when an error occurs.
-t, –test	Don’t pack table, only test packing it.
-T, –tmpdir=name	Use temporary directory to store temporary table.
-v, –verbose	Write info about progress and packing result. Use multiple `-v` options for more verbosity.
-V, –version	Output version information and exit.
-w, –wait	Wait and retry if table is in use.

Unpacking

To unpack a table compressed with aria_pack, use the aria_chk -u option.

Example

```
> aria_pack /my/data/test/posts
Compressing /my/data/test/posts.MAD: (1690 records)
- Calculating statistics
- Compressing file
37.71%
> aria_chk -rq --ignore-control-file /my/data/test/posts
- check record delete-chain
- recovering (with keycache) Aria-table '/my/data/test/posts'
Data records: 1690
State updated
```

- FLUSH TABLES FOR EXPORT

- myisamchk

This page is licensed: CC BY-SA / Gnu FDL

aria_read_log

`aria_read_log` is a tool for displaying and applying log records from an Aria transaction log.

> **Warning:**
>
> Aria is compiled without `-DIDENTICAL_PAGES_AFTER_RECOVERY` which means that the table files are not byte-to-byte identical to files created during normal execution. This should be okay, except for test scripts that try to compare files before and after recovery.

Usage

```
aria_read_log OPTIONS
```

As an option, you need to use at least one of `-d` or `-a`.

Options

The following variables can be set while passed as command line options to `aria_read_log`, or set in the `[aria_read_log]` section in your my.cnf file.

Option	Description
-a, –apply	
–character-sets-dir=*name*	Directory where character sets are.
-c, –check	Used with the `--display-only` option, check if record is fully readable (for debugging).
-?, –help	Display help and exit.
-d, –display-only	Display brief info read from records' header.
-e, –end-lsn=#	Stop applying at this lsn. If end-lsn is used, UNDO operations are not be applied.
-h, –aria-log-dir-path=*name*	Path to the directory where to store transactional log.
-P, –page-buffer-size=#	The size of the buffer used for index blocks of Aria tables.
-l, –print-log-control-file	Print the content of the `aria_log_control_file`.
-o, –start-from-lsn=#	Start reading log from this lsn.
-C, –start-from-checkpoint	Start applying from last checkpoint.
-s, –silent	Print less information during apply/undo phase.
-T, –tables-to-redo=*name*	List of comma-separated tables that we should apply REDO on. Use this if you only want to recover some tables.
-t, –tmpdir=name	Path for temporary files. Multiple paths can be specified, separated by colon (`:`).
–translog-buffer-size=#	The size of the buffer used for transaction log of Aria tables.
-u, –undo	Apply UNDO records to tables. Disable with `--disable-undo`. Defaults to on; use `--skip-undo` to disable.
-v, –verbose	Print more information during apply/undo phase.
-V, –version	Print version and exit.

Backup, Restore and Import Clients

See mariadb-dump.

Complete MariaDB backup and recovery guide. Complete resource for backup methods, mariabackup usage, scheduling, and restoration for production use.

See mariadb-hotcopy.

Quickly back up MyISAM and Aria tables by copying table files with the mariadb-hotcopy Perl script (formerly mysqlhotcopy).

See mariadb-import.

Complete mariadb-import reference: load tables from text files, –fields-terminated-by delimiter, –local file option, and –parallel/-j processing.

See dbForge Studio.

dbForge Studio is a proprietary third-party tool, not included with MariaDB, for backup, restore, and data export and import.

This page is licensed: CC BY-SA / Gnu FDL

mariadb-dump

The `mariadb-dump` client is a backup program originally written by Igor Romanenko.

> **Note:**
>
> Previously, the client used to be called `mysqldump`, and can still be accessed under this name, via a symlink in Linux, or an alternate binary in Windows. From MariaDB 11.0, the symlink `mysqldump` is deprecated and removed from the `mariadb` Docker Official Image.

`mariadb-dump` generates a command at the beginning of the dump to enable sandbox mode. This command cannot be interpreted by earlier versions of the `mariadb` command-line client or by the MySQL command-line client `mysql` – an error is thrown if used against client versions that do not support it. This does not affect other methods of importing the data.

`mariadb-dump` is used to dump a database or a collection of databases for backup, or transferring data to another database server (not necessarily MariaDB or MySQL). The dump contains SQL statements to create databases, tables, table data, and more. It can also be used to generate files in CSV, XML, or other formats that use delimiters.

> **Note:**
>
> If you are doing a backup on the server and all your tables are MyISAM tables, consider using mariadb-hotcopy instead, because it can accomplish faster backups and faster restores.

`mariadb-dump` dumps trigger along with tables, as these are part of the table definition. However, stored procedures, views, and events are not dumped, and need extra parameters to be recreated explicitly (for example, `--routines` and `--events`). Procedures and functions are also part of the system tables (for example, mysql.proc).

`mariadb-dump` supports the enhancements for START TRANSACTION WITH CONSISTENT SNAPSHOT.

Performance

`mariadb-dump` doesn't consume much CPU – by default, it uses a single thread. This method is good for a heavily loaded server.

Disk input/output per second (IOPS) can, however, increase for multiple reasons. When backing up on the same device as the database, this produces unnecessary random IOPS. The dump is done sequentially, on a per-table basis, causing a full table scan and many buffer page misses on tables that are not fully cached in memory.

> **Warning:**
>
> It's recommended that you back up from a network location to remove disk IOPS on the database server, but it is vital to use a separate network card to keep network bandwidth available for regular traffic.

Although `mariadb-dump` by default preserves your resources for regular spindle disks and low-core hardware, this doesn't mean that concurrent dumps cannot benefit from hardware architecture like SAN, flash storage, or low write workload. The backup time would benefit from a tool such as MyDumper.

Usage

There are four general ways to invoke `mariadb-dump`:

```
shell> mariadb-dump [options] db_name [tbl_name ...]
shell> mariadb-dump [options] --databases db_name ...
shell> mariadb-dump [options] --all-databases
shell> mariadb-dump [options] --system=[option_list]
```

If you do not name any tables after specifying `db_name`, or if you use the `--databases` or `--all-databases` option, entire databases are dumped.

`mariadb-dump` does not dump the `INFORMATION_SCHEMA` (or `PERFORMANCE_SCHEMA`, if enabled) database by default. MariaDB dumps the `INFORMATION_SCHEMA` if you name it explicitly on the command line, although you must also use the `--skip-lock-tables` option.

To see a list of the options your version of `mariadb-dump` supports, execute `mariadb-dump --help`.

Row by Row vs. Buffering

`mariadb-dump` can retrieve and dump table contents row by row, or it can retrieve the entire content from a table and buffer it in memory before dumping it. Buffering in memory can be a problem if you are dumping large tables. To dump tables row by row, use the `--quick` option (or `--opt`, which enables `--quick`). The `--opt` option (and hence `--quick`) is enabled by default, so to enable memory buffering, use `--skip-quick`.

mysql.transaction_registry_table

`mariadb-dump` includes logic to cater for the mysql.transaction_registry table.

Generated Columns

From MariaDB 13.1, `mariadb-dump` no longer writes the computed values of generated columns into the `INSERT` statements it produces. The values are redundant, because the server recalculates them when the dump is reloaded.

Given this table:

```
CREATE TABLE t1 (pk INTEGER, a INTEGER, b INTEGER, c VARCHAR(16),
                 sum INTEGER GENERATED ALWAYS AS (a+b) VIRTUAL,
                 sub VARCHAR(4) GENERATED ALWAYS AS (SUBSTRING(c, 1, 4)) VIRTUAL);
```

by default a generated column keeps its position in the row, and its value is written as `DEFAULT`:

```
INSERT INTO `t1` VALUES
(1,11,12,'oneone',DEFAULT,DEFAULT),
(2,21,22,'twotwo',DEFAULT,DEFAULT);
```

With `--complete-insert`, generated columns are left out of both the column list and the values:

```
INSERT INTO `t1` (`pk`, `a`, `b`, `c`) VALUES (1,11,12,'oneone'),
(2,21,22,'twotwo');
```

An INVISIBLE column enables `--complete-insert` for that table, so the dump gets a column list even when the option is not given. Generated columns are then only left out from the first `INVISIBLE` column onward: a generated column declared *before* it stays in the column list, with its value written as `DEFAULT`. Given this table:

```
CREATE TABLE t4 (pk INTEGER, a INTEGER,
                 b INTEGER GENERATED ALWAYS AS (a+1),
                 c INTEGER INVISIBLE,
                 d INTEGER GENERATED ALWAYS AS (a+pk));
```

`b` precedes the `INVISIBLE` column and is kept, while `d` follows it and is omitted:

```
INSERT INTO `t4` (`pk`, `a`, `b`, `c`) VALUES (1,2,DEFAULT,10),
(4,5,DEFAULT,20);
```

Passing `--complete-insert` explicitly leaves out every generated column, whatever its position.

If every column in a table is generated, `--complete-insert` writes an empty column list, which preserves the row count:

```
INSERT INTO `t5` () VALUES (),
(),
();
```

> **Note:**
>
> This applies to the SQL output only. The `--xml` output is unchanged, and still contains generated columns with their computed values. `--tab` and `--dir` are also unaffected, because the server writes those data files with `SELECT ... INTO OUTFILE`. System-versioned `row_start` and `row_end` columns are not treated as generated columns.

Old Versions of MySQL

If you are using a recent version of `mariadb-dump` to generate a dump to be reloaded into a very old MySQL server, you should *not* use the `--opt` or `--extended-insert` option. Use `--skip-opt` instead.

Options

`mariadb-dump` supports the following options:

Scope

–all

Deprecated. Use –create-options instead.

-A, –all-databases

Dump all the databases. This is the same as `--databases` with all databases selected.

-Y, –all-tablespaces

Dump all the tablespaces.

-y, –no-tablespaces

Do not dump any tablespace information.

Other Options

–add-drop-database

Add a DROP DATABASE before each create. Typically used in conjunction with the `--all-databases` or `--databases` option, because no CREATE DATABASE statements are written, unless one of those options is specified.

–add-drop-table

Add a DROP TABLE before each create.

–add-drop-trigger

Add a DROP TRIGGER statement before each CREATE TRIGGER.

–add-locks

Add locks around INSERT statements, which results in faster inserts when the dump file is reloaded. Use –skip-add-locks to disable.

–allow-keywords

Allow creation of column names that are keywords. This works by prefixing each column name with the table name.

–apply-slave-statements

Adds STOP SLAVE prior to CHANGE MASTER and START SLAVE to the bottom of the dump.

–as-of=name

As of the given timestamp, dump the system versioned table(s). Note that table structures are always dumped regardless of the date/time specified; only the data is filtered by the timestamp. The `--tz-utc` setting is used to understand the timestamp argument; for important interaction details, see –tz-utc. This option is available from MariaDB 10.7.

If no data is available for the specified timestamp (for example, a date before any records were entered), only the table structure (CREATE, TABLE statement) will be dumped.

For example:

```
CREATE TABLE t1 (a INT) WITH SYSTEM VERSIONING;
INSERT t1 (a) VALUES (1),(2),(3);
DELETE FROM t1 WHERE a=1;
```

Dump result:

```
./bin/mysqldump -uroot -S./socket.sock --compact --as-of="1990-01-01 00:01" test t1
```

This dumps the table structure but not the data (since no records existed at that time). See MDEV-26943 for more information regarding the interaction with `--tz-utc`.

Note: When `--tz-utc` is enabled (which is the default), the timestamp value supplied to `--as-of` is interpreted in UTC. Remember that the effective filter time can differ if you are passing a local time. See –tz-utc and –skip-tz-utc.

–character-sets-dir=name

Directory for character set files.

-i, –comments

Write additional information in the dump file, such as program version, server version, and host. Disable with `--skip-comments`.

–compact

Give less verbose output (useful for debugging). Disables structure comments and header/footer constructs. Enables the `--skip-add-drop-table`, `--skip-add-locks`, `--skip-comments`, `--skip-disable-keys`, and `--skip-set-charset` options.

–compatible=name

Change the dump to be compatible with a given mode. By default, tables are dumped in a format optimized for MariaDB and MySQL. Legal modes are: ansi, `mysql323`, `mysql40`, `postgresql`, `oracle`, `mssql`, `db2`, `maxdb`, `no_key_options`, `no_table_options`, and `no_field_options`. You can use several modes, separated by commas. This option does not guarantee compatibility with other servers. It only enables those SQL mode values that are available for making dump output more compatible. For example, `--compatible=oracle` does not map data types to Oracle types or use Oracle comment syntax.

-c, –complete-insert

Use complete INSERT statements that include column names. From MariaDB 13.1, generated columns are omitted from the column list.

-C, –compress

Use compression in the server/client protocol. Both client and server must support compression for this to work.

–copy-s3-tables

By default, S3 tables are ignored. With this option set, the result file will contain a `CREATE` statement for a similar Aria table, followed by the table data and ending with an `ALTER TABLE`` `` *`table`* `` ``ENGINE=S3`.

-a, –create-options

Include all MariaDB and/or MySQL-specific create options in `CREATE TABLE` statements. Use `--skip-create-options` to disable.

-B, –databases

Dump several databases. Normally, `mariadb-dump` treats the first name argument on the command line as a database name and the following names as table names. With this option, it treats all name arguments as database names. CREATE DATABASE and USE statements are included in the output before each new database.

-#, –debug[=#]

If using a debug version of MariaDB, write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default value is `d:t:o,/tmp/mysqldump.trace`. If using a non-debug version, `mariadb-dump` will catch this and exit.

–debug-check

Check memory and open file usage at exit.

–debug-info

Print some debug info at exit.

–default-auth=*name*

Default authentication client-side plugin to use.

–default-character-set=*name*

Set the default character set to *name*. If no character set is specified, `mariadb-dump` uses utf8mb4.

–defaults-extra-file=*name*

Read the file *name* after the global files are read. Must be given as the first argument.

–defaults-file=*name*

Only read default options from the given file *name*. Must be given as the first argument.

–defaults-group-suffix=*str*

Also read groups with a suffix of *str*. For example, since `mariadb-dump` normally reads the `[client]` and `[mariadb-dump]` (or `[mysqldump]`) groups, `--defaults-group-suffix=` *`x`* would cause it to also read the groups `[mariadb-dump_` *`x`* `]` (or `[mysqldump_` *`x`* `]`) and `[client_` *`x`* `]`.

–delayed-insert

Insert rows with INSERT DELAYED instead of INSERT.

–delete-master-logs

On a primary replication server, delete the binary logs by sending a PURGE BINARY LOGS statement to the server after performing the dump operation. This option automatically enables `--master-data=2`.

–dir

Parallel dump of multiple databases. Works just like `--tab`, with regard to output (sql file for table definition and tab-separated for data, same options, for example, `--parallel`). It also allows the `--databases` and `--all-databases` options. When `--dir` is used, it creates the directory structure in the output directory pointed to by `--dir`. For every database to be dumped, there is a directory with the database name. All options that `--tab` supports are also supported by `--dir`, in particular `--parallel`. This option is available from MariaDB 11.5.

-K, –disable-keys

'`/*!40000 ALTER TABLE`` ``` *`tb_name`* ``DISABLE KEYS`` */;` *and* `'/ !40000 ALTER TABLE`` ``` *`tb_name`* ``` ``ENABLE KEYS */;` are written to the output. This makes loading the dump file faster because the indexes are created after all rows are inserted. This option is effective only for non-unique indexes of MyISAM tables. Disable with `--skip-disable-keys`.

–dump-date

If the `--comments` option and this option are given, `mariadb-dump` produces a comment at the end of the dump of the following form: `-- Dump completed on`` ``` *`date`*. However, the date causes dump files taken at different times to appear to be different, even if the data are otherwise identical. `--dump-date` and `--skip-dump-date`

control whether the date is added to the comment. The default is `--dump-date` (include the date in the comment). `--skip-dump-date` suppresses date printing.

-H, –dump-history

Dump tables with history. This option is available from MariaDB 10.11. Until this option was introduced, `mariadb-dump` could not read historical rows from versioned tables, and so historical data would not be backed up. Use also `--update-history` if upgrading to MariaDB 11.5 or newer from a version before 11.5.

–dump-slave[=value]

Used for producing a dump file from a replica server that can be used to set up another replica server with the same primary. Causes the binary log position and filename of the primary to be appended to the dumped data output. Setting the value to `1` (the default) prints it as a CHANGE MASTER command in the dumped data output; if set to `2`, that command is prefixed with a comment symbol. This option will turn on `--lock-all-tables`, unless `--single-transaction` is specified, too (in which case a global read lock is only taken a short time at the beginning of the dump. Make sure to read about `--single-transaction` below). In all cases, any action on logs happens at the exact moment of the dump. This option automatically turns off `--lock-tables`.

> **CURRENT**
>
> This option pauses any running SQL threads during the dump.
>
> **< 10.11**
>
> This option stops any running SQL threads before the dump, and restarts **all stopped IO and SQL** threads after completion.

-E, –events

Include Event Scheduler events for the dumped databases in the output.

-e, –extended-insert

Use multiple-row INSERT syntax that includes several value lists. This results in a smaller dump file and speeds up inserts when the file is reloaded. Defaults to `ON`; use `--skip-extended-insert` to disable.

–fields-terminated-by=*string*

Fields in the output file are terminated by the given *string*. Used with the `--tab` option and has the same meaning as the corresponding `FIELDS` clause for LOAD DATA INFILE.

–fields-enclosed-by=*character*

Fields in the output file are enclosed by the given *character*. Used with the `--tab` option and has the same meaning as the corresponding `FIELDS` clause for LOAD DATA INFILE.

–fields-optionally-enclosed-by=*character*

Fields in the output file are optionally enclosed by the given *character*. Used with the `--tab` option and has the same meaning as the corresponding `FIELDS` clause for LOAD DATA INFILE.

–fields-escaped-by=*character*

Fields in the output file are escaped by the given *character*. Used with the –tab option and has the same meaning as the corresponding `FIELDS` clause for LOAD DATA INFILE.

–first-slave

Removed in MariaDB 5.5. Use `--lock-all-tables` instead.

-F, –flush-logs

Flush the MariaDB server log files before starting the dump. This option requires the RELOAD privilege. If you use this option in combination with the `--databases=` or `--all-databases` option, the logs are flushed for each database dumped. The exception is when using `--lock-all-tables` or `--master-data`: In this case, the logs are flushed only once, corresponding to the moment all tables are locked. If you want your dump and the log flush to happen at the same exact moment, you should use `--flush-logs` together with either `--lock-all-tables` or `--master-data`.

–flush-privileges

Send a FLUSH PRIVILEGES statement to the server after dumping the mysql database. This option should be used any time the dump contains the mysql database and any other database that depends on the data in the mysql database for proper restoration.

-f, –force

Continue even if an SQL error occurs during a table dump. One use for this option is to cause mariadb-dump to continue executing even when it encounters a view that has become invalid because the definition refers to a table that has been dropped. Without `--force` in this example, mariadb-dump exits with an error message. With `--force`, mariadb-dump prints the error message, but it also writes an SQL comment containing the view definition to the dump output and continues executing.

–gtid

Used together with `--master-data` and `--dump-slave` to more conveniently set up a new GTID replica. It causes those options to output SQL statements that configure the replica to use the global transaction ID to connect to the primary instead of old-style filename/offset positions. The old-style positions are still included in comments when –gtid is used; likewise, the GTID position is included in comments even if `--gtid` is not used.

–header

When used together with `--tab`, enabling this option adds a header row containing column names at the top of the output `.txt` files.

-?, –help

Display a help message and exit.

–hex-blob

Dump binary strings in hexadecimal format (for example, ´abc´ becomes 0x616263). The affected data types are BINARY, VARBINARY, the BLOB types, and BIT.

-h name, –host=*host*

Connect to and dump data from the MariaDB or MySQL server on the given *host*. The default host is `localhost`.

–ignore-database=*database*

Do not dump the specified *database*. To specify more than one database to ignore, use the directive multiple times, once for each database. Only takes effect when used together with `--all-databases` or `-A`.

–ignore-table=*table*

Do not dump the specified *table*. To specify more than one table to ignore, use the directive multiple times, once for each table. Each table must be specified with both database and table names, for example, `--ignore-table=` *`database.table`*. This option can also be used to ignore views.

–ignore-table-data=*table*

Do not dump the specified *table* data (only the structure). To specify more than one table to ignore, use the directive multiple times, once for each table. Each table must be specified with both the database and table names. See also `--no-data`.

–include-master-host-port

Add the `MASTER_HOST` and `MASTER_PORT` options for the CHANGE MASTER TO statement when using the `--dump-slave` option for a replica dump.

–insert-ignore

Insert rows with `INSERT IGNORE` instead of `INSERT`.

–lines-terminated-by=*string*

Lines in the output file are terminated by the given *string*. This option is used with the `--tab` option and has the same meaning as the corresponding `LINES` clause for LOAD DATA INFILE.

-x, –lock-all-tables

Lock all tables across all databases. This is achieved by acquiring a global read lock for the duration of the whole dump by executing FLUSH TABLES WITH READ LOCK. This option automatically turns off `--single-transaction` and `--lock-tables`.

-l, –lock-tables

For each dumped database, lock all tables to be dumped before dumping them. The tables are locked with `READ LOCAL` to allow concurrent inserts in the case of MyISAM tables. For transactional tables such as InnoDB, `--single-transaction` is a much better option than `--lock-tables` because it does not need to lock the tables at all. Because `--lock-tables` locks tables for each database separately, this option does not guarantee that the tables in the dump file are logically consistent between databases. Tables in different databases may be dumped in completely different states. Use `--skip-lock-tables` to disable.

-L, –wildcards

> **Note:**
>
> This option is available from MariaDB 12.1.

Usage of wildcards in the table or database name. Without the –databases option, wildcards are only recognized in table names. With the “databases” option - in databases names.

–log-error=*file*

Log warnings and errors by appending them to the named *file*. The default is no logging.

–log-queries

When restoring the dump, if logging is turned on, the server logs queries to the general and slow query log. Defaults to `ON`; use `--skip-log-queries` to disable.

–master-data[=#]

Causes the binary log position and filename to be appended to the output, useful for dumping a primary replication server to produce a dump file that can be used to set up another server as a replica of the primary. These are the primary server coordinates from which the replica should start replicating after you load the dump file into the replica.

If the option is set to `1` (the default), print it as a CHANGE MASTER command; if set to `2`, that command is prefixed with a comment symbol. This `--master-data` option turns `--lock-all-tables` on, unless `--single-transaction` is specified, too. In all cases, any action on logs will happen at the exact moment of the dump. This option automatically turns `--lock-tables` off. In all cases, any action on logs happens at the exact moment of the dump. It is also possible to set up a replica by dumping an existing replica of the primary. To do this, use the following procedure on the existing replica:

Step 1

Stop the SQL thread of the replica and get its current status.

```
STOP SLAVE SQL_THREAD;
SHOW REPLICA STATUS;
```

Step 2

From the output of the `SHOW REPLICA STATUS` statement, the binary log coordinates of the primary server from which the new replica should start replicating are the values of the `Relay_Master_Log_File` and `Exec_Master_Log_Pos` fields. Denote those values as `file_name` and `file_pos`.

Step 3

Dump the replica server.

```
mariadb-dump --master-data=2 --all-databases > dumpfile
```

Step 4

Restart the replica.

```
START REPLICA;
```

Step 5

On the new replica, load the dump file.

```
mariadb < dumpfile
```

Step 6

On the new replica, set the replication coordinates to those of the primary server obtained earlier.

```
CHANGE MASTER TO
       MASTER_LOG_FILE = ´file_name´,
       MASTER_LOG_POS = file_pos;
```

The `CHANGE MASTER TO` statement might also need other parameters, such as `MASTER_HOST` to point the replica to the correct primary server host. Add any such parameters as necessary.

–max-allowed-packet=#

The maximum packet length to send to or receive from the server. The maximum is 1GB.

–max-statement-time=#

Sets the maximum time any statement can run before being timed out by the server. Default value is `0` (no limit).

–net-buffer-length=#

The initial buffer size for client/server TCP/IP and socket communication. This can be used to limit the size of rows in the dump. When creating multiple-row `INSERT` statements (as with the `--extended-insert` or `--opt` option), `mariadb-dump` creates rows up to `net_buffer_length` length.

–no-autocommit

Enclose the INSERT statements for each dumped table within SET autocommit = 0 and COMMIT statements. `ON` by default from MariaDB 11.8 to allow faster data loading by InnoDB, writing only one undo log for the whole operation.

-n, –no-create-db

This option suppresses the CREATE DATABASE … IF EXISTS statement that normally is output for each dumped database if `--all-databases` or `--databases` is given.

-t, –no-create-info

Do not write CREATE TABLE statements, which re-create each dumped table.

-d, –no-data

Do not write any table row information (that is, do not dump table contents). This is useful if you want to dump only the CREATE TABLE statement for the table (for example, to create an empty copy of the table by loading the dump file). See also `--ignore-table-data`.

–no-data-med

Do not dump rows for engines that manage external data (for instance, MRG_MyISAM, MRG_ISAM, CONNECT, OQGRAPH, Spider, VP, Federated). This option is enabled by default. If you want to dump data for these engines, you need to set `--no-data-med=0`.

–no-defaults

Don't read default options from any option file. Must be given as the first argument.

-N, –no-set-names

Suppress the `SET NAMES` statement. This has the same effect as `--skip-set-charset`.

–opt

This option is shorthand. It is the same as specifying `--add-drop-table`, `--add-locks`, `--create-options`, `--quick`, `--extended-insert`, `--lock-tables`, `--set-charset`, and `--disable-keys`. Enabled by default, disable with `--skip-opt`. It should give you a fast dump operation and produce a dump file that can be reloaded into a MariaDB server quickly. The `--opt` option is enabled by default. Use `--skip-opt` to disable it. See the discussion at the beginning of this section for information about selectively enabling or disabling a subset of the options affected by `--opt`.

–order-by-primary

Sorts each table's rows by primary key, or first unique key, if such a key exists. This is useful when dumping a MyISAM table to be loaded into an InnoDB table, but it will make the dump itself take considerably longer.

–order-by-size

Dump each table according to its size, smallest first. Useful when using `--single-transaction` on tables which get truncated/altered often. The assumption here is that smaller tables get truncated more often, and by dumping those first, this reduces the chance that a `--single-transaction` dump will fail with 'Table definition has changed, please retry transaction'. This option is available from MariaDB 10.9.1.

-j, –parallel=#

Number of dump table jobs executed in parallel (only for use with the `--tab` option). Testing indicates that performance can be increased (dump time decreased) up to 4 times on smaller-sized dumps, when the database fits into memory. There is a point at which the disk becomes the bottleneck, after which adding more parallel jobs does not bring better performance. From MariaDB 11.4.1.

-p[*password*], –password=*password*

The *password* to use when connecting to the server. If you use the short option form (`-p`), you cannot have a space between the option and the password. If you omit the password value following the `--password` or `-p` option on the command line, `mariadb-dump` prompts for one. Specifying a password on the command line should be considered insecure. You can use an option file to avoid giving the password on the command line.

-W, –pipe

On Windows, connect to the server via a named pipe. This option applies only if the server supports named-pipe connections.

–plugin-dir

Directory for client-side plugins.

-P *port*, –port=*port*

The TCP/IP *port number* to use for the connection.

–print-defaults

Print the program argument list and exit. Must be given as the first argument.

–protocol=name

The connection protocol to use for connecting to the server (`TCP`, `SOCKET`, `PIPE`, `MEMORY`). It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want.

-q, –quick

This option is useful for dumping large tables. It forces `mariadb-dump` to retrieve rows for a table from the server, a row at a time, and to then dump the results directly to stdout rather than retrieving the entire row set and buffering it in memory before writing it out. Defaults to `ON`, use `--skip-quick` to disable.

-Q, –quote-names

Quote identifiers (such as database, table, and column names) within backtick (`` ` ``) characters. If the `ANSI_QUOTES` SQL mode is enabled, identifiers are quoted with (`"`) characters. This option is enabled by default. It can be disabled with `--skip-quote-names`, but this option should be given after any option such as `--compatible` that may enable `--quote-names`.

–replace

Use REPLACE INTO statements instead of INSERT INTO statements.

-r, –result-file=*file*

Direct output to a given *file*. This option should be used on Windows to prevent newline (`\n`) characters from being converted to `\r\n` carriage return/newline sequences. The result file is created and its previous contents overwritten, even if an error occurs while generating the dump.

-R, –routines

Include stored routines (procedures and functions) for the dumped databases in the output. Use of this option requires the SELECT privilege for the mysql.proc table. The output generated using –routines contains CREATE PROCEDURE and CREATE FUNCTION statements to re-create the routines. However, these statements do not include attributes such as the routine creation and modification timestamps. This means that when the routines are reloaded, they are created with the timestamps equal to the reload time. If you require routines to be re-created with their original timestamp attributes, do not use `--routines`. Instead, dump and reload the contents of the mysql.proc table directly, using a MariaDB account, which has appropriate privileges for the mysql database.

–set-charset

Add `'SET NAMES default_character_set'` to the output in order to set the character set. Enabled by default; suppress with `--skip-set-charset`.

-O, –set-variable=*variable*

Change the value of a *variable*. This option is deprecated; you can set variables directly with `-- variable-name = value`.

–shared-memory-base-name

Shared-memory name to use for Windows connections using shared memory to a local server (started with the `--shared-memory` option). Case-sensitive. Defaults to `MYSQL`.

–single-transaction

This option sends a START TRANSACTION SQL statement to the server before dumping data. It is useful only with transactional tables such as InnoDB, because then it dumps the consistent state of the database at the time when `BEGIN` was issued, without blocking any applications. When using this option, you should keep in mind that only InnoDB tables are dumped in a consistent state. The single-transaction feature depends not only on the engine being transactional and capable of `REPEATABLE-READ`, but also on `START TRANSACTION WITH CONSISTENT SNAPSHOT`. The dump is not guaranteed to be consistent for other storage engines. For example, any MyISAM, or MEMORY tables dumped while using this option may still change state. While a `--single-transaction` dump is in process, to ensure a valid dump file (correct table contents and binary log coordinates), no other connection should use the following statements: ALTER TABLE, CREATE TABLE, DROP TABLE, RENAME TABLE, or TRUNCATE TABLE. A consistent read is not isolated from those statements, so use of them on a table to be dumped can cause the `SELECT` (performed by mariadb-dump to retrieve the table contents) to obtain incorrect contents or fail. The `--single-transaction` option and the `--lock-tables` option are mutually exclusive, because LOCK TABLES causes any pending transactions to be committed implicitly. So, this option automatically turns off `--lock-tables`. To dump large tables, you should combine the `--single-transaction` option with `--quick`.

–skip-add-locks

Disable the `--add-locks` option.

–skip-comments

Disable the `--comments` option.

–skip-disable-keys

Disable the `--disable-keys` option.

–skip-extended-insert

Disable the `--extended-insert` option.

–skip-opt

Disable the `--opt` option (disables `--add-drop-table`, `--add-locks`, `--create-options`, `--quick`, `--extended-insert`, `--lock-tables`, `--set-charset`, and `--disable-keys`).

–skip-quick

Disable the `--quick` option.

–skip-quote-name

Disable the `--quote-names` option.

–skip-set-charset

Disable the `--set-charset` option.

–skip-triggers

Disable the `--triggers` option.

–skip-tz-utc

Disables the `--tz-utc` option. When `--skip-tz-utc` is specified, the `--tz-utc` behavior is disabled. `mariadb-dump` will not set its connection time zone to UTC before the dump, and will not add `SET TIME_ZONE='+00:00'` to the top of the dump file. TIMESTAMP values will therefore be dumped in the local time zone of the server. When the dump is reloaded on a server in a different time zone or during daylight saving time transitions, remember that this may result in different timestamp values. See –tz-utc.

-S name, –socket={*socket|named-pipe*}

For connections to localhost, the Unix *socket file* to use, or, on Windows, the name of the *named pipe* to use.

–ssl

Enables TLS. TLS is also enabled even without setting this option when certain other TLS options are set. The `--ssl` option does not enable verifying the server certificate by default. In order to verify the server certificate, the user must specify the `--ssl-verify-server-cert` option.

–ssl-ca=*pem-file*

Defines a path to a *PEM file* that should contain one or more X509 certificates for trusted Certificate Authorities (CAs) to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option implies the `--ssl` option.

–ssl-capath=*pem-directory*

Defines a *path to a directory that contains one or more PEM files* that should each contain one X509 certificate for a trusted Certificate Authority (CA) to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the openssl rehash command. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option is only supported if the client was built with OpenSSL or yaSSL. If the client was built with GnuTLS or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms. This option implies the `--ssl` option.

–ssl-cert=*certificate-file*

Defines a path to the *X509 certificate file* to use for TLS. This option requires that you use the absolute path, not a relative path. This option implies the `--ssl` option.

–ssl-cipher=*cipher-list*

List of permitted ciphers or cipher suites to use for TLS. This option implies the `--ssl` option.

–ssl-crl=*pem-file*

Defines a *path to a PEM file* that should contain one or more revoked X509 certificates to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL or Schannel. If the client was built with yaSSL or GnuTLS, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.

–ssl-crlpath=*pem-directory*

Defines a *path to a directory that contains one or more PEM files* that should each contain one revoked X509 certificate to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the openssl rehash command. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL. If the client was built with yaSSL, GnuTLS, or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.

–ssl-fp=name

Server certificate fingerprint (implies `--ssl`).

–ssl-fplist=name

File with accepted server certificate fingerprints, one per line (implies `--ssl`).

–ssl-key=*private-key*

Defines a *path to a private key file* to use for TLS. This option requires that you use the absolute path, not a relative path. This option implies the `--ssl` option.

–ssl-verify-server-cert

Enables server certificate verification. This option is disabled by default.

–system=*option*[,*option*]]

Dump the database's system tables in a logical form. With this option, the mysql database tables are dumped as CREATE USER, CREATE SERVER, and other forms of logical portable SQL statements. The option values here are from the set of `all`, `users`, `plugins`, `udfs`, `servers`, `stats`, and `timezones`.

-T, –tab=*name*

Produce tab-separated text-format data files. With this option, for each dumped table, `mariadb-dump` creates a `tbl_name.sql` file containing the `CREATE TABLE` statement that creates the table, and a `tbl_name.txt` file containing the table's data. The option value is the directory in which to write the files. Note: This option can only be used when `mariadb-dump` is run on the same machine as the `mariadbd` server. You must have the `FILE` privilege, and the server must have permission to write files in the directory that you specify. By default, the `.txt` data files are formatted using tab characters between column values and a newline at the end of each line. The format can be specified explicitly using the `--fields-` *`xxx`* and `--lines-terminated-by` options. Column values are converted to the character set specified by the `--default-character-set` option.

–tables

This option overrides the `--databases` (`-B`) option. `mariadb-dump` regards all name arguments following the option as table names.

–tls-version=*protocol*

This option accepts a *comma-separated list of TLS protocol versions*. A TLS protocol version will only be enabled if it is present in this list. All other TLS protocol versions will not be permitted. See Secure Connections Overview: TLS Protocol Versions for more information.

–triggers

Include triggers for each dumped table in the output. This option is enabled by default; disable it with `--skip-triggers`.

–tz-utc

This option enables TIMESTAMP columns to be dumped and reloaded between servers in different time zones. `mariadb-dump` sets its connection time zone to UTC before starting the dump and adds `SET TIME_ZONE='+00:00'` to the top of the dump file. Without this option, `TIMESTAMP` columns are dumped and reloaded in the time zones local to the source and destination servers, which can cause the values to change if the servers are in different time zones. This option also protects against changes due to daylight saving time. The time zone setting affects how timestamp arguments (like those in `--as-of`) are interpreted.

`--tz-utc` is enabled by default. To disable it, use `--skip-tz-utc`.

Note the interaction of this option with `--as-of` when dumping versioned data.

–update-history

This option updates the `row_end` history timestamp to support dates up to the year 2106. When enabled, it also activates `tz-utc`. The option should be used when upgrading to **MariaDB 11.5 or later**, ensuring compatibility with extended date ranges and proper time zone handling.

-u *username*, –user=*username*

The MariaDB *user name* to use when connecting to the server.

-v, –verbose

Verbose mode. Print more information about what the program is doing during various stages.

-V, –version

Output version information and exit.

-w *condition*, –where=*condition*

Dump only rows selected by the given `WHERE` *condition*. Quotes around the condition are mandatory if it contains spaces or other characters that are special to your command interpreter. Example:\ `--where="user = ´jimf´" -w"userid > 1" -w"userid < 1"` .

-X, –xml

Dump a database as well-formed XML.

Group Options

Some `mariadb-dump` options are shorthand for groups of other options:

- Use of `--opt` is the same as specifying `--add-drop-table` , `--add-locks` , `--create-options` , `--disable-keys` , `--extended-insert` , `--lock-tables` , `--quick` , and `--set-charset` . All of the options that `--opt` stands for are also on by default because `--opt` is on by default.
- Use of `--compact` is the same as specifying `--skip-add-drop-table` , `--skip-add-locks` , `--skip-comments` , `--skip-disable-keys` , and `--skip-set-charset` options.

To reverse the effect of a group option, use its `--skip-xxx` form (`--skip-opt` or `--skip-compact`). It is also possible to select only part of the effect of a group option by following it with options that enable or disable specific features. Here are some examples:

- To select the effect of `--opt` except for some features, use the `--skip` option for each feature. To disable extended inserts and memory buffering, use `--opt--skip-extended-insert` `--skip-quick` . (Actually, `--skip-extended-insert--skip-quick` is sufficient because `--opt` is on by default.)
- To reverse `--opt` for all features except index disabling and table locking, use `--skip-opt--disable-keys` `--lock-tables` .

When you selectively enable or disable the effect of a group option, the order is important because options are processed first to last. For example, `--disable-keys` `--lock-tables--skip-opt` would not have the intended effect; it is the same as `--skip-opt` by itself.

Special Characters in Option Values

Some options, like `--lines-terminated-by` , accept a string. The string can be quoted, if necessary. For example, on Unix systems, this is the option to enclose fields within double quotes:

```
--fields-enclosed-by='"'
```

An alternative is to specify the hexadecimal value of a character. For example, the following syntax works on any platform:

```
--fields-enclosed-by=0x22
```

Option Files

In addition to reading options from the command line, `mariadb-dump` can also read options from option files. If an unknown option is provided to `mariadb-dump` in an option file, then it is ignored.

The following options relate to how MariaDB command-line tools handle option files. They must be given as the first argument on the command line:

Option	Description
–print-defaults	Print the program argument list and exit.
–no-defaults	Don’t read default options from any option file.

Option	Description
–defaults-file=#	Only read default options from the given file #.
–defaults-extra-file=#	Read this file after the global files are read.
–defaults-group-suffix=#	In addition to the default option groups, also read option groups with this suffix.

`mariadb-dump` is linked with MariaDB Connector/C. However, MariaDB Connector/C does not handle the parsing of option files for this client. That is performed by the server's option file parsing code. See MDEV-19035 for more information.

Option Groups

`mariadb-dump` reads options from the following option groups from the option files:

Group	Description
[mysqldump]	Options read by mariadb-dump, which includes both MariaDB Server and MySQL Server.
[mariadb-dump]	Options read by `mariadb-dump`.
[client]	Options read by all MariaDB and MySQL client programs, which include both MariaDB and MySQL clients. For example, mysqldump.
[client-server]	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which are common between the server and the clients.
[client-mariadb]	Options read by all MariaDB client programs.

NULL, ´NULL´, and Empty Values in XML

For a column named `column_name`, the `NULL` value, an empty string, and the string value `´NULL´` are distinguished from one another in the output generated by this option as follows.

Value	XML Representation
`NULL` (unknown value)	`<field name="column_name" xsi:nil="true" />`
`''` (empty string)	`<field name="column_name"></field>`
`'NULL'` (string value)	`<field name="column_name">NULL</field>`

The output from the mariadb client when run using the `--xml` option also follows the preceding rules.

XML output from mariadb-dump includes the XML namespace, as shown here:

```
shell> mariadb-dump --xml -u root world City
<?xml version="1.0"?>
<mariadb-dump xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<database name="world">
<table_structure name="City">
<field Field="ID" Type="int(11)" Null="NO" Key="PRI" Extra="auto_increment" />
<field Field="Name" Type="char(35)" Null="NO" Key="" Default="" Extra="" />
<field Field="CountryCode" Type="char(3)" Null="NO" Key="" Default="" Extra="" />
<field Field="District" Type="char(20)" Null="NO" Key="" Default="" Extra="" />
<field Field="Population" Type="int(11)" Null="NO" Key="" Default="0" Extra="" />
<key Table="City" Non_unique="0" Key_name="PRIMARY" Seq_in_index="1" Column_name="ID"
Collation="A" Cardinality="4079" Null="" Index_type="BTREE" Comment="" />
<options Name="City" Engine="MyISAM" Version="10" Row_format="Fixed" Rows="4079"

Index_length="43008" Data_free="0" Auto_increment="4080"
Create_time="2007-03-31 01:47:01" Update_time="2007-03-31 01:47:02"
Collation="latin1_swedish_ci" Create_options="" Comment="" />
</table_structure>
<table_data name="City">
<row>
<field name="ID">1</field>
<field name="Name">Kabul</field>
<field name="CountryCode">AFG</field>
<field name="District">Kabol</field>
<field name="Population">1780000</field>
</row>
...
<row>
<field name="ID">4079</field>
<field name="Name">Rafah</field>
<field name="CountryCode">PSE</field>
<field name="District">Rafah</field>
<field name="Population">92020</field>
</row>
</table_data>
</database>
</mariadb-dump>
```

Restoring Dumps

To restore a backup created with `mariadb-dump`, use the [mariadb client](../mariadb-client/mariadb-command line-client.md) to import the dump:

```
mariadb db_name < backup-file.sql
```

Variables

You can also set the following variables (`--variable-name=value`) and boolean options `{FALSE|TRUE}` by using:

Name	Default Values
all	TRUE
all-databases	FALSE
all-tablespaces	FALSE
no-tablespaces	FALSE
add-drop-database	FALSE
add-drop-table	TRUE
add-drop-trigger	FALSE
add-locks	TRUE

where	(No default value)
plugin-dir	(determined by installation path, e.g. `.../lib/plugin`)
default-auth	(No default value)

Examples

A common use of `mariadb-dump` is making a backup of an entire database:

```
shell> mariadb-dump db_name > backup-file.sql
```

You can load the dump file back into the server like this:

```
shell> mariadb db_name < backup-file.sql
```

Or like this:

```
shell> mariadb -e "source /path-to-backup/backup-file.sql" db_name
```

`mariadb-dump` is also very useful for populating databases by copying data from one MariaDB server to another:

```
shell> mariadb-dump --opt db_name | mariadb --host=remote_host -C db_name
```

It is possible to dump several databases with one command:

```
shell> mariadb-dump --databases db_name1 [db_name2 ...] > my_databases.sql
```

To dump all databases, use the `--all-databases` option:

```
shell> mariadb-dump --all-databases > all_databases.sql
```

For InnoDB tables, `mariadb-dump` provides a way of making an online backup:

```
shell> mariadb-dump --all-databases --single-transaction all_databases.sql
```

This backup acquires a global read lock on all tables (using `FLUSH TABLES WITH READ LOCK`) at the beginning of the dump. As soon as this lock has been acquired, the binary log coordinates are read, and the lock is released. If long updating statements are running when the `FLUSH` statement is issued, the MariaDB server may get stalled until those statements finish. After that, the dump becomes lock-free and does not disturb reads and writes on the tables. If the update statements that the MariaDB server receives are short (in terms of execution time), the initial lock period should not be noticeable, even with many updates.

For point-in-time recovery (also known as “roll-forward,” when you need to restore an old backup and replay the changes that happened since that backup), it is often useful to rotate the binary log or at least know the binary log coordinates to which the dump corresponds:

```
shell> mariadb-dump --all-databases --master-data=2 > all_databases.sql
```

Or:

```
shell> mariadb-dump --all-databases --flush-logs --master-data=2 > all_databases.sql
```

The `--master-data` and `--single-transaction` options can be used simultaneously, which provides a convenient way to make an online backup suitable for use prior to point-in-time recovery if tables are stored that use the InnoDB storage engine.

mariadb-hotcopy

`mariadb-hotcopy` is a Perl script that was originally written and contributed by Tim Bunce. It uses FLUSH TABLES, LOCK TABLES, and cp or scp to make a database backup.

> **Note:**
>
> Previously, the client was called `mysqlhotcopy`. It can still be accessed under this name, via a symlink in Linux, or an alternate binary in Windows.

It is a fast way to make a backup of the database or single tables, but it can be run only on the same machine where the database directories are located. `mariadb-hotcopy` works only for backing up MyISAM and ARCHIVE tables. It runs on Unix and NetWare.

To use `mariadb-hotcopy`, you must have read access to the files for the tables that you are backing up, the `SELECT` privilege for those tables, the `RELOAD` privilege (to be able to execute `FLUSH TABLES`), and the `LOCK TABLES` privilege (to be able to lock the tables).

```
shell> mariadb-hotcopy db_name [/path/to/new_directory]
shell> mariadb-hotcopy db_name_1 ... db_name_n /path/to/new_directory
```

Back up tables in the given database that match a regular expression:

```
shell> mariadb-hotcopy db_name./regex/
```

The regular expression for the table name can be negated by prefixing it with a tilde (`~`):

```
shell> mariadb-hotcopy db_name./~regex/
```

`mariadb-hotcopy` supports the following options, which can be specified on the command line or in the [`mariadb-hotcopy`] and [`client`] option file groups.

`--help`, `-?`

Display a help message and exit.

`--addtodest`

Do not rename target directory (if it exists); merely add files to it.

`--allowold`

Do not abort if a target exists; rename it by adding an _old suffix.

`--checkpoint` ***=db_name.tbl_name***

Insert checkpoint entries into the specified database *db_name* and table *tbl_name*.

`--chroot` ***=directory***

Base *directory* of the chroot jail in which mariadbd operates. The path value should match that of the `--chroot` option given to `mariadbd`.

`--debug`

Enable debug output.

`--dryrun`, **`-n`**

Report actions without performing them.

`--flushlog`

Flush logs after all tables are locked.

`--host` ***=host_name***, **`-h`** ***host_name***

The *host name* of the local host to use for making a TCP/IP connection to the local server. By default, the connection is made to localhost using a Unix socket file.

`--keepold`

Do not delete previous (renamed) target when done.

`--method` ***=method***

The *method* for copying files (`cp` or `scp`). The default is `cp`.

`--noindices`

Do not include full index files for MyISAM tables in the backup. This makes the backup smaller and faster. The indexes for reloaded tables can be reconstructed later with myisamchk -rq.

`--old-server`

Connect to old MySQL server (before MySQL 5.5) which doesn't have FLUSH TABLES WITH READ LOCK fully implemented.

`--password` ***=password***, **`-p`** ***password***

The *password* to use when connecting to the server. The password value is mandatory for this option, unlike for other MariaDB programs. Specifying a password on the command line should be considered insecure. You can use an option file to avoid giving the password on the command line.

`--port` ***=port-number***, **`-P`** ***port-number***

The TCP/IP *port number* to use when connecting to the local server.

`--quiet`, `-q`

Be silent except for errors.

`--record\_log\_pos`=*db_name*._tbl_name_

Record master and slave status in the specified database *db_name* and table *tbl_name*.

`--regexp`=*expression*

Copy all databases with names that match the given regular *expression*.

`--resetmaster`

Reset the binary log after locking all the tables.

`--resetslave`

Reset the `master.info` file after locking all the tables.

`--socket`=*socket-file*, `-S` *socket-file*

The Unix *socket file* to use for connections to localhost.

`--suffix`=*string*

The *suffix string* to use for names of copied databases.

`--tmpdir`=*directory*

The temporary *directory*. The default is `/tmp`.

`--user`=*username*, `-u` *username*

The MariaDB *username* to use when connecting to the server.

Use perldoc for additional `mariadb-hotcopy` documentation, including information about the structure of the tables needed for the `--checkpoint` and ``–record`_log_pos` options:

```
shell> perldoc mariadb-hotcopy
```

mariadb-import

`mariadb-import` loads tables from text files in various formats.

> **Note:**
>
> Previously, the client was called `mysqlimport`. It can still be accessed under this name, via a symlink in Linux, or an alternate binary in Windows.

`mariadb-import` loads tables from text files in various formats. The base name of the text file must be the name of the table that should be used. If one uses sockets to connect to the MariaDB server, the server will open and read

the text file directly. In other cases the client will open the text file. The SQL statement LOAD DATA INFILE is used to import the rows.

Usage

The command to use `mariadb-import` and the general syntax is:

```
mariadb-import [OPTIONS] database textfile1 [textfile2 ...]
```

Options

`mariadb-import` supports the following options:

`--character-sets-dir`=*directory*

Directory for character set files.

`-c` *cols*, `--columns`=*cols*

Use only these columns to import the data to. Give the column names in a comma separated list. This is same as giving columns to LOAD DATA INFILE.

`-C`, `--compress`

Use compression in server/client protocol.

`--database`=*database*

Restore the specified database, ignoring others.To specify more than one database to include, use the directive multiple times, once for each database. Only takes effect when used together with the `--dir` option. This option is available from MariaDB 11.6.

`--debug` [=options]

Output debug log. Often this is `d:t:o,filename`. The default is `d:t:o`.

`--debug-check`

Check memory and open file usage at exit.

`--debug-info`

Print some debug info at exit.

`--default-auth`=*plugin*

Default authentication client-side *plugin* to use.

`--default-character-set`=*character-set*

Set the default *character set*.

`--defaults-extra-file`=*file*

Read this *file* after the global files are read. Must be given as the first option.

`--defaults-file`=*file*

Only read default options from the given *file* name Must be given as the first option.

`--defaults-group-suffix` ***=group-suffix***

In addition to the given groups, also read groups with this *suffix*.

`-d`, **`--delete`**

First delete all rows from table.

`--dir` ***=directory***

Restore all tables from backup directory created using mariadb-dump –dir. This option is available from MariaDB 11.6.

`--fields-terminated-by` ***=string***

Fields in the input file are terminated by the given *string*.

`--fields-enclosed-by` ***=character***

Fields in the import file are enclosed by the given *character*.

`--fields-optionally-enclosed-by` ***=character***

Fields in the input file are optionally enclosed by the given *character*.

`--fields-escaped-by` ***=character***

Fields in the input file are escaped by the given *character*.

`-f`, **`--force`**

Continue even if we get an SQL error.

`-?`, **`--help`**

Display this help and exits.

`-h` ***host***, **`--host`** ***=host***

Connect to host.

`-i`, **`--ignore`**

If duplicate unique key was found, keep old row.

`-k`, **`--ignore-foreign-keys`**

Disable foreign key checks while importing the data.

`--ignore-database` ***=database***

Do not restore the specified database. To specify more than one database to ignore, use the directive multiple times, once for each database. Only takes effect when used together with the `--dir` option. This option is available from MariaDB 11.6.

`--ignore-lines` ***=n***

Ignore first n lines of data infile.

`--ignore-table` ***=table***

Do not restore the specified table. To specify more than one table to ignore, use the directive multiple times, once for each table. Each table must be specified with both database and table names, for instance, `--ignore-table`=*database*._table_. Only takes effect when used together with the `--dir` option. This option is available from MariaDB 11.6.

`--innodb-optimize-keys`

Create secondary indexes after data load, which speeds up loading (InnoDB only). Defaults to on; use `--skip-innodb-optimize-keys` to disable. This option is available from MariaDB 11.8.

`--lines-terminated-by` ***=string***

Lines in the input file are terminated by the given *string*.

`-L`, **`--local`**

Read all files through the client.

`-l`, **`--lock-tables`**

Lock all tables for write (this disables threads).

`--low-priority`

Use `LOW_PRIORITY` when updating the table.

`--no-defaults`

Don't read default options from any option file. Must be given as the first option.

`-j`, **`--parallel`** ***=number***

Number of LOAD DATA jobs executed in parallel. This option is available from MariaDB 11.4.1. `--use-threads` is a synonym.

`-p` ***password***, **`--password`** ***password***

Password to use when connecting to server. If password is not given, it's asked from the terminal. Specifying a password on the command line should be considered insecure. You can use an option file to avoid giving the password on the command line.

`--pipe`, **`-W`**

n Windows, connect to the server via a named pipe. This option applies only if the server supports named-pipe connections.

`--plugin-dir`

Directory for client-side plugins.

`-P` ***port-number***, **`--port`** ***=port-number***

Port number to use for connection or `0` for default to, in order of preference, `my.cnf`, the `MYSQL_TCP_PORT` environment variable, `/etc/services`. Default is `3306`.

`--print-defaults`

Print the program argument list and exit. Must be given as the first option.

`--protocol`=*protocol*

The *protocol* to use for connection (`tcp`, `socket`, `pipe`, `memory`).

`-r`, **`--replace`**

If duplicate unique key was found, replace old row.

`--shared-memory-base-name`

Shared-memory name to use for Windows connections using shared memory to a local server (started with the `--shared-memory` option). Case sensitive.

`-s`, **`--silent`**

Silent mode. Produce output only when errors occur.

`-S`, **`--socket`**={*socket*|*named-pipe*}

For connections to localhost, the Unix *socket* file to use, or, on Windows, the name of the *named pipe* to use.

`--ssl`

Enables TLS. TLS is also enabled even without setting this option when certain other TLS options are set. The `--ssl` option does not enable verifying the server certificate by default. In order to verify the server certificate, the user must specify the `--ssl-verify-server-cert` option.

`--ssl-ca`=*pem-file*

Define a path to a *PEM file* that should contain one or more X509 certificates for trusted Certificate Authorities (CAs) to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option implies the `--ssl` option.

`--ssl-capath`=*pem-directory*

Define a *path to a directory that contains one or more PEM files* that should each contain one X509 certificate for a trusted Certificate Authority (CA) to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the openssl rehash command. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option is only supported if the client was built with OpenSSL or yaSSL. If the client was built with GnuTLS or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms. This option implies the `--ssl` option. |

`--ssl-cert`=*file*

Define a path to the X509 *certificate file* to use for TLS. This option requires that you use the absolute path, not a relative path. This option implies the `--ssl` option.

`--ssl-cipher`=*cipher-list*

List of permitted ciphers or cipher suites to use for TLS. This option implies the `--ssl` option.

`--ssl-crl`=*pem-file*

Defines a path to a *PEM file* that should contain one or more revoked X509 certificates to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL or

Schannel. If the client was built with yaSSL or GnuTLS, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.

`--ssl-crlpath` *=pem-directory*

Define a *path to a directory that contains one or more PEM files* that should each contain one revoked X509 certificate to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the openssl rehash command. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL. If the client was built with yaSSL, GnuTLS, or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.

`--ssl-key` *=key-file*

Define a path to a private *key file* to use for TLS. This option requires that you use the absolute path, not a relative path. This option implies the `--ssl` option.

`--ssl-verify-server-cert`

Enable server certificate verification. This option is disabled by default.

`--table` *=table*

Restore the specified *table* ignoring others. Use `--table`=dbname.tablename with this option. To specify more than one table to include, use the directive multiple times, once for each table. Only takes effect when used together with the `--dir` option. This option is available from MariaDB 11.6.

`--tls-version` *=tls-list*

This option accepts a *comma-separated list of TLS protocol versions*. A TLS protocol version will only be enabled if it is present in this list. All other TLS protocol versions will not be permitted. See Secure Connections Overview: TLS Protocol Versions for more information.

`--use-threads` *=number*

Load files in parallel. The argument is the *number of threads* to use for loading data. From MariaDB 11.4.1, a synonym for -j, `--parallel`=num.

`-u` *username*, `--user` *=username*

User for login if not current user.

`-v`, `--verbose`

Print info about the various stages.

`-V`, `--version`

Output version information and exit.

Option Files

In addition to reading options from the command line, `mariadb-import` can also read options from option files. If an unknown option is provided to `mariadb-import` in an option file, then it is ignored.

The following options relate to how MariaDB command line tools handles option files. They must be given as the first argument on the command line:

Option	Description
`--print-defaults`	Print the program argument list and exit.
`--no-defaults`	Don't read default options from any option file.
`--defaults-file` =#	Only read default options from the given file #.
`--defaults-extra-file` =#	Read this file after the global files are read.

`mariadb-import` is linked with MariaDB Connector/C. Therefore, it may be helpful to see Configuring MariaDB Connector/C with Option Files for more information on how MariaDB Connector/C handles option files.

Option Groups

`mariadb-import` reads options from the following option groups from option files:

Group	Description
[mysqlimport]	Options read by mysqlimport, which includes both MariaDB Server and MySQL Server.
[mariadb-import]	Options read by mysqlimport.
[client]	Options read by all MariaDB and MySQL client programs, which includes both MariaDB and MySQL clients. For example, mysqldump.
[client-server]	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients.
[client-mariadb]	Options read by all MariaDB client programs.

Default Values

Variables	Value (after reading options)
character-sets-dir	(No default value)
default-character-set	latin1
columns	(No default value)
compress	FALSE
debug-check	FALSE
debug-info	FALSE
delete	FALSE
fields-terminated-by	(No default value)
fields-enclosed-by	(No default value)
fields-optionally-enclosed-by	(No default value)
fields-escaped-by	(No default value)
force	FALSE
host	(No default value)
ignore	FALSE
ignore-lines	0
lines-terminated-by	(No default value)
local	FALSE
lock-tables	FALSE

Variables	Value (after reading options)
low-priority	FALSE
port	3306
replace	FALSE
silent	FALSE
socket	/var/run/mysqld/mysqld.sock
ssl	FALSE
ssl-ca	(No default value)
ssl-capath	(No default value)
ssl-cert	(No default value)
ssl-cipher	(No default value)
ssl-key	(No default value)
ssl-verify-server-cert	FALSE
use-threads	0
user	(No default value)
verbose	FALSE

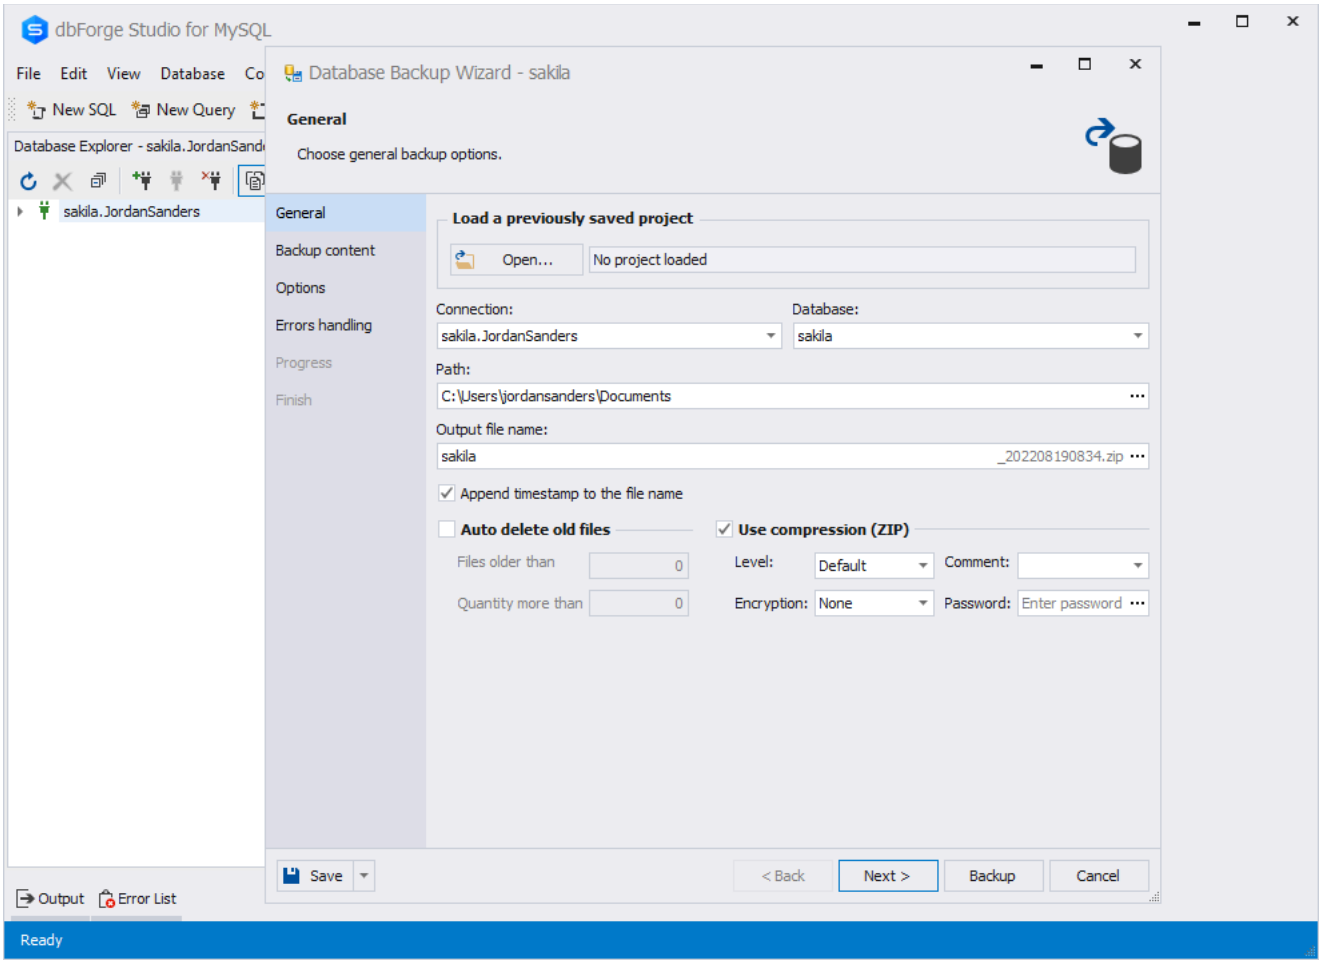
dbForge Studio

> **Note:**
>
> dbForge Studio is proprietary third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Content contributed by Devart; refer to its own documentation and license terms.

Without a doubt, you want your backup/restore and export/import operations to be fast, easy, and automated wherever possible. You can have it all that way with dbForge Studio for MySQL. As the name implies, it is an IDE for MySQL development, management, and administration, yet it works just as perfectly as a MariaDB GUI client. Now, let's see how it tackles routine database backups.

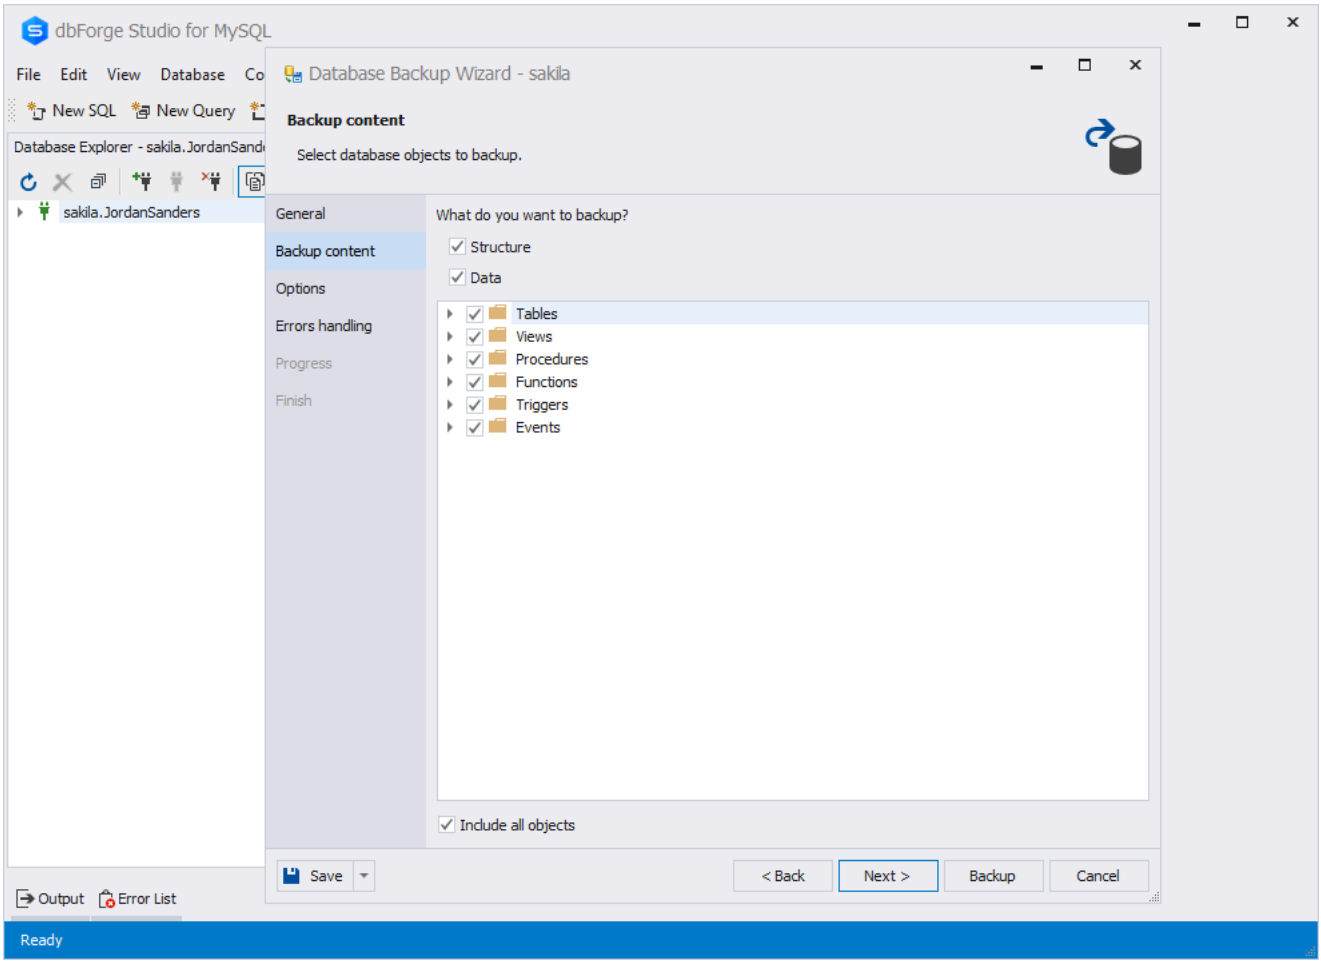
Create a MariaDB backup

1. On the **Database** menu, go to **Backup and Restore**, and click **Backup Database** to open **Database Backup Wizard**.
2. On the **General** page, specify the required connection and database, the path for the backup file to be saved to, and the output file name in the respective fields. Optionally, you can append a timestamp to the file name, enable the auto-deletion of old files, and compress your backup into an archive. After you set it all up, click **Next**.



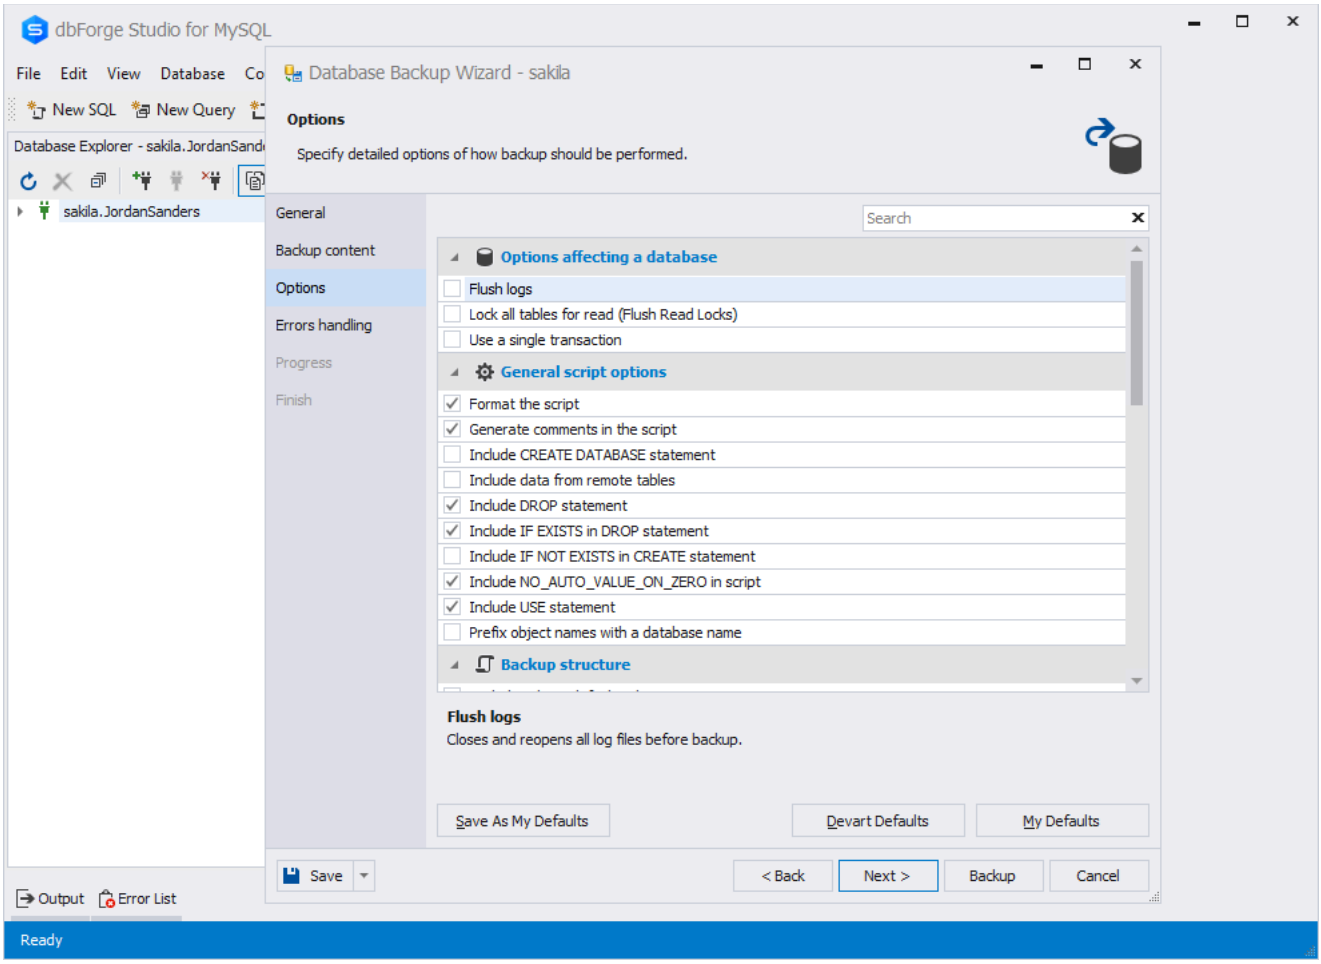
b1

3. On the **Backup content** page, select the content for your backup and click **Next**.



b2

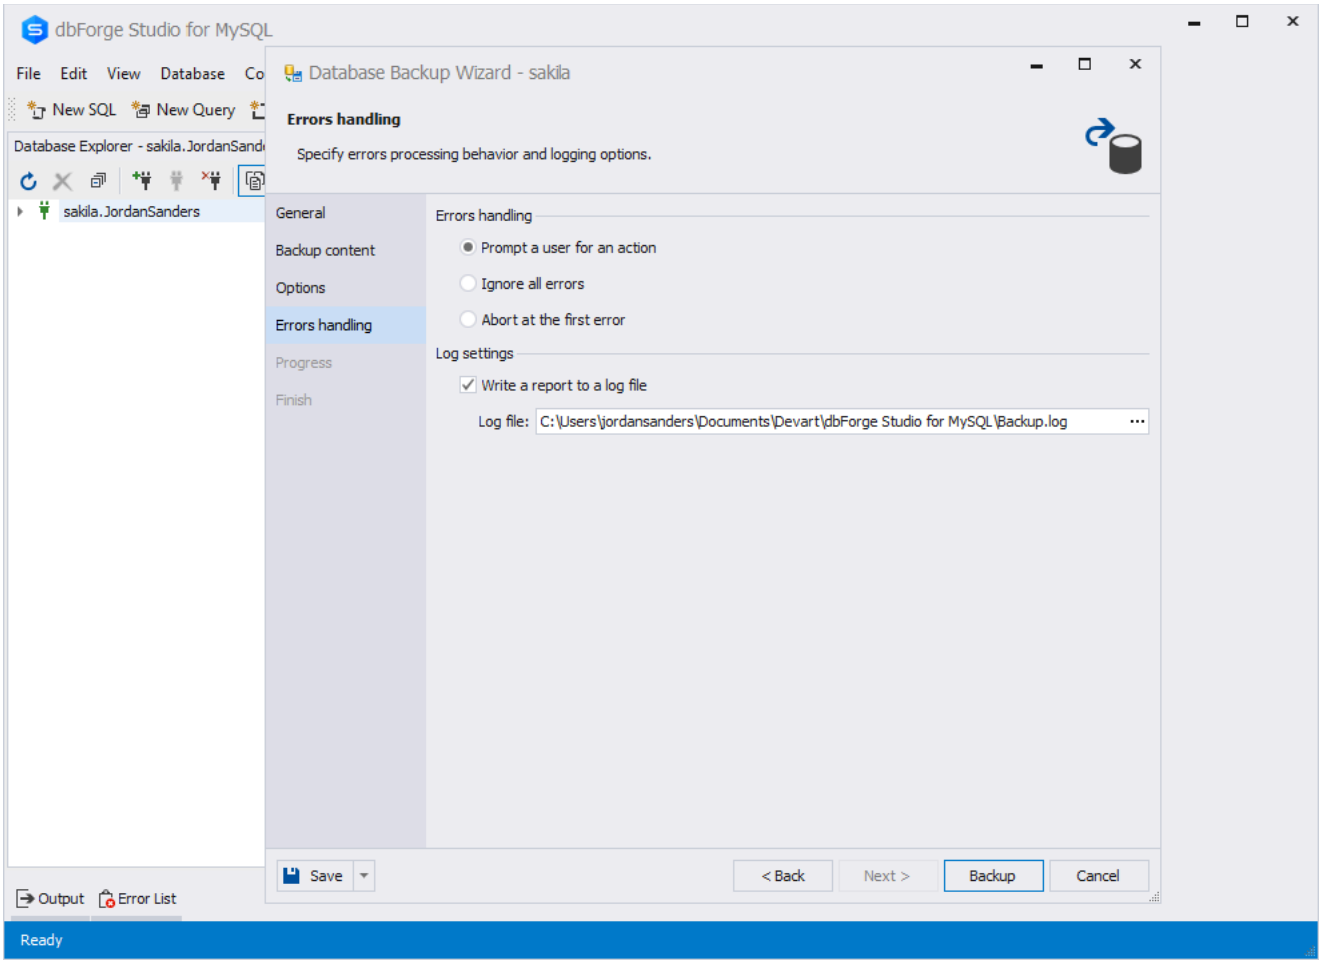
4. On the **Options** page, configure your detailed backup options—there are quite a few of those to match your requirements most precisely. Then click **Next**.



b3

5. On the **Errors handling** page, configure the **Errors handling** and **Log settings** options. Afterwards, click **Backup** to run the backup process.

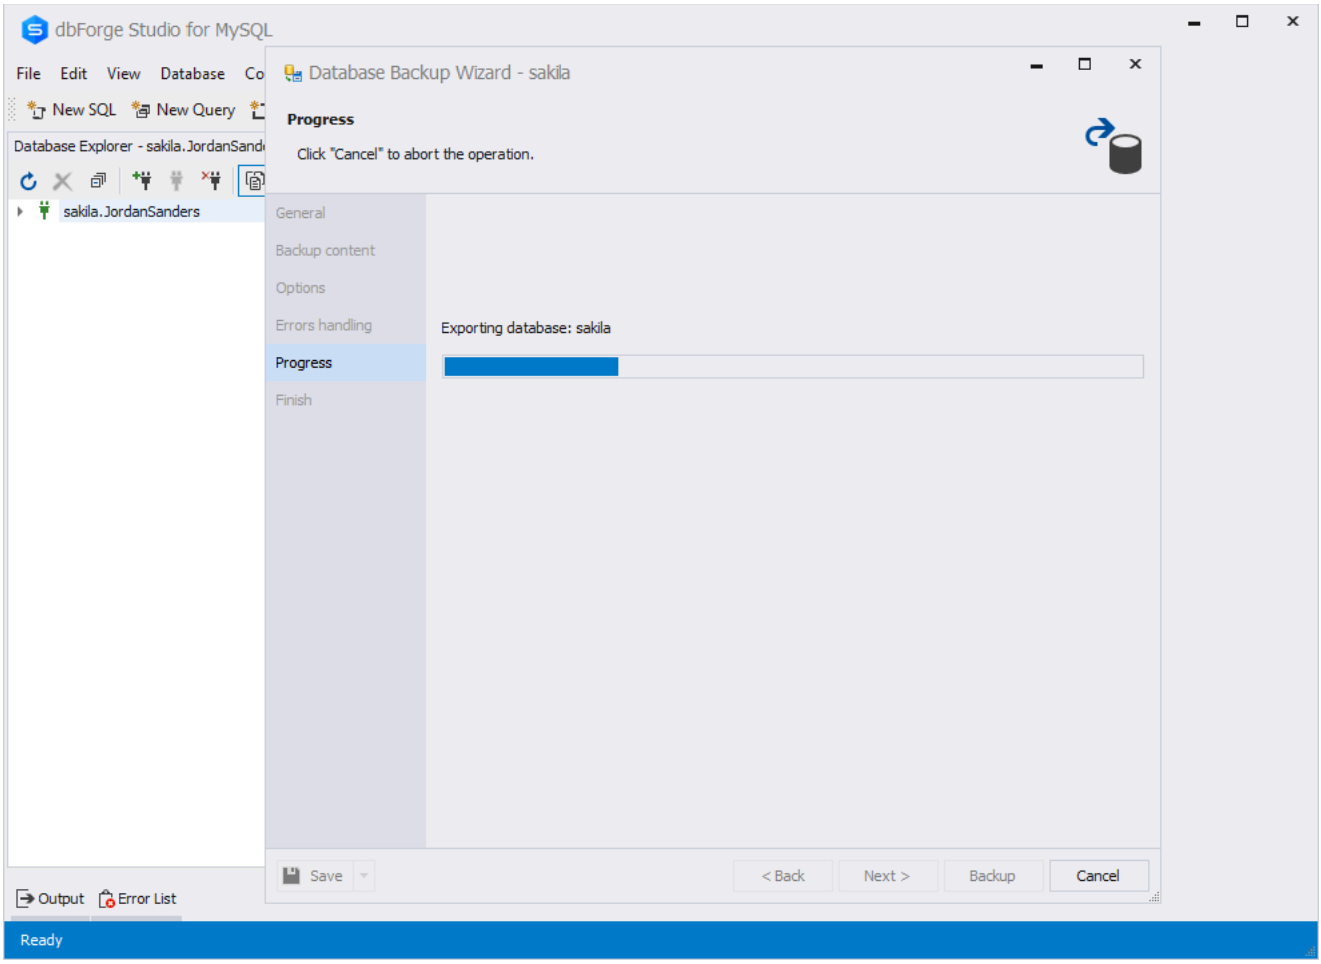
Note that you have two more options here: you can select **Save Project** to save your current backup project with all the settings—or you can select **Save Command Line** to save a backup script that you can execute from the command line whenever you need.



b4

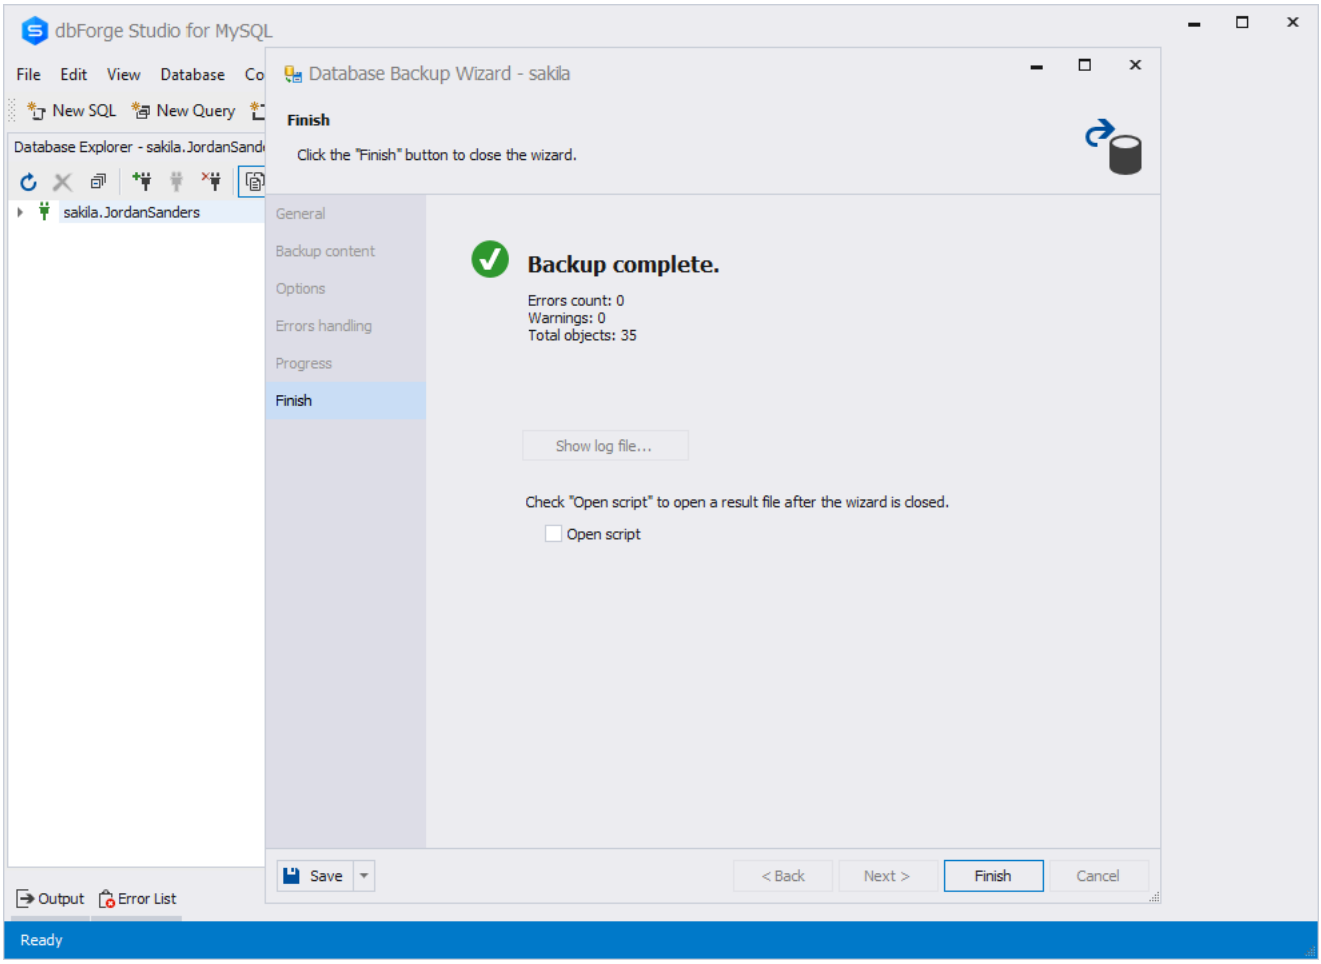
6. After you click **Backup**, wait for the backup process to be completed.

Note that you don't have to go through every wizard page to click **Backup**. You can do it whenever you've finished configuring your settings.



b5

7. Finally, confirm the successful completion by clicking **Finish**.



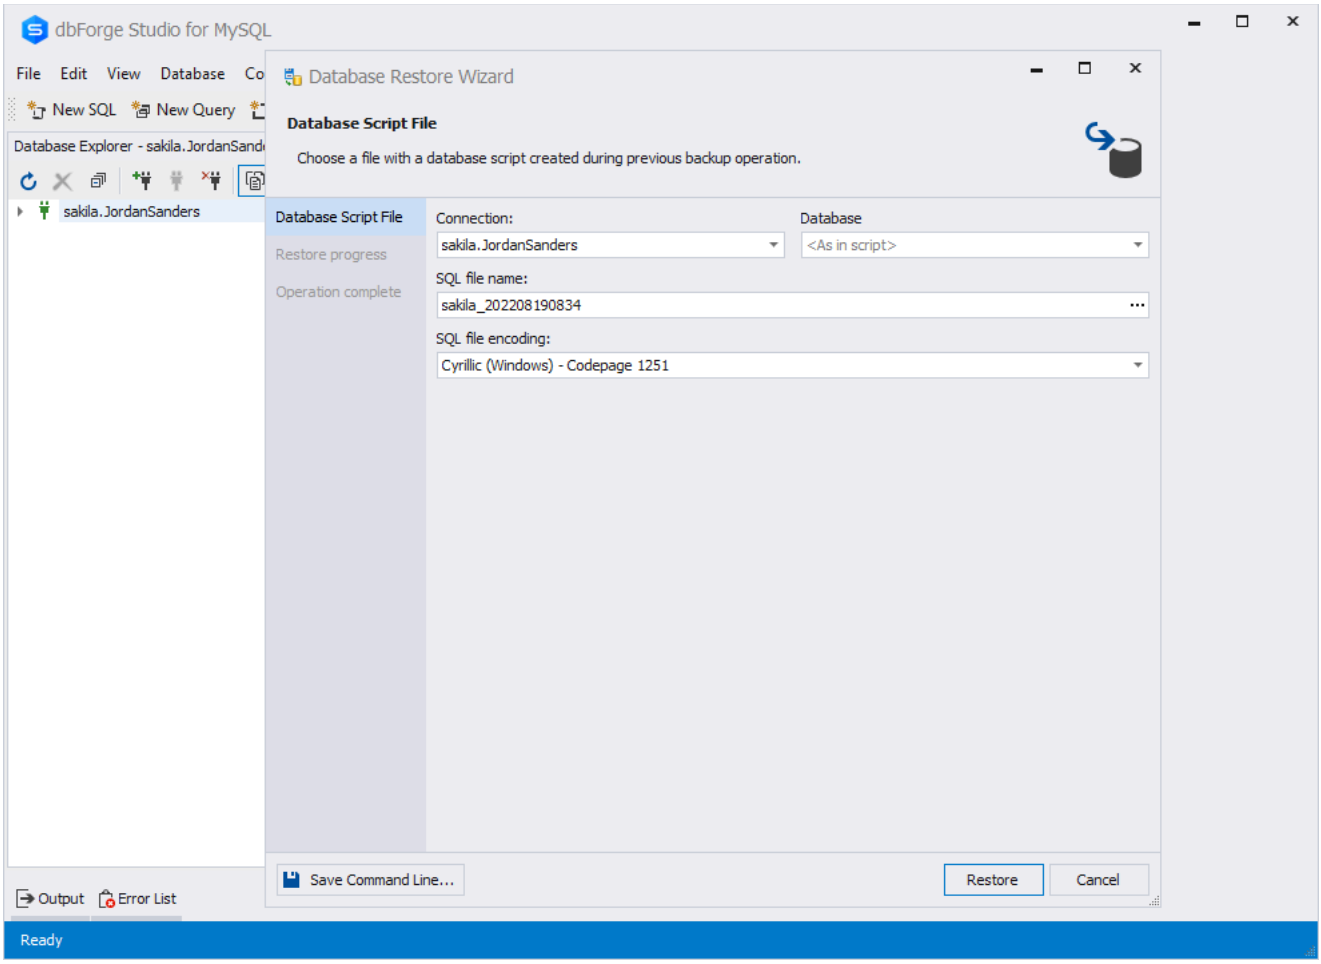
b6

As you can see, it's very easy. Furthermore, you can schedule to run regular backups using **Action > Create Basic Task** in **Windows Task Scheduler**.

Restore a MariaDB backup

This is an even faster task, done in half as many steps.

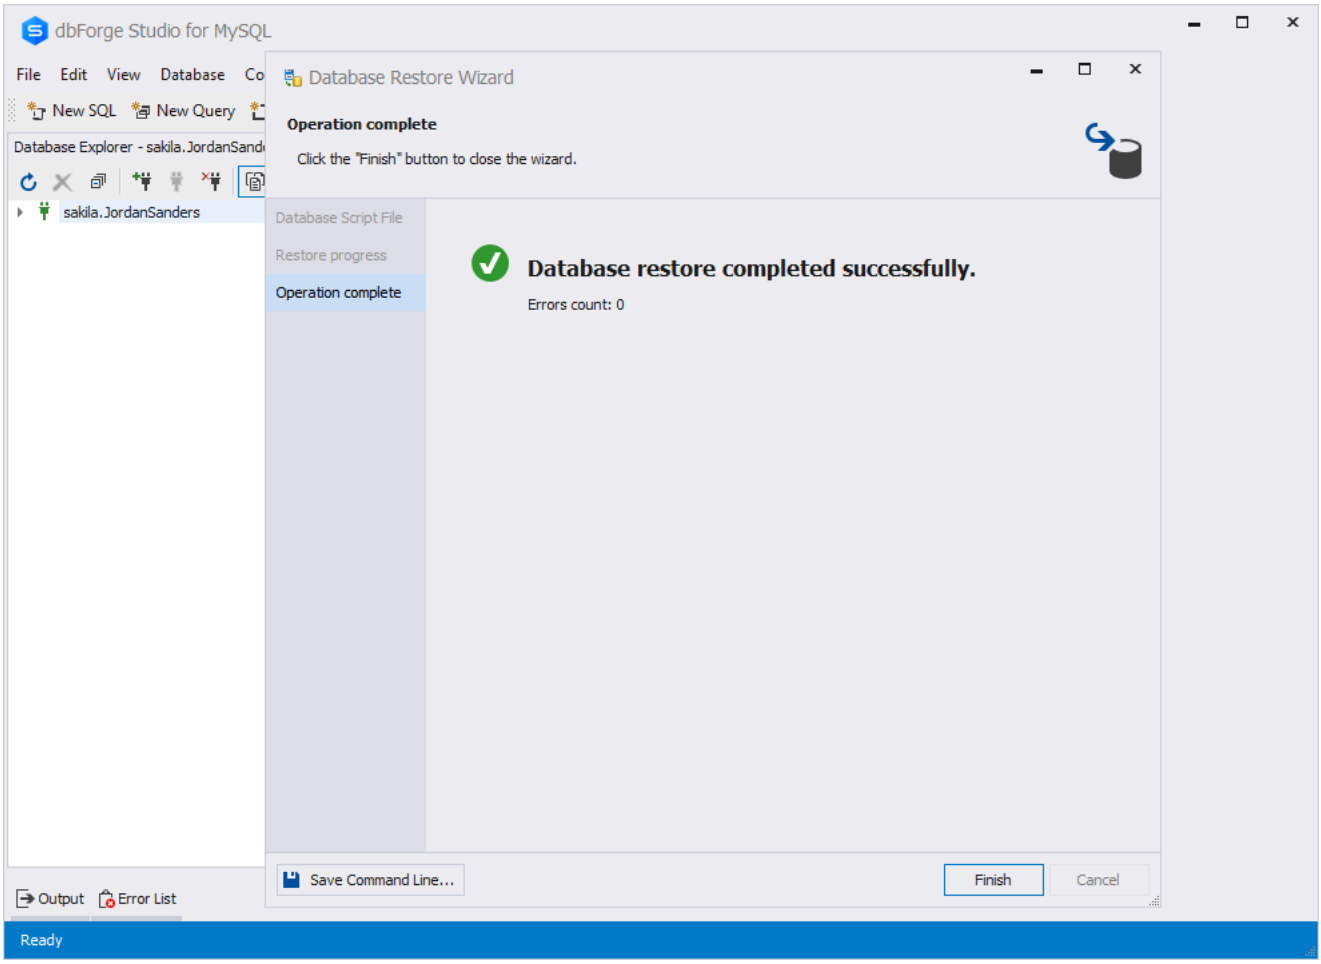
1. On the **Database** menu, go to ***Backup and Restore**, and click **Restore Database** to open the **Database Restore Wizard**.
2. On the **Database Script File** page, specify the required connection and database, as well as the path to the previously saved backup file.



r1

3. After that, click **Restore**, and let the Studio do the rest for you.

And when it's done, click **Finish**, and there you have it.



r2

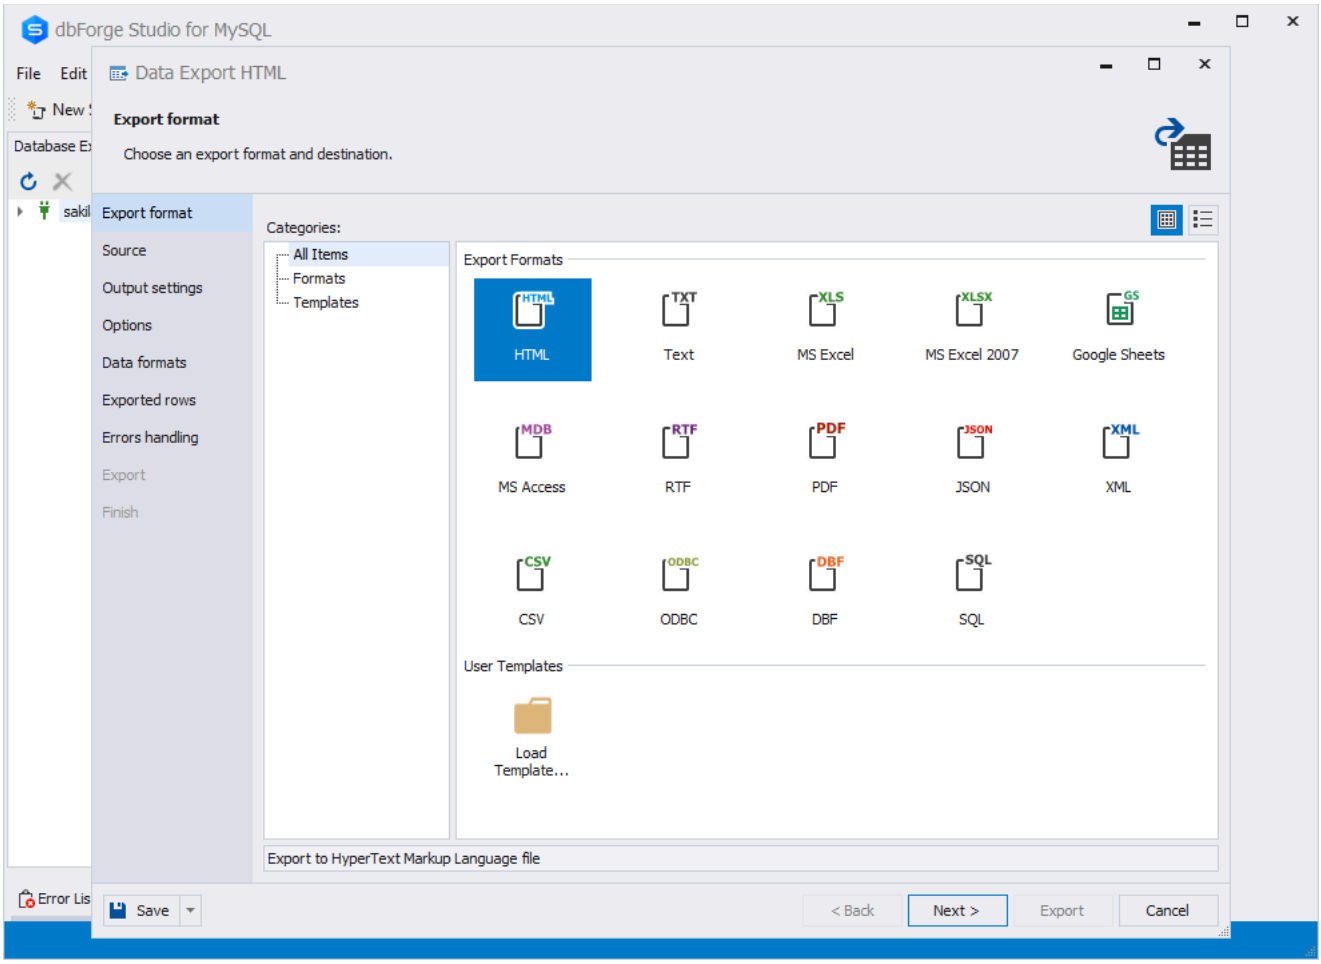
You can learn more about this functionality on the dedicated backup/restore page. Please note: while the page focuses on MySQL databases, everything that's described there is just as perfectly applicable to MariaDB from the same Studio with the same workflow.

Export data from MariaDB

With dbForge Studio, you can export data to 14 most popular formats: HTML, TXT, XLS, XLSX, MDB, RTF, PDF, JSON, XML, CSV, OBSC, DBF, SQL, and Google Sheets. You can do it with an easy-to-follow wizard that guides you through the entire process and delivers quite a few customization options.

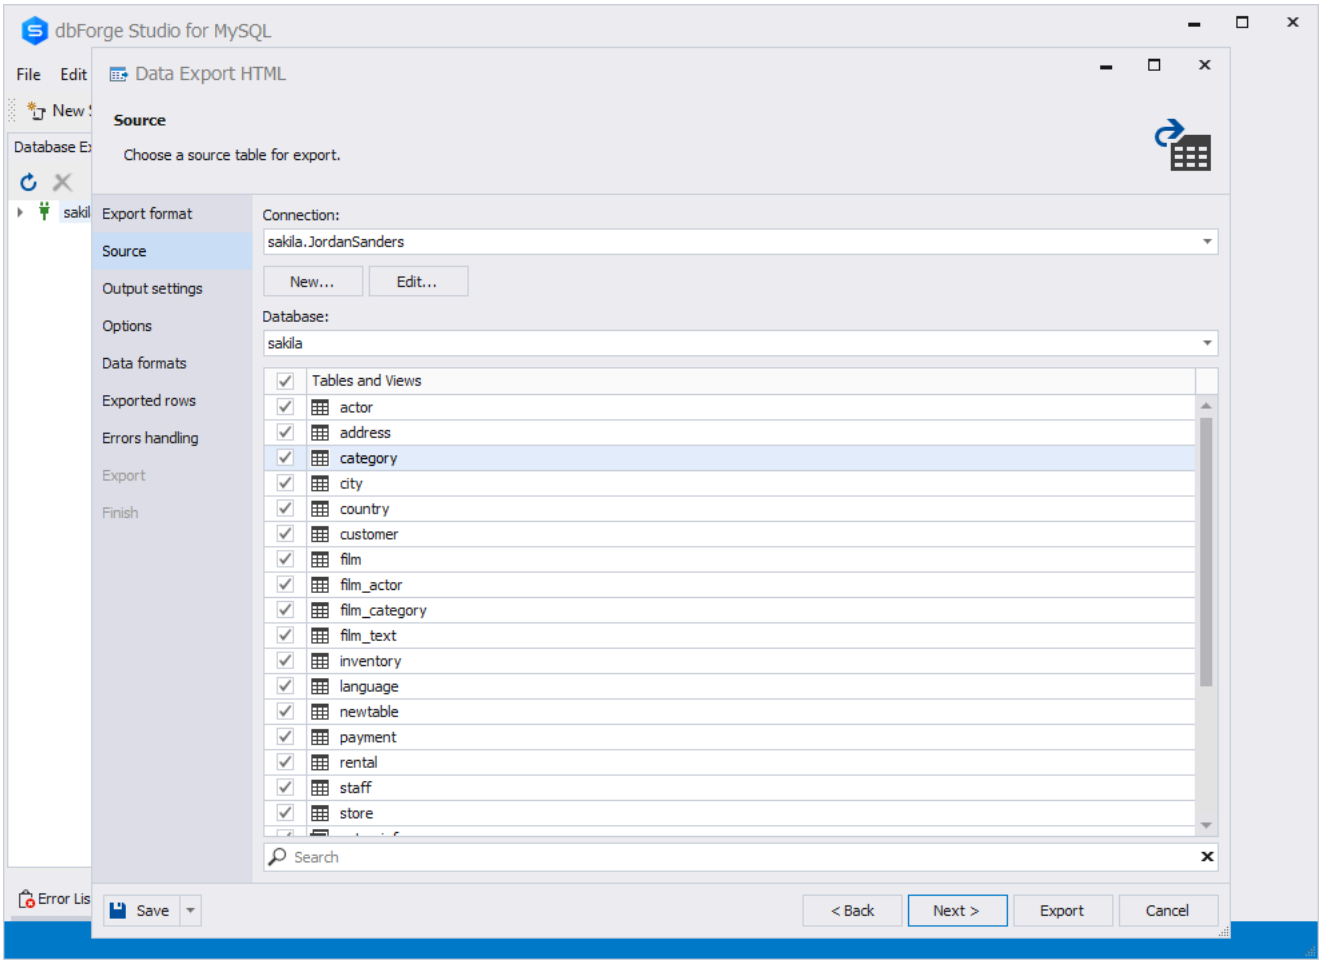
Let's see how it works. And before we start, note that different formats may have slightly different wizard pages. In our walkthrough, we'll take the HTML format as an example.

1. To open the export wizard, on the **Database** menu, click **Export Data**.
2. On the **Export format** page, pick the required format and click **Next**.



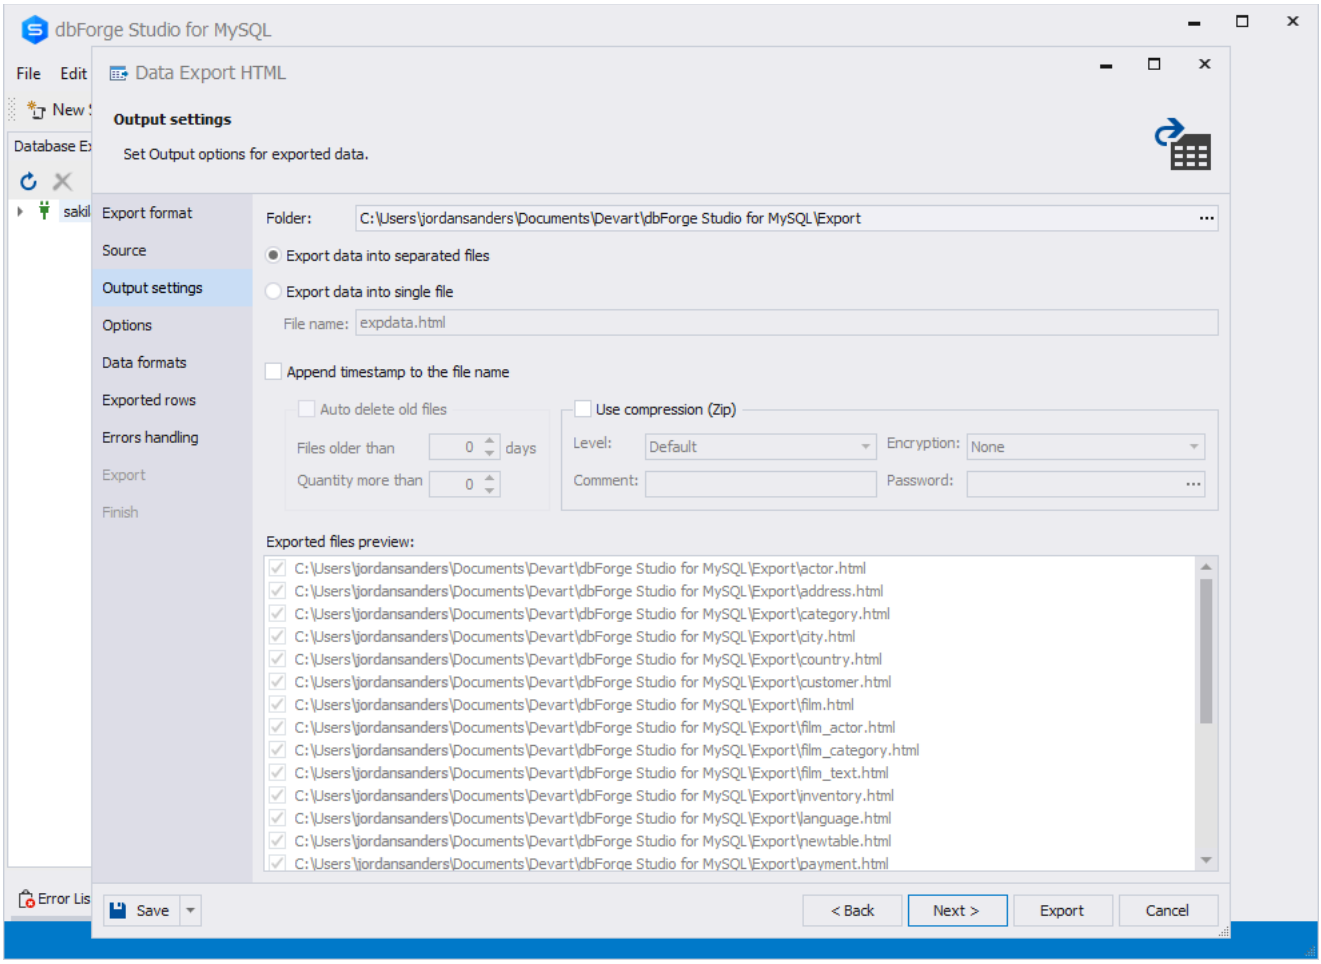
e1

3. On the **Source** page, select the required connection, database, as well as tables and views to be exported. Then click **Next**.



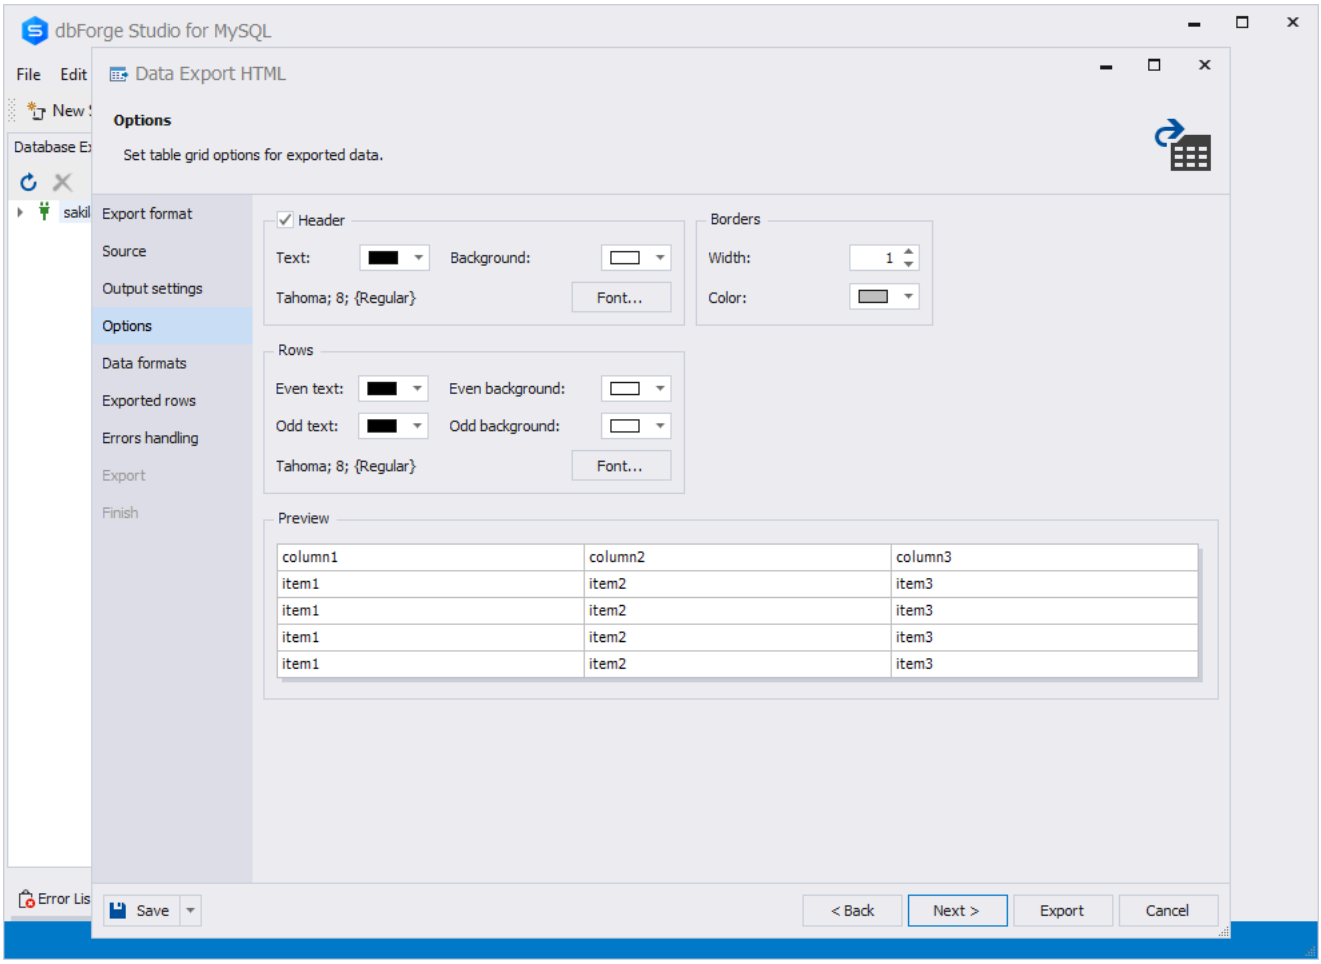
e2

4. On the **Output settings** page, specify the path for the output, select to export data into a single or several separate files, and configure a few other settings, such as timestamps and compression. Then click **Next**.



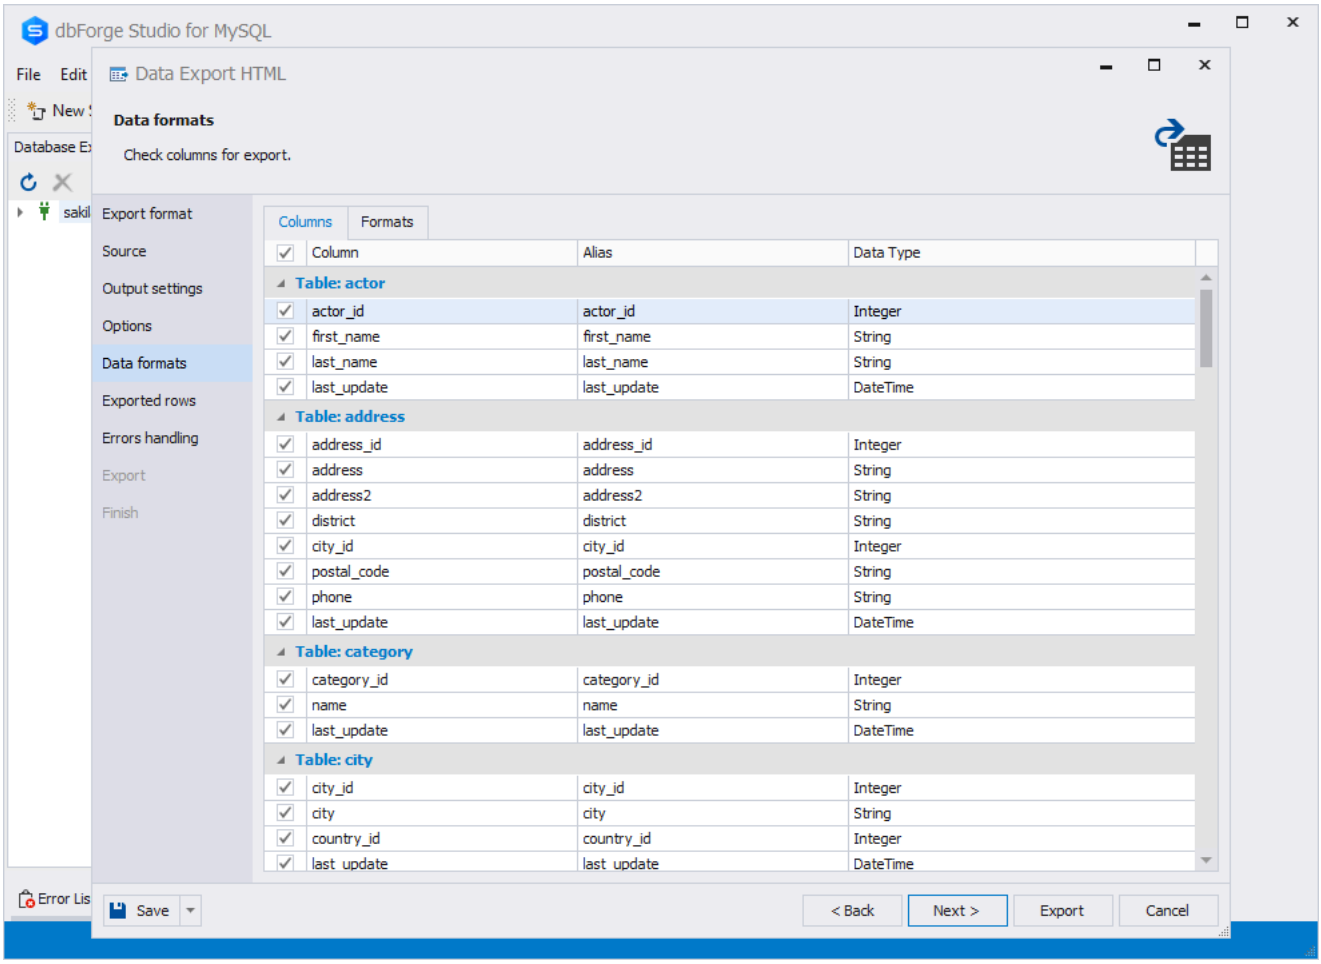
e3

5. On the **Options** page, configure and preview table grid options for exported data. Click **Next**.



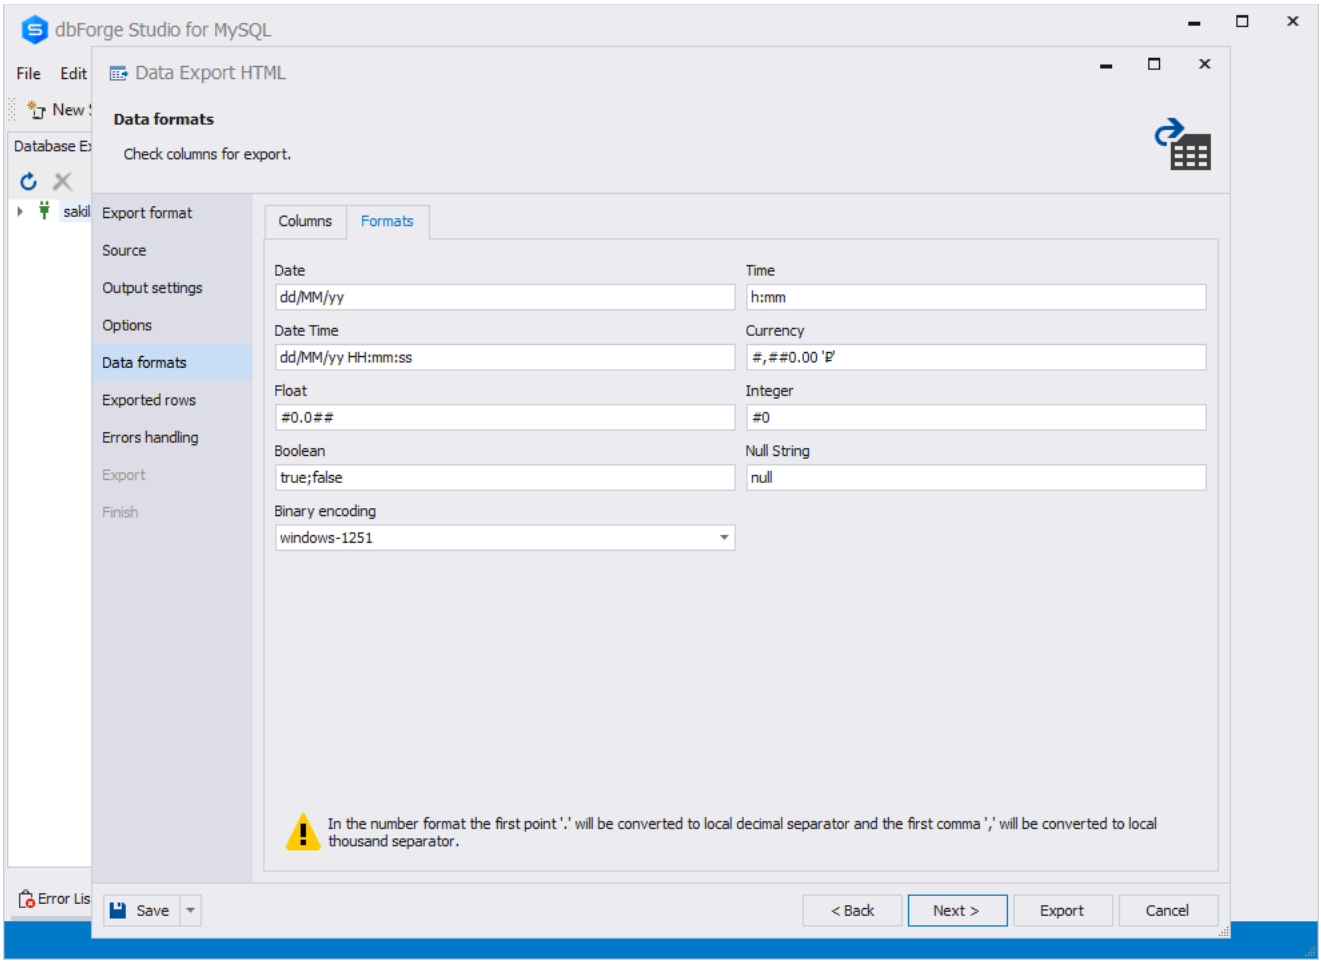
e4

6. On the **Data formats** page, you have two tabs. On the **Columns** tab, you can check the list of columns to be exported.



e5

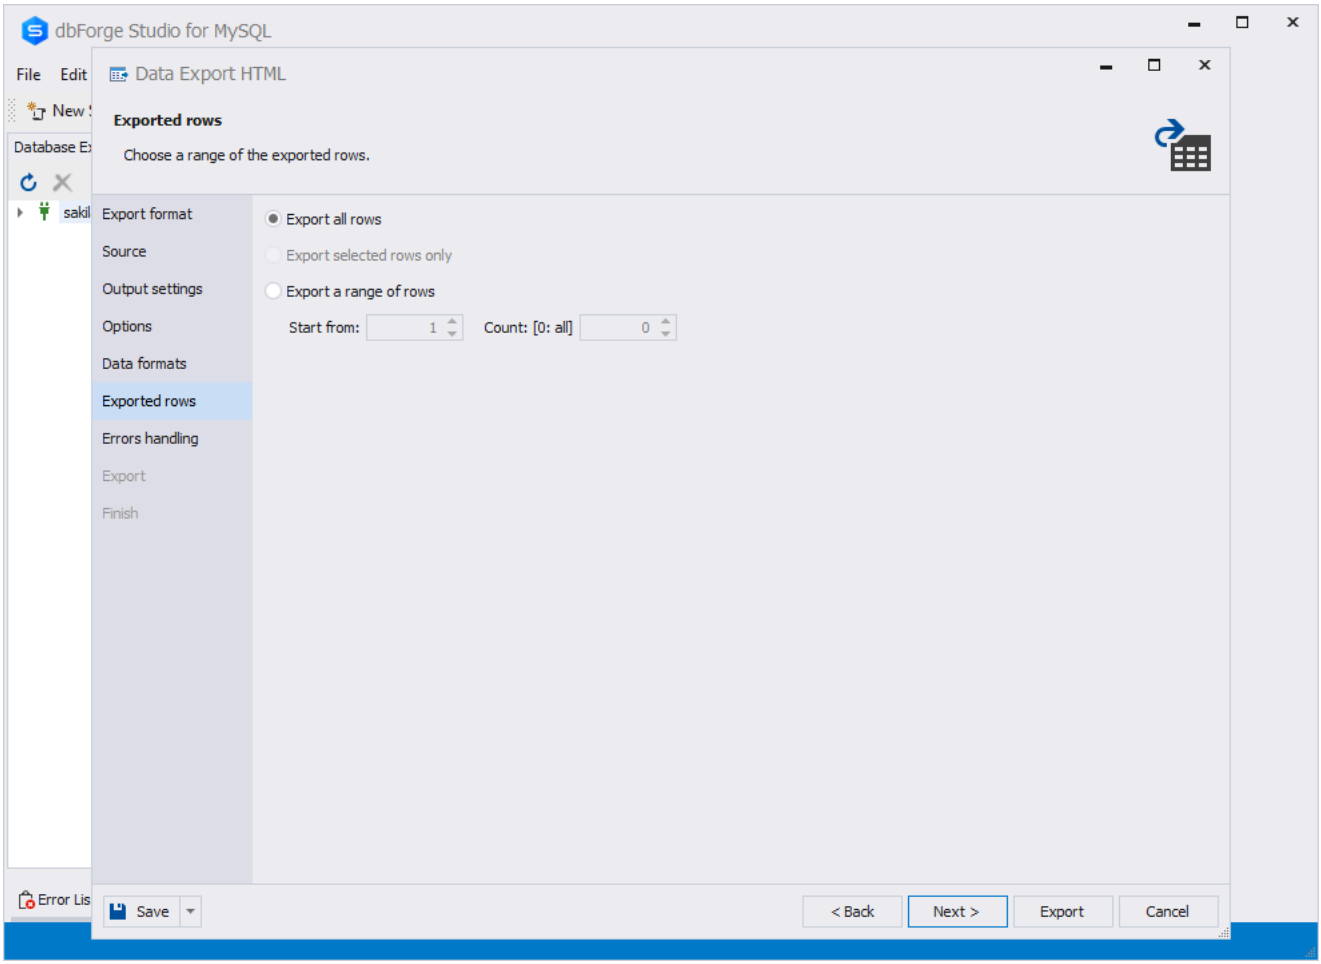
Then, on the **Formats** tab, you can adjust the default format settings for Date, Time, Date Time, Currency, Float, Integer, Boolean, Null String, as well as select the required binary encoding.



e6

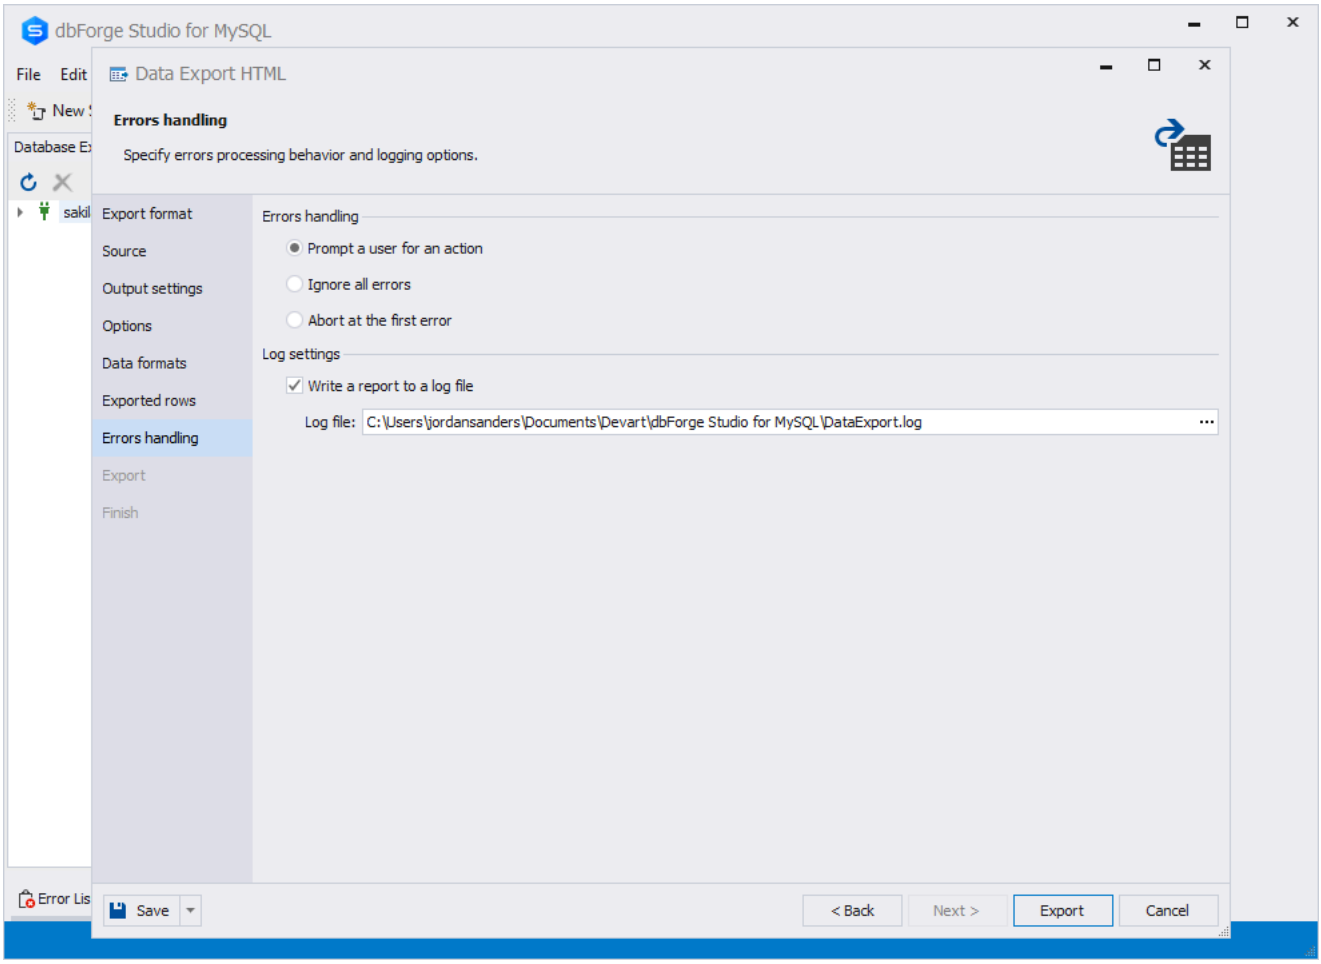
Once you make sure everything is correct, click **Next**.

7. On the **Exported rows** page, select to export all rows or define a certain range of rows, and then click *Next*.**



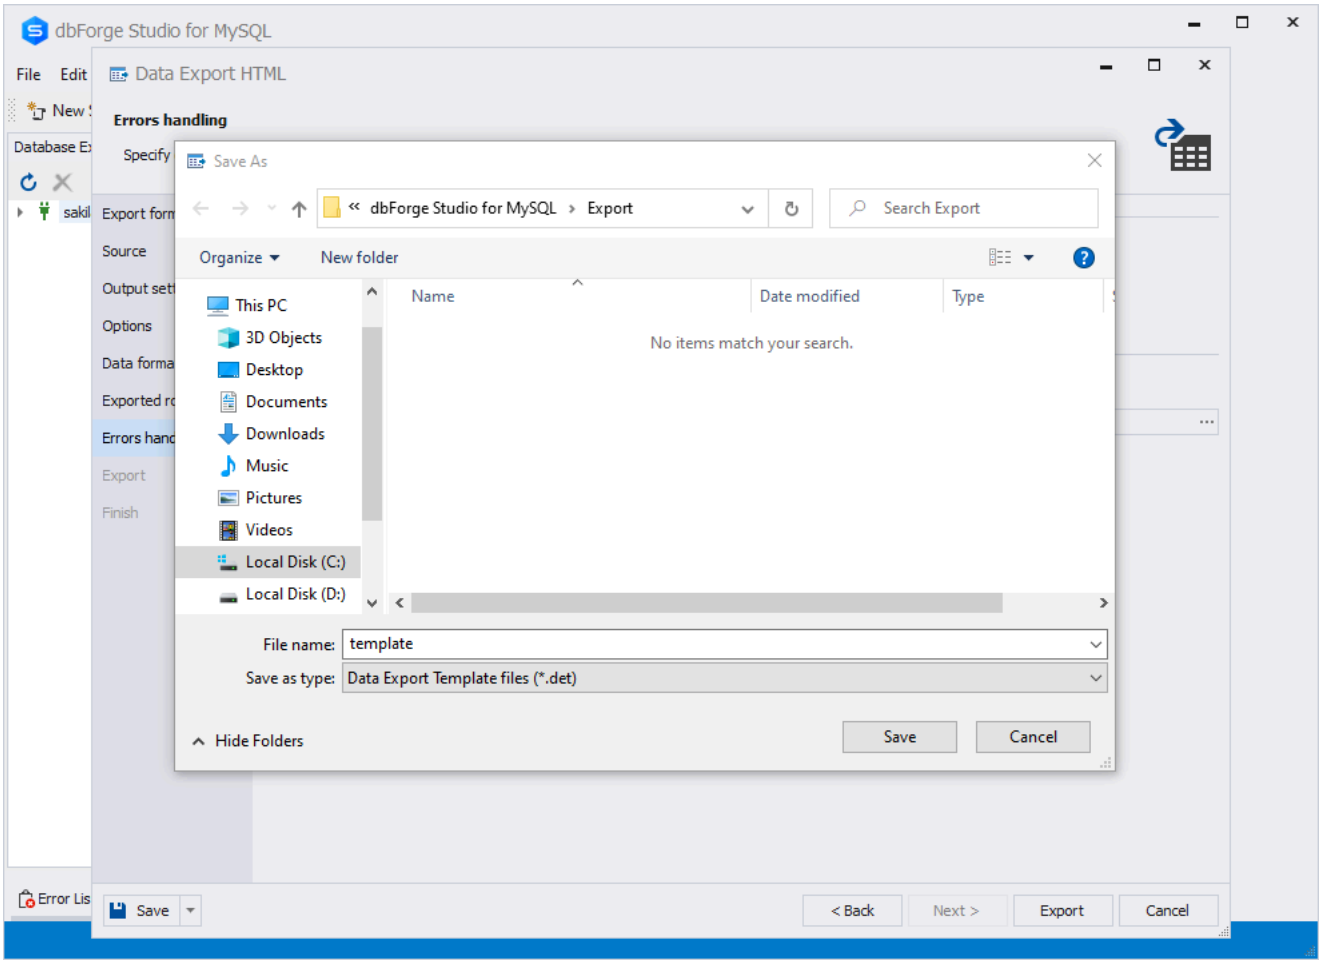
e7

8. On the **Errors handling** page, configure the errors handling behavior and select to keep a log file, if necessary.



e8

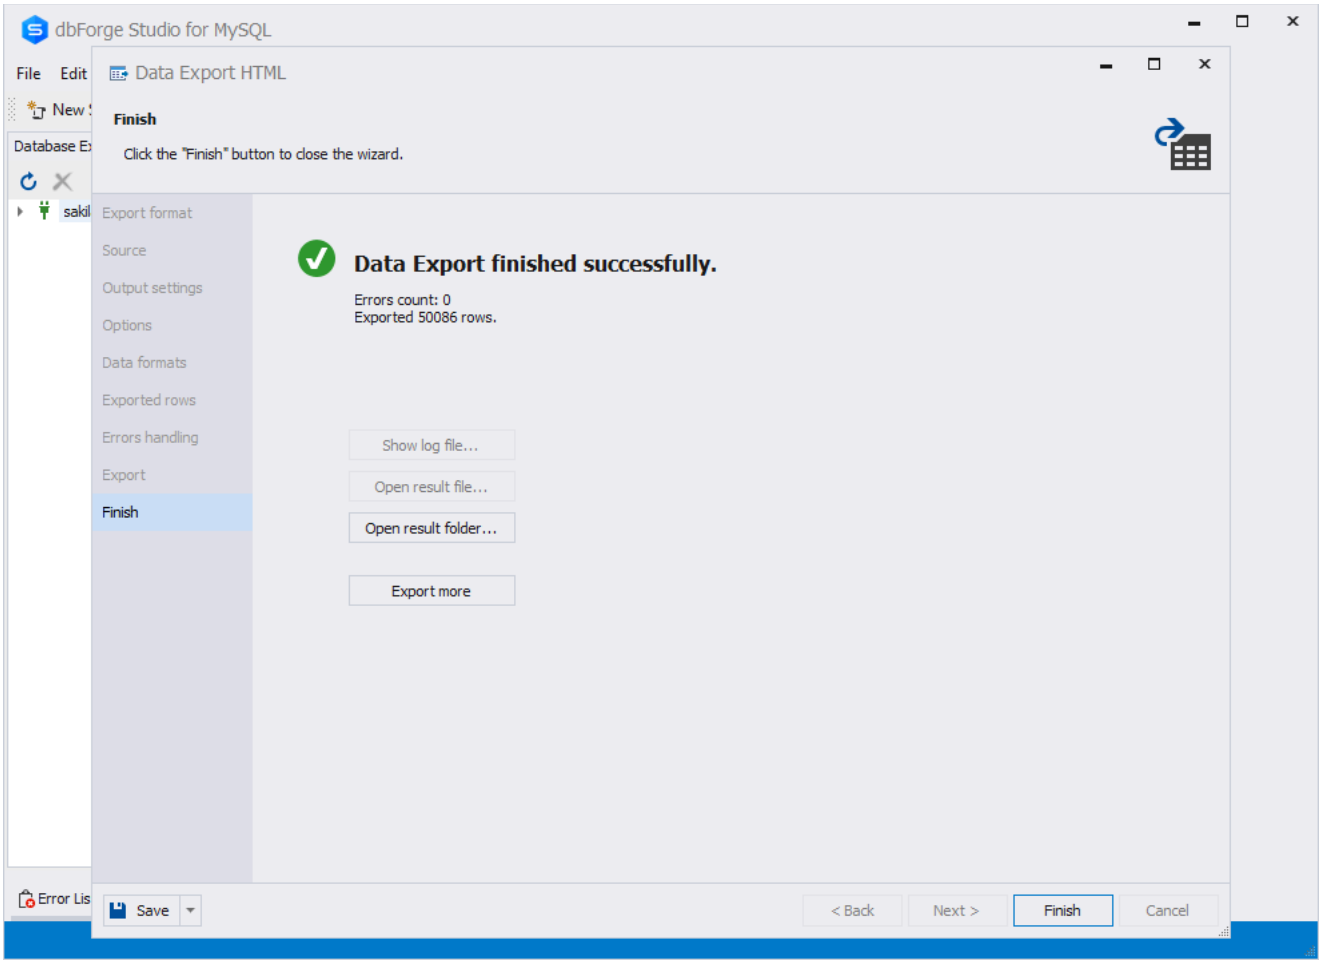
But before you click **Export**, note that you can save templates with your settings for recurring export operations. To do that, click **Save** in the lower left corner of the wizard, specify a name and a destination for the template file to be saved to, and then click **Save**.



e9

Also note that you don’t have to go through every wizard page to click **Export**. You can do it whenever you’ve finished configuring your settings.

9. Finally, after you click **Export**, watch the progress and click **Finish** upon completion.



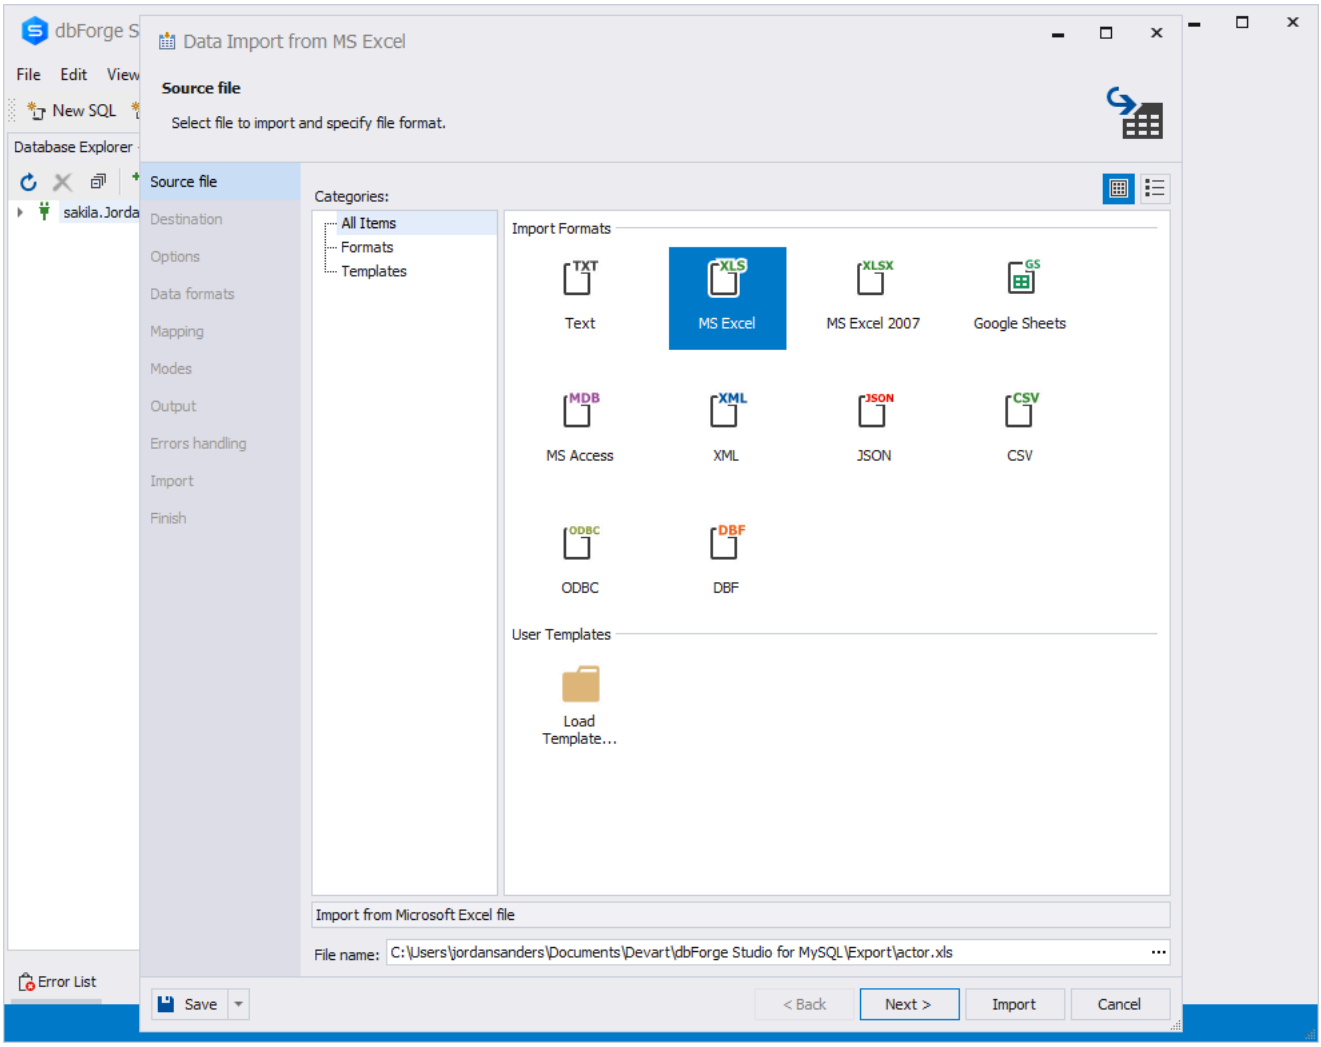
e10

Done! Now, if you want, you can open the folder with the output file right away.

Import data into MariaDB

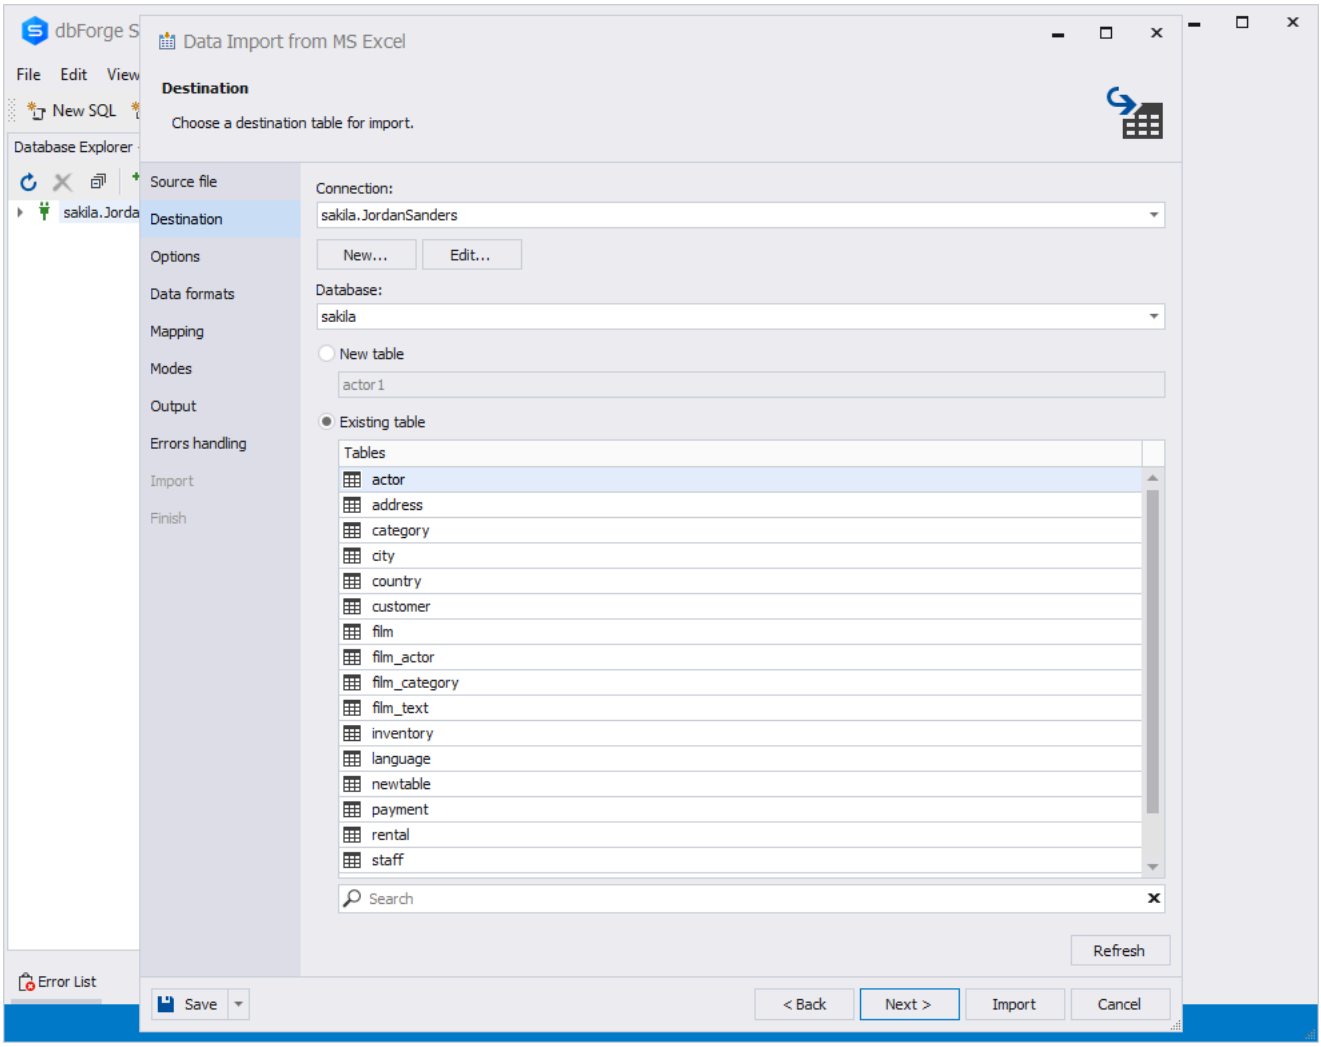
dbForge Studio supports 10 data formats for import, including TXT, XLS, XLSX, MDB, XML, JSON, CSV, ODBC, DBF, and Google Sheets. Just like with export, you have a helpful wizard at hand, whose pages may have differences, depending on the format. And let's pick a different format this time, say, the Microsoft Excel format (XLS).

1. To open the wizard, on the **Database** menu, click **Import Data**.
2. On the **Source file** page, choose the required format, select the file to import data from, and click **Next**.



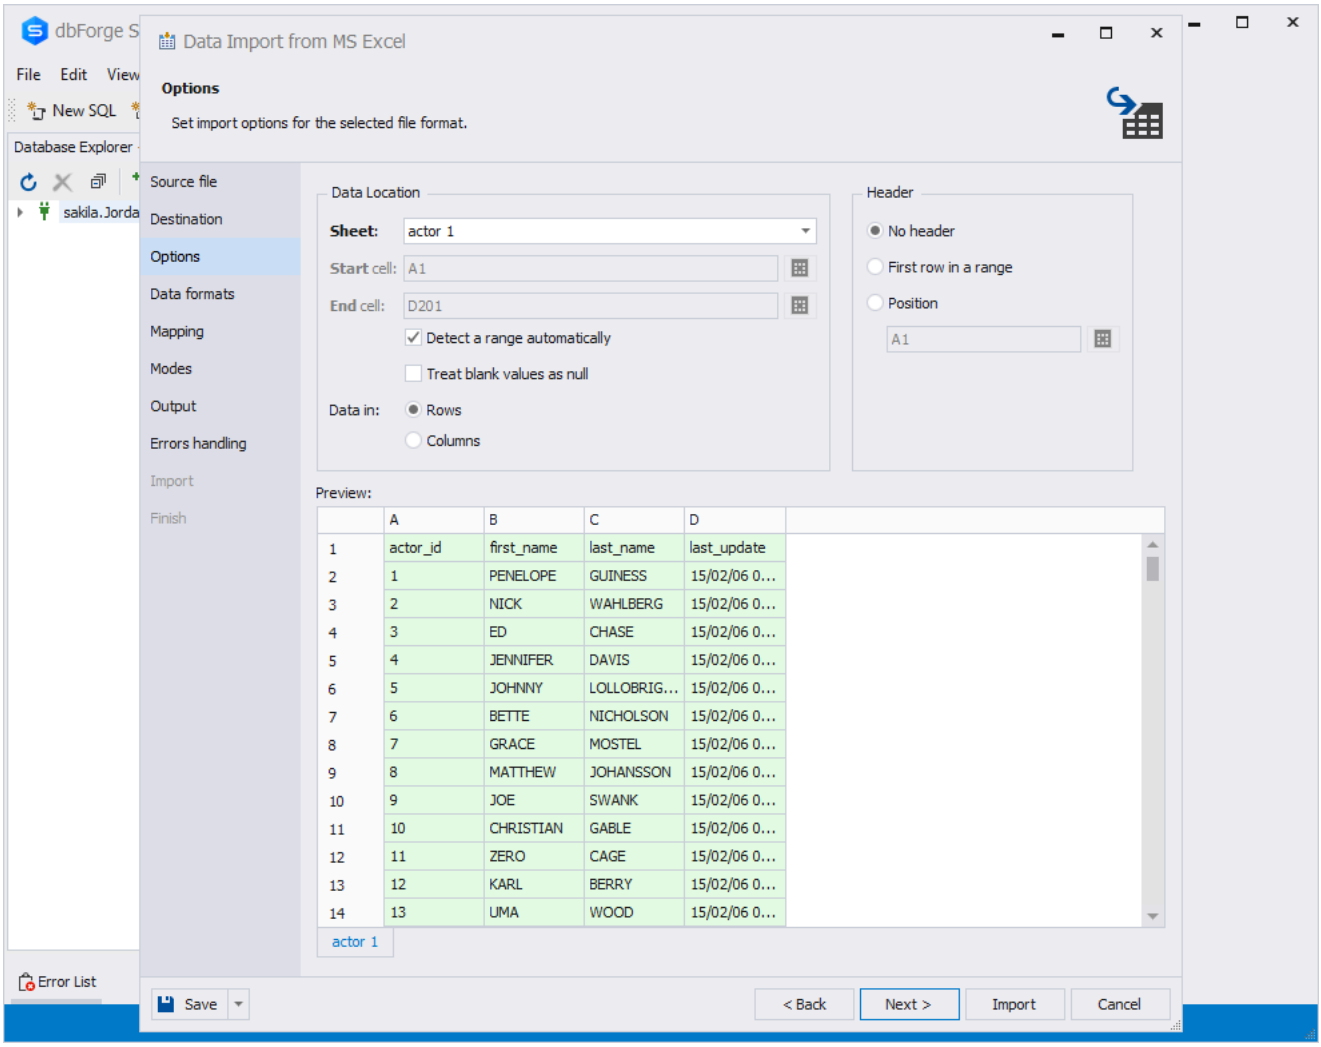
i1

3. On the **Destination** page, select the target connection and database. Then you can select to import data either to a new table or to an existing table. Click **Next**.



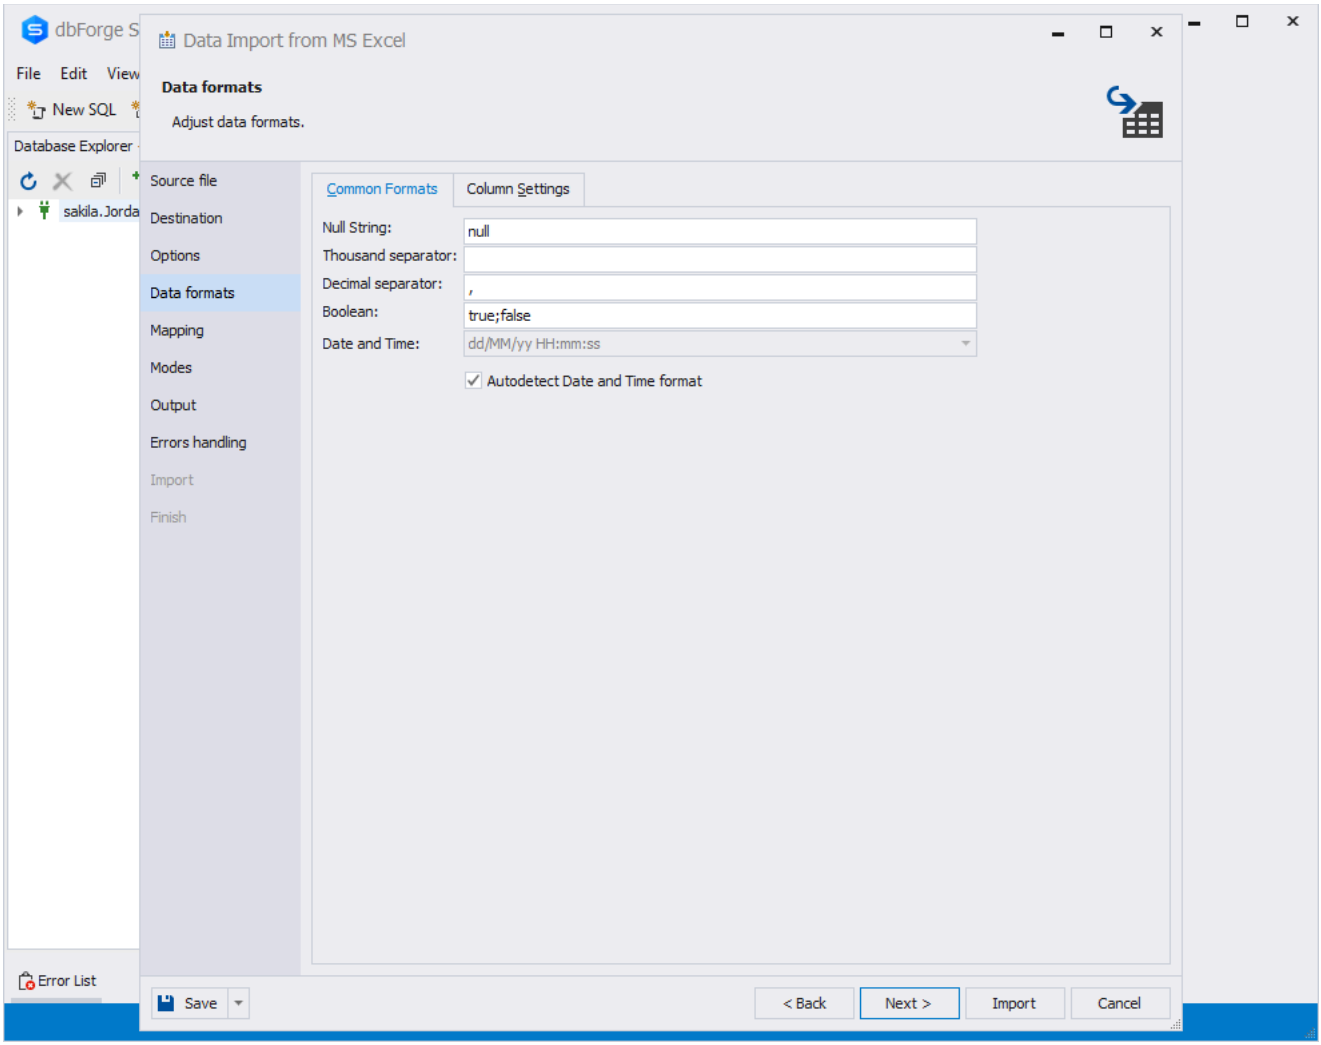
i2

4. On the **Options** page, configure and preview table grid options for imported data. Click **Next**.



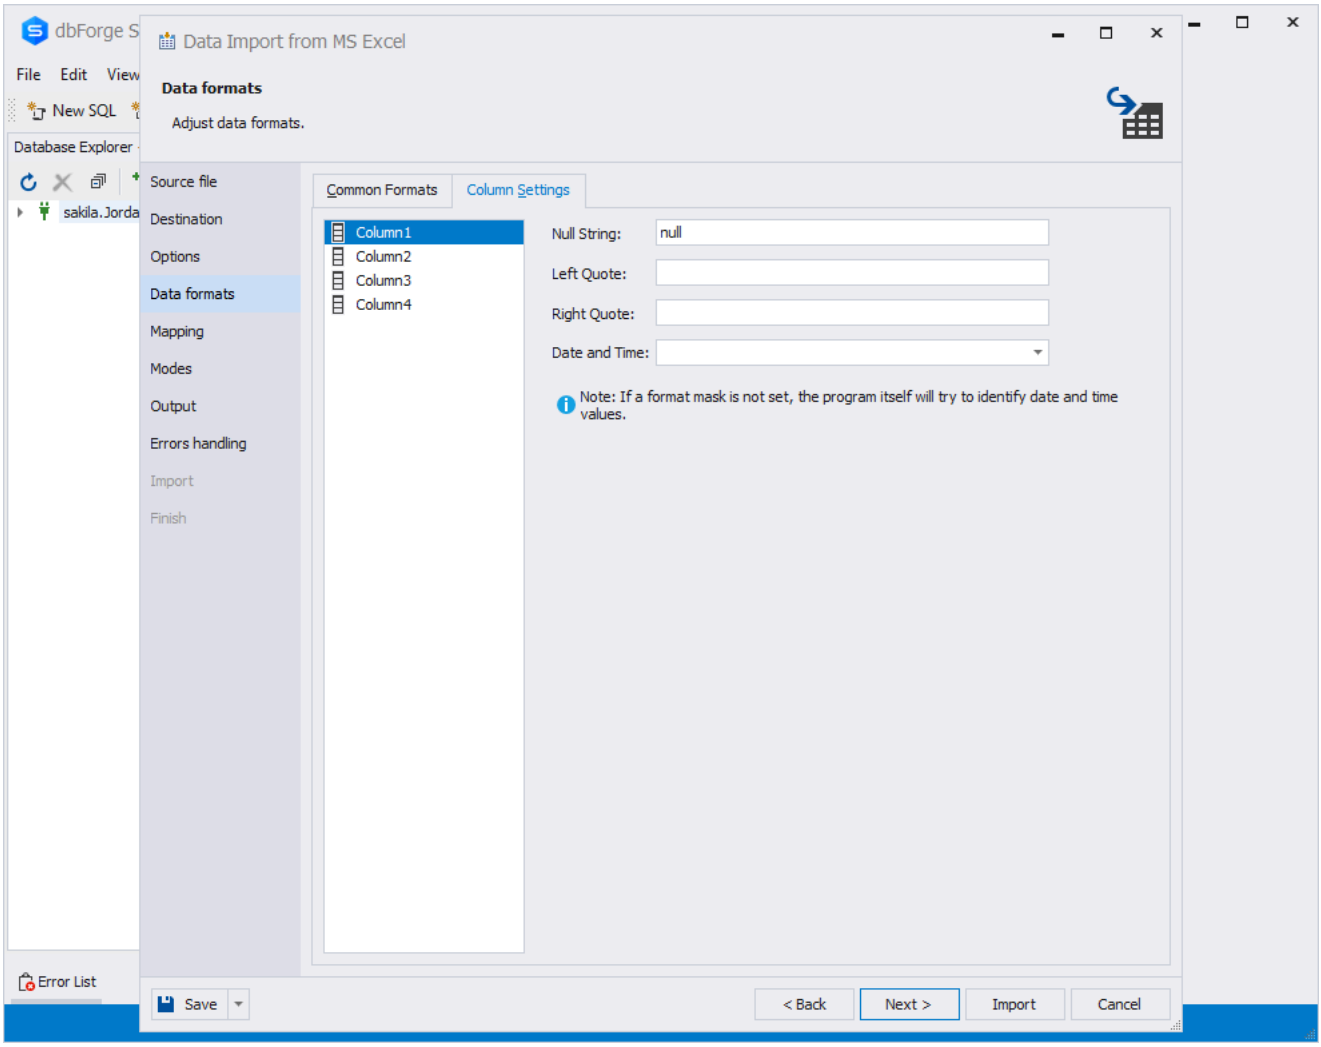
i3

5. On the **Data formats** page, you have two tabs. The first tab is called **Common Formats**, where you can specify the required formats for null strings, thousand and decimal separators, boolean variables, date and time.



i4

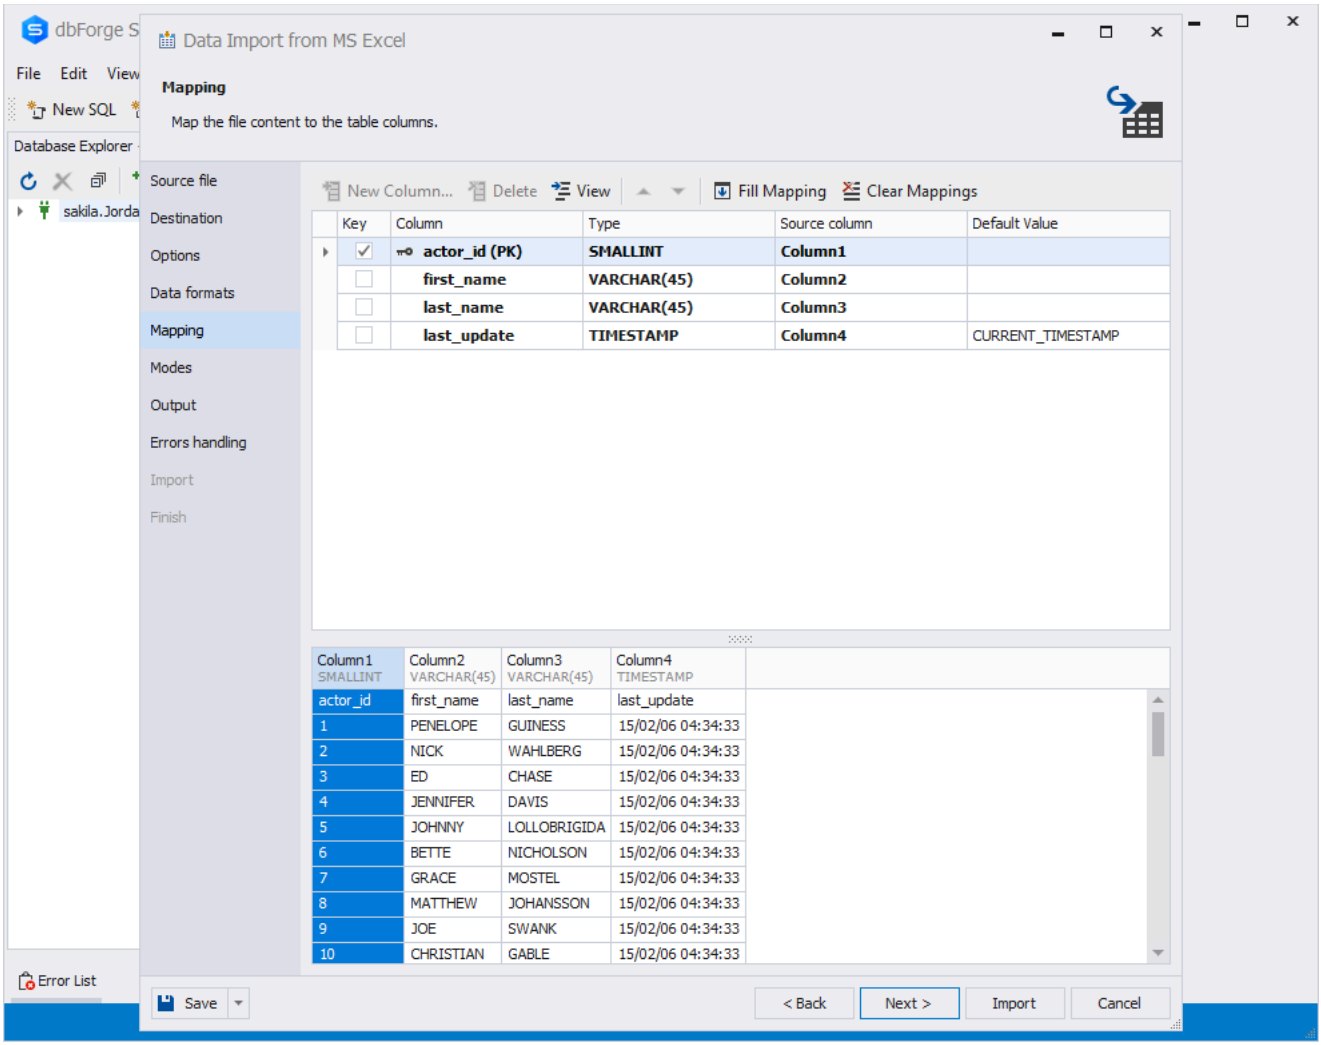
The second tab is called **Column Settings**, where you can configure format settings for separate columns.



i5

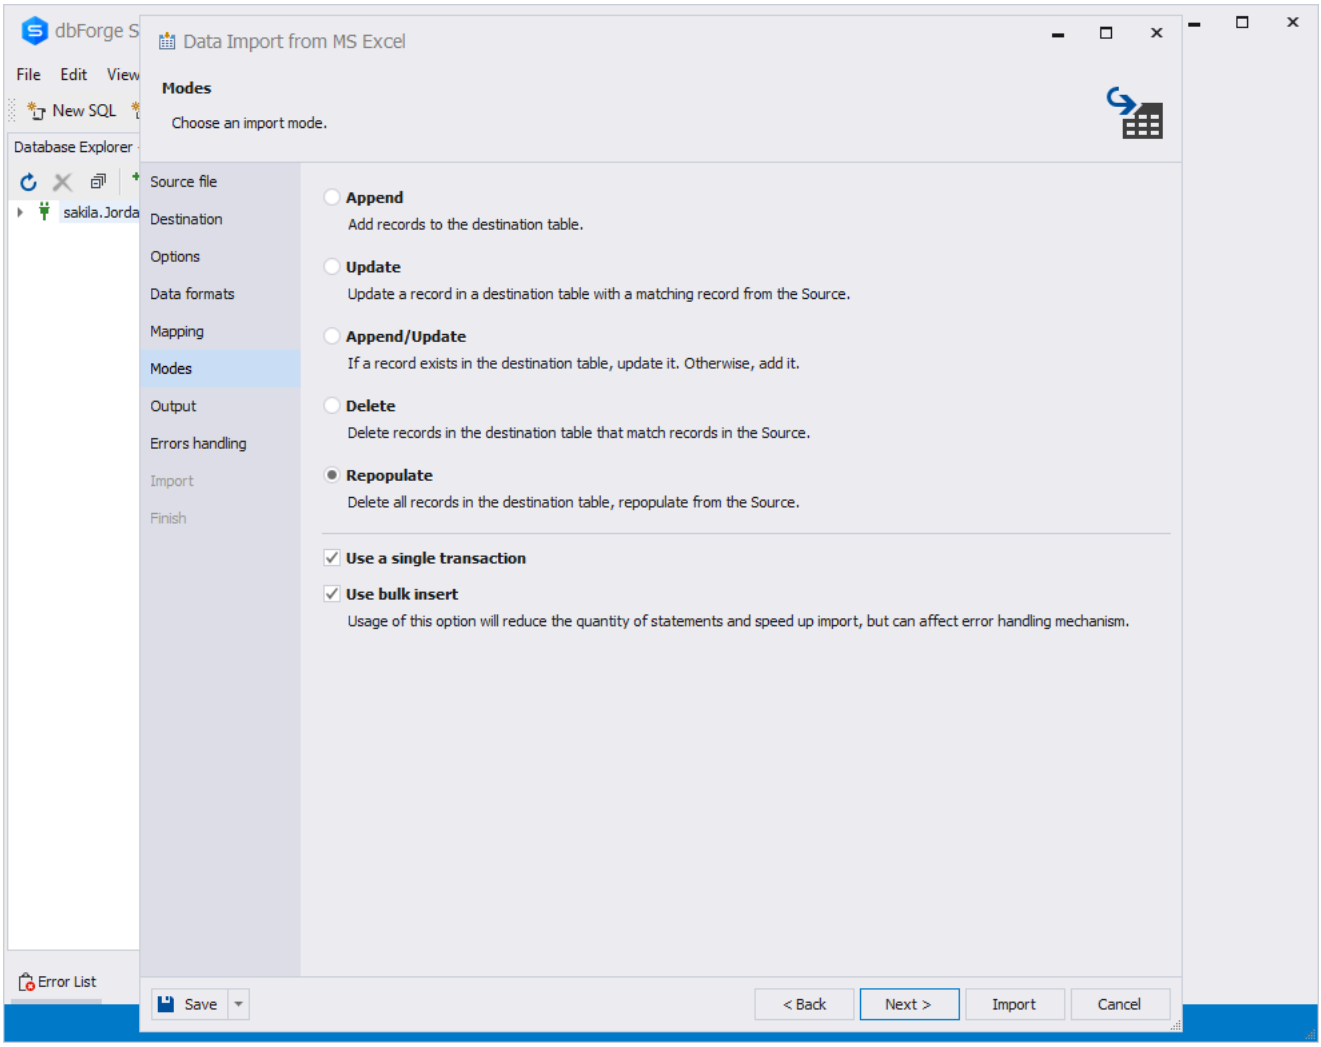
Once you make sure everything is correct, click **Next**.

6. On the **Mapping** page, you can map the source columns to the target ones and preview the results. If you're importing data into a new table, the Studio will automatically create and map all the columns, so you will only have to make adjustments if you wish. Then click **Next**.



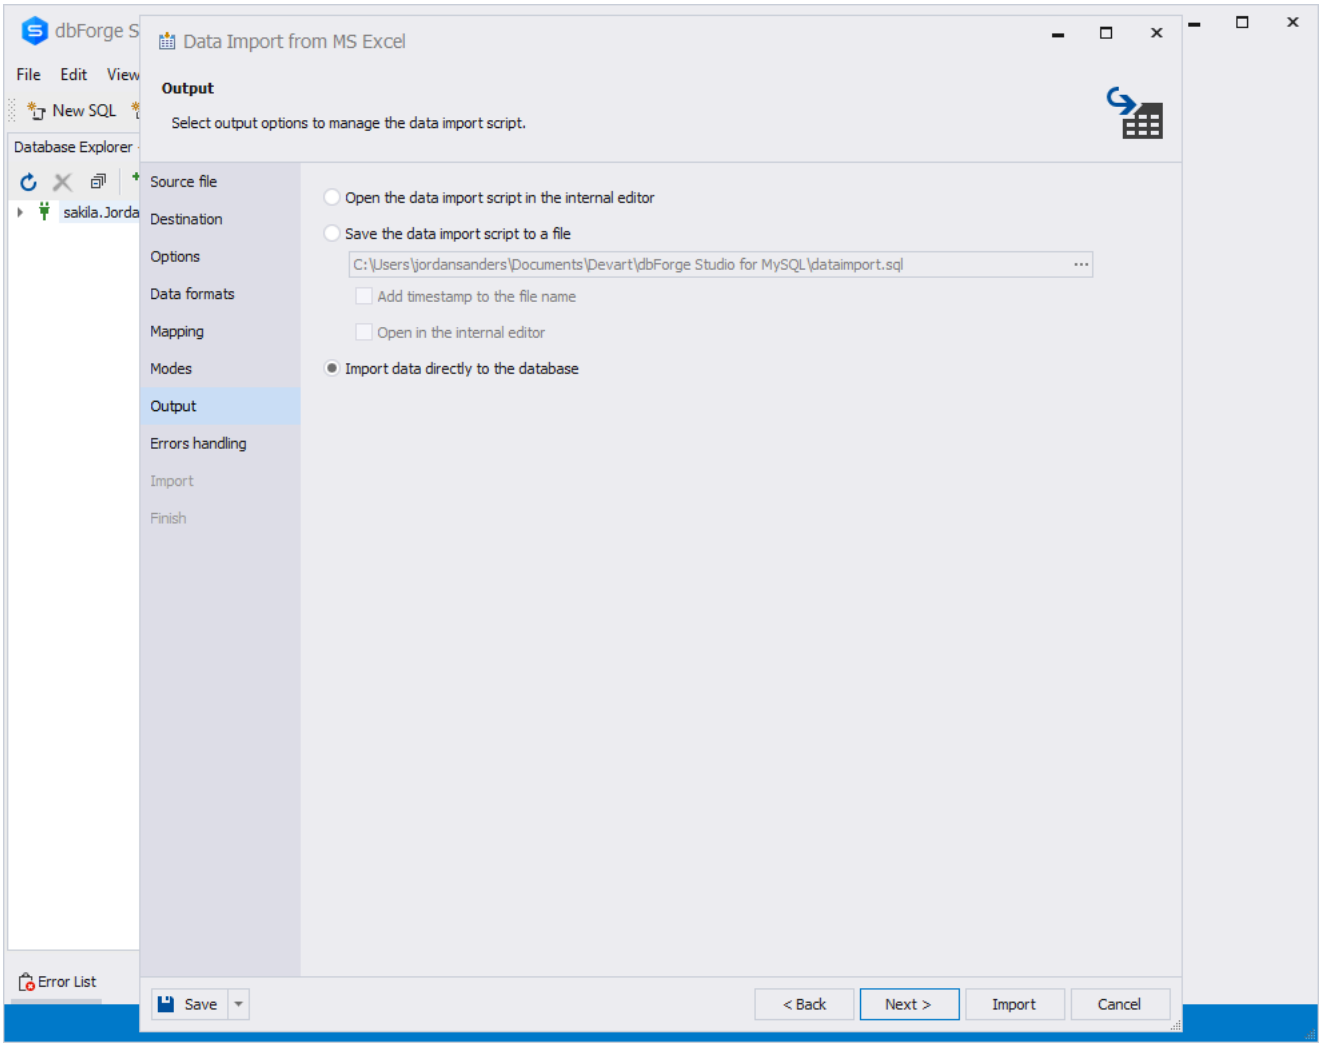
i6

7. On the **Modes** page, select one of the 5 available import modes and click **Next**.



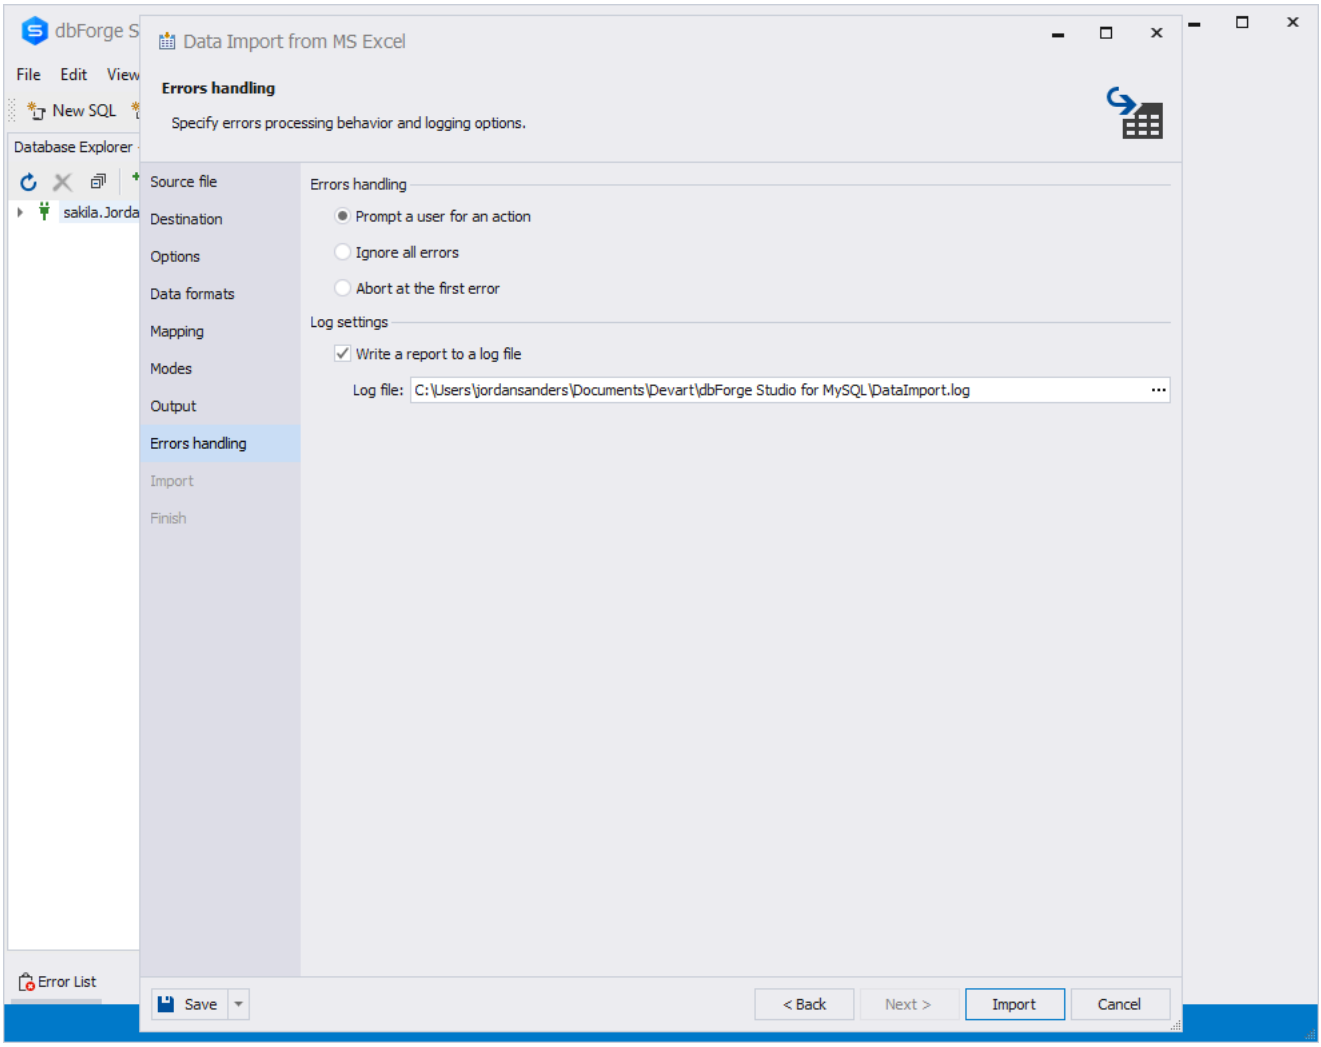
i7

8. On the **Output** page, select the preferred output option and click **Next**.



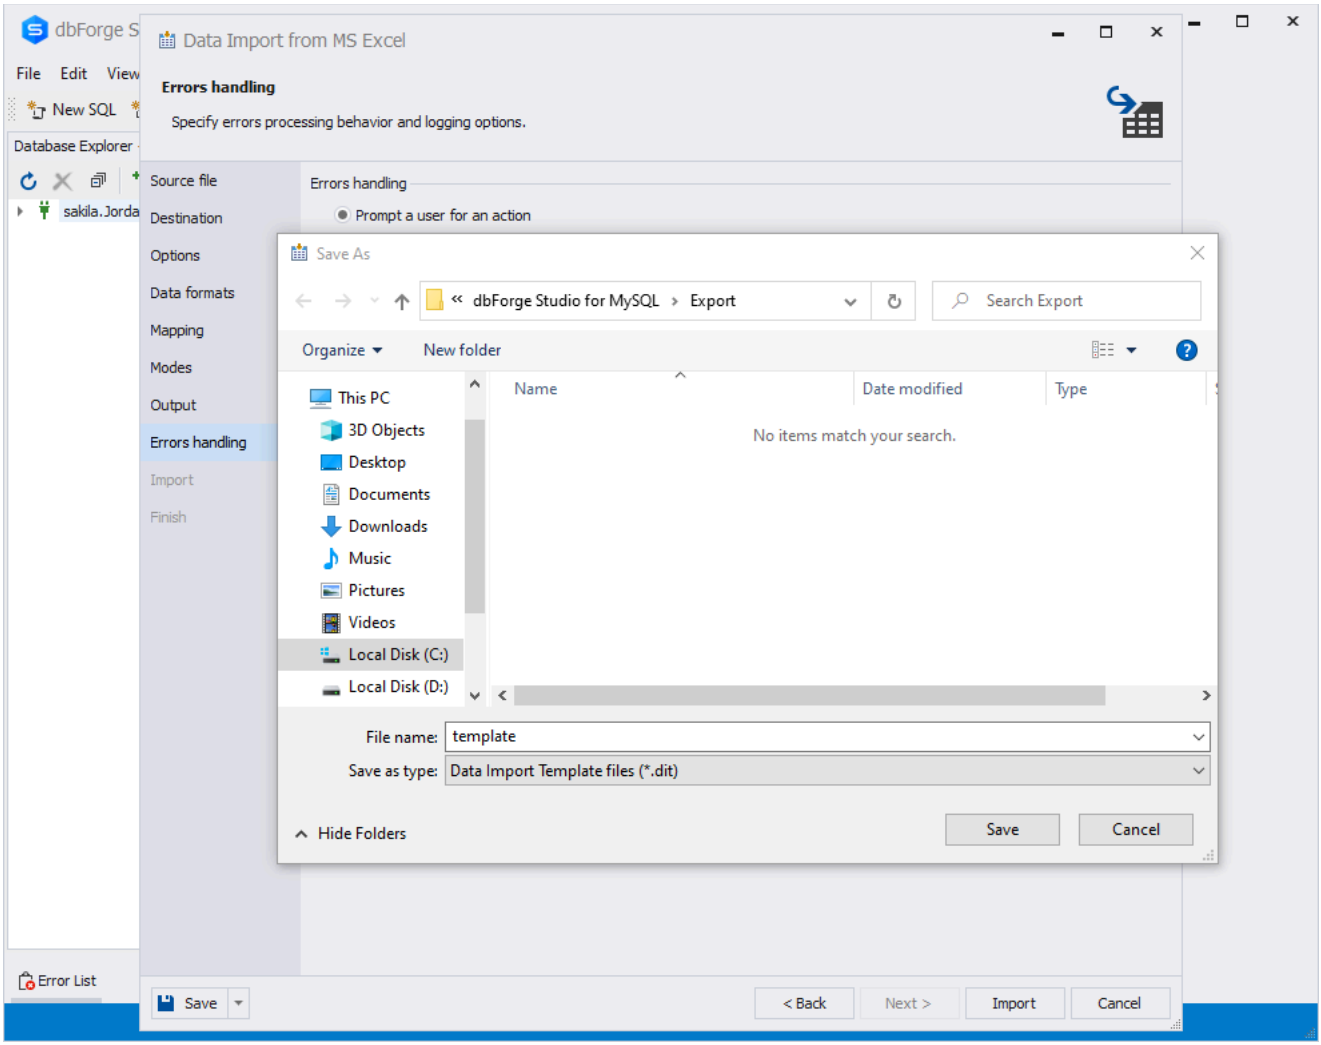
i8

9. On the **Errors handling** page, configure the errors handling behavior and select to keep a log file, if necessary.



i9

Similarly to export, you can save templates with your settings for recurring import operations. To do that, click **Save** in the lower left corner of the wizard, specify a name and a destination for the template file to be saved to, and then click **Save**.



i10

Also note that you don't have to go through every wizard page to click **Import**. You can do it whenever you've finished configuring your settings.

10. After you click **Import**, wait for the process to be completed. Then click **Finish** to confirm the successful completion, and check the results if you wish. That's it!

You can learn more about this functionality on the dedicated data export/import page. Please note: while the page focuses on MySQL databases, everything that's described there is just as perfectly applicable to MariaDB from the same Studio with the same workflow.

There is much more to dbForge Studio when it comes to MariaDB development and management. You can have a brief overview of its features and capabilities on the Features page.

That said, if you'd love to have a single IDE that doesn't need any 3rd-party extensions because it can perfectly deal with nearly any task on its own, feel free to download dbForge Studio for a free 30-day trial and give it a go in your daily work.

mariadb-install-db

> **Warning:**
>
> **This page is for the `mariadb-install-db` script for Linux/Unix only.**
>
> For the Windows-specific tool of similar name and purpose, see Installing System Tables on Windows.
>
> The Windows version shares the common theme (creating system tables), yet has a lot of functionality specific to Windows systems, for example creating a Windows service. The Windows version does *not* share command line parameters with the Unix shell script.

`mariadb-install-db` initializes the MariaDB data directory and creates the system tables in the mysql database, if they do not exist.

> **Note:**
>
> Previously, the client was called `mysql_install_db` . It can still be accessed under this name, via a symlink in Linux, or an alternate binary in Windows.

MariaDB uses these tables to manage privileges, roles, and plugins. It also uses them to provide the data for the help command in the mariadb client.

`mariadb-install-db` works by starting MariaDB Server's `mariadbd` process in –bootstrap mode and sending commands to create the system tables and their content.

Usage

Invoke `mariadb-install-db` using the following syntax:

```
$ mariadb-install-db [options]
```

Because the MariaDB server (`mariadbd`) needs to access the data directory when it runs, you should either run `mariadb-install-db` from the same account that is used for running `mariadbd` , or run it as `root` and use the `--user` option to indicate the username that `mariadbd` runs as. It might be necessary to specify other options such as `--basedir` or `--datadir` if `mariadb-install-db` does not use the correct locations for the installation directory or data directory. Here is a typical invocation:

```
$ scripts/mariadb-install-db --user=mysql \
   --basedir=/opt/mysql/mysql \
   --datadir=/opt/mysql/mysql/data
```

Options

`mariadb-install-db` supports the following options:

–auth-root-authentication-method={ `normal` | `socket` }

If set to `normal`, it creates a `root@localhost` account that authenticates with the `mysql_native_password` authentication plugin and that has no initial password set, which can be insecure. If set to `socket`, it creates a `root@localhost` account that authenticates with the `unix_socket` authentication plugin. Set to `socket` by default.

–auth-root-socket-user=*username*

Used with `--auth-root-authentication-method=socket`. It specifies the name of the second account to create with SUPER privileges in addition to root, as well as of the system account allowed to access it. Defaults to the value of `--user`.

–basedir=*path*

The *path* to the MariaDB installation directory.

–builddir=*directory*

If using `--srcdir` with out-of-directory builds, you will need to set this to the location of the *build directory* where built files reside.

–catalogs=["*list*"]

Initialize MariaDB for catalogs. Argument is a *list of the catalogs to create*, separated with space or comma. The def catalog is created automatically. This option is available from MariaDB 11.7.

–catalog-user=*username*

User when adding catalogs to running server. This option is available from MariaDB 11.7.

–catalog-password[=*password*]

Password for catalog-user. This option is available from MariaDB 11.7.

–catalog-client-arg=*argument*

Other *arguments* to `mariadb` when adding new catalogs. This option is available from MariaDB 11.7.

–cross-bootstrap

For internal use. Used when building the MariaDB system tables on a different host than the target.

–datadir=*path*, –ldata=*path*

The *path* to the MariaDB data directory.

–client-debug

Write commands to-be executed in `/tmp/mariadb_install_db.log`. This option is available from MariaDB 11.6.

–server-debug

Start mariadbd (server) with `--debug`.

–defaults-extra-file=*file*

Read this *file* after the global files are read. Must be given as the first option.

–defaults-file=*file*

Only read default options from the given *file* name. Must be given as the first option.

–defaults-group-suffix=*suffix*

In addition to the given groups, read also groups with this *suffix*.

–force

Causes mariadb-install-db to run even if DNS does not work. In that case, grant table entries that normally use host names will use IP addresses.

–no-defaults

Don't read default options from any option file. Must be given as the first option.

–print-defaults

Print the program argument list and exit. Must be given as the first option.

–rpm

For internal use. This option is used by RPM files during the MariaDB installation process.

–skip-name-resolve

Uses IP addresses rather than host names when creating grant table entries. This option can be useful if your DNS does not work.

–skip-test-db

Don't install the test database.

–srcdir=*path*

For internal use. The *path* to the MariaDB source directory. This option uses the compiled binaries and support files within the source tree, useful for if you don't want to install MariaDB yet and just want to create the system tables. The directory under which mariadb-install-db looks for support files such as the error message file and the file for populating the help tables.

–user=*username*

The login *username* to use for running mariadbd. Files and directories created by mariadbd is owned by this user. You must be root to use this option. By default, mariadbd runs using your current login name and files and directories that it creates is owned by you.

–verbose

Verbose mode. Print more information about what the program does.

–windows

For internal use. This option is used for creating Windows distributions.

Option Files

In addition to reading options from the command line, `mariadb-install-db` can also read options from option files. If an unknown option is provided to `mariadb-install-db` in an option file, then it is ignored.

The following options relate to how MariaDB command line tools handles option files. They must be given as the first argument on the command line:

Option	Description
–print-defaults	Print the program argument list and exit.
–no-defaults	Don't read default options from any option file.
–defaults-file=#	Only read default options from the given file #.
–defaults-extra-file=#	Read this file after the global files are read.
–defaults-group-suffix=#	In addition to the default option groups, also read option groups with this suffix.

Option Groups

`mariadb-install-db` reads options from the following option groups from option files:

Group	Description
[mysql_install_db]	Options read by mysqld_safe, which includes both MariaDB Server and MySQL Server.

`mariadb-install-db` also reads options from the following server option groups from option files:

Group	Description
[mysqld]	Options read by mysqld, which includes both MariaDB Server and MySQL Server.
[server]	Options read by MariaDB Server.
[mysqld-X.Y]	Options read by a specific version of mysqld, which includes both MariaDB Server and MySQL Server. For example, [mysqld-5.5].
[mariadb]	Options read by MariaDB Server.
[mariadb-X.Y]	Options read by a specific version of MariaDB Server.
[client-server]	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients.
[galera]	Options read by a galera-capable MariaDB Server. Available on systems compiled with Galera support.

Installing System Tables

Installing System Tables From a Source Tree

If you have just compiled MariaDB from source, and if you want to use `mariadb-install-db` from your source tree, then that can be done without having to actually install MariaDB. This is very useful if you want to test your changes to MariaDB without disturbing any existing installations of MariaDB.

To do so, you would have to provide the `--srcdir` option. For example:

```
./scripts/mariadb-install-db --srcdir=. --datadir=path-to-temporary-data-dir
```

Installing System Tables From a Binary Tarball

If you install a binary tarball package in a non standard path, like your home directory, and if you already have a MariaDB / MySQL package installed, then you may get conflicts with the default `/etc/my.cnf`. This often results in permissions errors.

One possible solution is to use the `--no-defaults` option, so that it does not read any option files. For example:

```
./scripts/mariadb-install-db --no-defaults --basedir=. --datadir=data
```

Another possible solution is to use the `defaults-file` option, so that you can specify your own option file. For example:

```
./scripts/mariadb-install-db --defaults-file=~/.my.cnf
```

User Accounts Created by Default

`mariadb-install-db` sets `--auth-root-authentication-method=socket` by default. When this is set, the default `root@localhost` user account is created with the ability to use two authentication plugins:

- First, it is configured to try to use the unix_socket authentication plugin. This allows the `root@localhost` user to login without a password via the local Unix socket file defined by the socket system variable, as long as the login is attempted from a process owned by the operating system `root` user account.
- Second, if authentication fails with the unix_socket authentication plugin, then it is configured to try to use the mysql_native_password authentication plugin.

The definition of the default `root@localhost` user account is:

```
CREATE USER 'root'@'localhost' IDENTIFIED VIA unix_socket
  OR mysql_native_password USING 'invalid';
GRANT ALL PRIVILEGES ON *.* TO 'root'@'localhost' WITH GRANT OPTION;
GRANT PROXY ON ''@'%' TO 'root'@'localhost' WITH GRANT OPTION;
```

Since `mariadb-install-db` sets `--auth-root-authentication-method=socket` by default, the following additional user accounts are **not** created by default:

- `root@127.0.0.1`
- `root@::1`
- `root@${current_hostname}`

However, an additional user account that is defined by the `--auth-root-socket-user` option is created. If this option is not set, then the value defaults to the value of the `--user` option. On most systems, the `--user` option will use the value of `mysql` by default, so this additional user account would be called `mysql@localhost`.

The definition of this `mysql@localhost` user account is similar to the `root@localhost` user account:

```
CREATE USER 'mysql'@'localhost' IDENTIFIED VIA unix_socket
  OR mysql_native_password USING 'invalid';
GRANT ALL PRIVILEGES ON *.* TO 'mysql'@'localhost' WITH GRANT OPTION;
```

An invalid password is initially set for both of these user accounts. This means that before a password can be used to authenticate as either of these user accounts, the accounts must first be given a valid password by executing the SET PASSWORD statement.

For example, here is an example of setting the password for the `root@localhost` user account immediately after installation:

```
$ sudo yum install MariaDB-server
$ sudo systemctl start mariadb
$ sudo mariadb
...
MariaDB> SET PASSWORD = PASSWORD('XH4VmT3_jt');
```

You may notice in the above example that the mariadb command-line client is executed via sudo. This allows the `root@localhost` user account to successfully authenticate via the unix_socket authentication plugin.

Troubleshooting Issues

Checking the Error Log

If `mariadb-install-db` fails, you should examine the error log in the data directory, which is the directory specified with `--datadir` option. This should provide a clue about what went wrong.

Testing With mariadbd

You can also test that this is not a general fault of MariaDB Server by trying to start the `mariadbd` process. The `--skip-grant-tables` option will tell it to ignore the system tables. Enabling the general query log can help you determine what queries are being run on the server. For example:

```
mariadbd --skip-grant-tables --general-log
```

At this point, you can use the mariadb client to connect to the mysql database and look at the system tables. For example:

```
$ /usr/local/mysql/bin/mysql -u root mysql
MariaDB [mysql]> show tables
```

Using a Server Compiled With –disable-grant-options

The following only apply in the exceptional case that you are using a mariadbd server which is configured with the `--disable-grant-options` option:

`mariadb-install-db` needs to invoke `mariadbd` with the `--bootstrap` and `--skip-grant-tables` options.
A MariaDB configured with the `--disable-grant-options` option has `--bootstrap` and `--skip-grant-tables` disabled. To handle this case, set the `MYSQLD_BOOTSTRAP` environment variable to the full path name of a mariadbd server that is configured without `--disable-grant-options`. `mariadb-install-db` will use that server.

The test and test_% Databases

When calling the `mariadb-install-db` script, a new folder called `test` is created in the data directory.
It only has the single `db.opt` file, which sets the client options `default-character-set` and `default-collation` only.

If you run `mysql` as an anonymous user, `mysql -u''@localhost`, and look for the grants and databases you are able to work with, you will get the following:

```
SELECT current_user;
+--------------+
| current_user |
+--------------+
| @localhost   |
+--------------+

SHOW GRANTS FOR current_user;
+---------------------------------------+
| Grants for @localhost                 |
+---------------------------------------+
| GRANT USAGE ON *.* TO ``@`localhost` |
+---------------------------------------+

SHOW DATABASES;
+--------------------+
| Database           |
+--------------------+
| information_schema |
| test               |
+--------------------+
```

Shown are the `information_schema` as well as `test` databases that are built in databases.
But looking from SHOW GRANTS appears to be a paradox; how can the current user see something if they don't have privileges for that?

Let's go a step further.
Now, use the `root` / `unix` user, which has all rights, in order to create a new database with the prefix `test_` , something like:

```
CREATE DATABASE test_electricity;
```

With the above change, a new directory is created in the data directory.
Now login again with the anonymous user and run SHOW DATABASES:

```
SHOW DATABASES
+--------------------+
| Database           |
+--------------------+
| information_schema |
| test               |
| test_electricity   |
+--------------------+
```

Again we are able to see the newly created database, without any rights?
We have an anonymous user that has no privileges, but still can see the `test` and `test_electricity` databases.
Where does this come from?

Log in with the `root` / `unix` user to find out all privileges that the anonymous user has:

```
SELECT * FROM mysql.user WHERE user='' AND host='localhost'\G
*************************** 1. row ***************************
                 Host: localhost
                 User:
             Password:
           Select_priv: N
           Insert_priv: N
           Update_priv: N
           Delete_priv: N
           Create_priv: N
             Drop_priv: N
           Reload_priv: N
         Shutdown_priv: N
          Process_priv: N
             File_priv: N
            Grant_priv: N
       References_priv: N
            Index_priv: N
            Alter_priv: N
          Show_db_priv: N
            Super_priv: N
 Create_tmp_table_priv: N
      Lock_tables_priv: N
          Execute_priv: N
       Repl_slave_priv: N
      Repl_client_priv: N
      Create_view_priv: N
        Show_view_priv: N
   Create_routine_priv: N
    Alter_routine_priv: N
      Create_user_priv: N
            Event_priv: N
          Trigger_priv: N
Create_tablespace_priv: N
   Delete_history_priv: N
              ssl_type:
            ssl_cipher:
           x509_issuer:
          x509_subject:
         max_questions: 0
           max_updates: 0
       max_connections: 0
  max_user_connections: 0
                plugin:
 authentication_string:
      password_expired: N
               is_role: N
          default_role:
    max_statement_time: 0.000000
```

As seen above from the mysql.user table, the anonymous user doesn't have any global privileges.
Still, the anonymous user can see databases, so there must be a way so that anonymous user can see the `test` and `test_electricity` databases.

Let's check for grants on the database level. That information can be found in the mysql.db table.
Looking at the `mysql.db` table, it already contains 2 rows created when the `mariadb-install-db` script was invoked.

The anonymous user has database privileges (without `grant`, `alter_routine` and `execute`) on `test` and `test_%` databases:

```
SELECT * FROM mysql.db\G
*************************** 1. row ***************************

```

The first row is reserved for explicit usage for the `test` database, which is automatically created with `mariadb-install-db`.

Since database `test_electricity` satisfies the `test_%` pattern where `test_` is a prefix, we can understand why the user has the right to work with the newly-created database.

As long as records in `mysql.db` for the anonymous user exists, each new user created will have the privileges for the `test` and `test_%` databases.

Other databases privileges **are not automatically granted** for the newly created user. We have to grant privileges, which is visible in `mysql.db` table.

Not Creating the test Database and Anonymous User

If you run `mariadb-install-db` with the `--skip-test-db` option, no `test` database is created, which we can see as follows:

```
SHOW DATABASES;
+--------------------+
| Database           |
+--------------------+
| information_schema |
| mysql              |
| performance_schema |
+--------------------+

SELECT * FROM mysql.db;
Empty set (0.001 sec)
```

Also, no anonymous user is created (only `unix` / `mariadb.sys` / `root` users):

```
SELECT user,host FROM mysql.user;
+-------------+-----------+
| User        | Host      |
+-------------+-----------+
| anel        | localhost |
| mariadb.sys | localhost |
| root        | localhost |
+-------------+-----------+
```

mariadb-upgrade

`mariadb-upgrade` is a tool that checks and updates your tables to the latest version.

> **Note:**
>
> Previously, the client was called `mysql_upgrade` . It can still be accessed under this name, via a symlink in Linux, or an alternate binary in Windows.

Overview

You should run `mariadb-upgrade` after upgrading from one major MariaDB release to another, such as from MariaDB 10.11 to MariaDB 11.4. You also have to use `mariadb-upgrade` after migrating to MariaDB from MySQL. It's also safe to run `mariadb-upgrade` for minor upgrades, as, if there are no incompatibilities, nothing is changed.

> **CURRENT**
>
> `mariadb-upgrade` needs to be run as a user with write access to the data directory.
>
> Starting from mariadb-upgrade 2.0, the user running the upgrade tool must have write access to `datadir/mysql_upgrade_info` , so that the tool can write the current MariaDB version into the file.
>
> **< 10.7.2 / 10.6.6 / 10.5.14**

> `mariadb-upgrade` needs to be run as a user with write access to the data directory.

`mariadb-upgrade` is run after starting the new MariaDB server. Running it before you shut down the old version will not hurt anything and will allow you to make sure it works and figure out authentication for it ahead of time.

> **Note:**
>
> The MariaDB server never performs the upgrade itself. On startup, if it detects an out-of-date system table or a version mismatch, it only writes a message to the error log recommending that you run `mariadb-upgrade`.
>
> On Debian and Ubuntu, the server packages run `mariadb-upgrade` for you automatically after a package upgrade: once the new server has started, the startup script runs it in the background, using `--version-check` so the work is only done once per major version. On RPM-based distributions, and whenever you start the server directly (for example with `systemd` or by running `mariadbd`), `mariadb-upgrade` is not run automatically and you must run it yourself.

> **Tip:**
>
> It is recommended to make a backup of all databases before running `mariadb-upgrade`.

In most cases, `mariadb-upgrade` should just take a few seconds. The main work of `mariadb-upgrade` is to:

- Update the system tables in the `mysql` database to the latest version (normally just add new fields to a few tables).
- Check that all tables are up to date (runs CHECK TABLE table_name FOR UPGRADE). For tables that are not up to date, runs ALTER TABLE table_name FORCE on the table to update it. A table is not up to date in the following cases:
  - The table uses an index for which there has been a collation change (rare).
  - A format change in the storage engine requires an update (very rare).

Why run mariadb-upgrade?

If you skip running `mariadb-upgrade`, issues can arise, including these:

- Errors in the error log that some system tables don't have all needed columns.
- Updates or searches may not find the record they are attempting to update or search for.
- CHECKSUM TABLE may report the wrong checksum for MyISAM or Aria tables.
- The error message "Cannot load from mysql.proc. The table is probably corrupted."

To fix issues like this, run `mariadb-upgrade`, mariadb-check, CHECK TABLE and, if needed, REPAIR TABLE on the faulty table.

Upgrading to a Minor Version, or to Enterprise Server

Starting from mariadb-upgrade 2.0, mysql-upgrade doesn't run when upgrading to a new minor version (for instance, from MariaDB 10.6.3 to 10.6.4).

> **Warning:**
>
> This includes updating from Community Server to Enterprise Server.

In those cases, mariadb-upgrade terminates with a message like this:

```
This installation of MariaDB is already upgraded to 10.11.4-MariaDB.
There is no need to run mysql_upgrade again for 10.11.11-MariaDB.
You can use --force if you still want to run mysql_upgrade.
```

As the message indicates, use the –force option to override this behavior.

> **Warning:**
>
> When upgrading from, say, Community Server 10.11.4 to Enterprise Server 10.11.11, mariadb-upgrade considers that a minor-version upgrade, so you must use the `--force` option to make it run.

Usage

```
mariadb-upgrade [--force] [--user=# --password=#
  --host=hostname --port=# --socket=#
  --protocol=tcp|socket|pipe|memory
  --verbose] [OTHER_OPTIONS]
```

`mariadb-upgrade` is mainly a framework to call mariadb-check. `mariadb-upgrade` works by doing the following operations:

```
# Find out path to datadir
echo "show variables like 'datadir'" | mysql
mariadb-check --no-defaults --check-upgrade --auto-repair --databases mysql
mysql_fix_privilege_tables
mariadb-check --no-defaults --all-databases --fix-db-names --fix-table-names
mariadb-check --no-defaults --check-upgrade --all-databases --auto-repair
```

The connect options given to `mariadb-upgrade` are passed along to mariadb-check and mariadb command-line client.

The `mysql_fix_privilege_tables` script is not called; it's included as part of `mariadb-upgrade` .

If you have a problem with `mariadb-upgrade` , try running it in very verbose mode:

```
mariadb-upgrade --verbose --verbose other-options
```

`mariadb-upgrade` also saves the MariaDB version number in a file named `mysql_upgrade_info` in the data directory. This is used to quickly check whether all tables have been checked for this release so that table-checking can be skipped. For this reason, `mariadb-upgrade` needs to be run as a user with write access to the data directory. To ignore this file and perform the check regardless, use the `--force` option.

> **Warning:**
>
> Because this check relies on the version recorded in `mysql_upgrade_info` , restoring a `mariadb-dump` (`mysqldump`) backup taken from an older server version can leave the restored system tables out of date while the file still shows the current version. In that case, `mariadb-upgrade` reports that no upgrade is needed, so run it with the `--force` option to upgrade the restored tables.

Options

`mariadb-upgrade` supports the following options:

-?, –help

Display this help message and exit.

–basedir=*path*

Old option accepted for backward compatibility but ignored.

–character-sets-dir=*path*

Old option accepted for backward compatibility but ignored.

–check-if-upgrade-is-needed

Do a quick check if upgrade is needed. Returns `0` if an upgrade is needed, `1` if not. Available from mariadb-upgrade 2.0.

–compress=*name*

Old option accepted for backward compatibility but ignored.

–datadir=*name*

Old option accepted for backward compatibility but ignored.

–debug-check

Check memory and open file usage at exit.

-T, –debug-info

Print some debug info at exit.

–default-character-set=*name*

Old option accepted for backward compatibility but ignored.

-f, –force

Force execution of mariadb-check even if mariadb-upgrade has already been executed for the current version of MariaDB. Ignores `mysql_upgrade_info`.

-h, –host=*host*

Connect to MariaDB on the given *host*.

-p, –password=*password*

Password to use when connecting to server. If password is not given, it's solicited on the command line (which should be considered insecure). You can use an option file to avoid giving the password on the command line.

-P, –port=*port-number*

Port number to use for connection or 0 for default to, in order of preference, my.cnf, the `MYSQL_TCP_PORT` environment variable, `/etc/services`, built-in default (`3306`).

–protocol=*protocol*

The *protocol* to use for connection (`tcp`, `socket`, `pipe`, `memory`).

–silent

Print less information.

-S, –socket=*file*

For connections to localhost, the Unix socket *file* to use, or, on Windows, the name of the *named pipe* to use.

–ssl

Enables TLS. TLS is also enabled even without setting this option when certain other TLS options are set. The `--ssl` option does not enable verifying the server certificate by default. In order to verify the server certificate, you must specify the `--ssl-verify-server-cert` option.

–ssl-ca=*path*

Defines a *path* to a PEM file that should contain one or more X509 certificates for trusted Certificate Authorities (CAs) to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option implies the `--ssl` option.

–ssl-capath=*path*

Defines a *path* to a directory that contains one or more PEM files that should each contain one X509 certificate for a trusted Certificate Authority (CA) to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the openssl rehash command. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option is only supported if the client was built with OpenSSL or yaSSL. If the client was built with GnuTLS or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms. This option implies the `--ssl` option.

–ssl-cert=*path*

Defines a *path* to the X509 certificate file to use for TLS. This option requires that you use the absolute path, not a relative path. This option implies the `--ssl` option.

–ssl-cipher=*ciphers*

List of permitted ciphers or cipher suites to use for TLS. This option implies the `--ssl` option.

–ssl-crl=*path*

Defines a *path* to a PEM file that should contain one or more revoked X509 certificates to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL or Schannel. If the client was built with yaSSL or GnuTLS, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.

–ssl-crlpath=*path*

Defines a *path* to a directory that contains one or more PEM files that should each contain one revoked X509 certificate to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the openssl rehash command. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL. If the client was built with yaSSL, GnuTLS, or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.

–ssl-key=*file*

Defines a path to a *private key file* to use for TLS. This option requires that you use the absolute path, not a relative path. This option implies the `--ssl` option.

–ssl-verify-server-cert

Enables server certificate verification. This option is disabled by default.

-t, –tmpdir=*directory*

Directory for temporary files.

-s, –upgrade-system-tables

Only upgrade the system tables in the mysql database. Tables in other databases are not checked or touched.

-u, –user=name

User for login if not current user.

-v, –verbose

Display more output about the process, using it twice will print connection arguments; using it 3 times will print out all CHECK, RENAME and ALTER TABLE commands used during the check phase; using it 4 times will also write out all mariadb-check commands used.

-V, –version

Output version information and exit.

-k, –version-check

Run this program only if its 'server version' matches the version of the server to which it's connecting check. Note: the 'server version' of the program is the version of the MariaDB server with which it was built/distributed. (Defaults to on; use `--skip-version-check` to disable.)

–write-binlog

> **CURRENT**
>
> All commands, including those run by mariadb-check, are written to the binary log. Disabled by default.
>
> **< 10.0.6**
>
> All commands, including those run by mariadb-check, are written to the binary log. Enabled by default. The `--skip-write-binlog` option must be used when commands should not be sent to replication replicas.

Option Files

In addition to reading options from the command line, `mariadb-upgrade` can also read options from option files. If an unknown option is provided to `mariadb-upgrade` in an option file, then it is ignored.

The following options relate to how MariaDB command line tools handles option files. They must be given as the first argument on the command line:

Option	Description
–print-defaults	Print the program argument list and exit.
–no-defaults	Don't read default options from any option file.
–defaults-file=#	Only read default options from the given file #.
–defaults-extra-file=#	Read this file after the global files are read.
–defaults-group-suffix=#	In addition to the default option groups, also read option groups with this suffix.

`mariadb-upgrade` is linked with MariaDB Connector/C. However, MariaDB Connector/C does not handle the parsing of option files for `mariadb-upgrade`. That is still performed by the server option file parsing code. See MDEV-19035 for more information.

Option Groups

`mariadb-upgrade` reads options from the following option groups from option files:

Group	Description
[mysql_upgrade]	Options read by mariadb-upgrade, which includes both MariaDB Server and MySQL Server.
[mariadb-upgrade]	Options read by mariadb-upgrade. Available starting with MariaDB 10.4.6.
[client]	Options read by all MariaDB and MySQL client programs, which includes both MariaDB and MySQL clients. For example, mysqldump.
[client-server]	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients.
[client-mariadb]	Options read by all MariaDB client programs.

Differences Between mysql_upgrade in MariaDB and MySQL

- MariaDB converts long table names properly.
- MariaDB converts InnoDB tables (no need to do a dump/restore or ALTER TABLE).
- MariaDB converts old archive tables to the new 5.1 format.
- `mysql_upgrade --verbose` runs `mariadb-check --verbose`, so that you get more information of what is happening. Running with 3 times –verbose prints out all `CHECK`, `RENAME` and `ALTER TABLE` statements executed.
- The mysql.event table is upgraded live. There is no need to restart the server to use events if the event table has changed.
- More descriptive output.

Speeding up mariadb-upgrade

- If you are sure that all your tables are up to date with the current version, then you can run `mariadb-upgrade --upgrade-system-tables`, which will only fix your system tables in the mysql database to be compatible with the latest version.

The main reason to run `mariadb-upgrade` on all your tables is to allow it to check that:

- There has not been any change in table formats between versions.
- This has not happened since MariaDB 5.1.
- If some of the tables are using an index for which we have changed sort order.
- This has not happened since MariaDB 5.5.

> **Warning:**
>
> If you are sure this applies to your situation, you can just run `mariadb-upgrade` with the `--upgrade-system-tables` option.

Other Uses

- `mariadb-upgrade` recreates any missing tables in the mysql database. It doesn't touch any data in existing tables.

mariadb-upgrade 2.0

> **Note:**
>
> `mariadb-upgrate/mysql_upgrade 2.0` was introduced in MariaDB 10.5.14 / 10.6.6 / 10.7.2.

Previously, the tool first ran the upgrade process and then created the `datadir/mysql_upgrade_info` file. If the file could not be created because of permissions (`mariadb-upgrade` did not have rights to create the file), `mariadb-upgrad` gave an error, but this was often ignored. One effect of not being able to create the `mysql_upgrade_info` file was that every new `mariadb-upgrade` run would have to do a full upgrade check, which can take a while if there are a lot of tables.

`mariadb-upgrade` 2.0 fixes the following issues:

- The `datadir/mysql_upgrade_info` is now created at the start of the upgrade process and locked. This ensures that two `mariadb-upgrade` processes cannot be run in parallel, which can cause deadlocks (MDEV-27068). One side effect of this is that `mariadb-upgrade` has to have write access to `datadir`, which means it has to be run as the user that installed MariaDB, normally 'mysql' or 'root' .
- One can use `mariadb-upgrade --force --force` to force the upgrade to be run, even if there was no version change or if one doesn't have write access to `datadir`. Note that if this option is used, the next `mariadb-upgrade` run will assume that there is a major version change and the upgrade must be done (again).
- The upgrade is done only if there is a major server version change (for instance, from MariaDB 10.5 to 10.6). This avoids unnecessary upgrades.
- New option added: `--check-if-upgrade-is-needed`. If this is used, `mariadb-upgrade` will return `0` if there has been a major version change and you should run `mariadb-upgrade`. If not upgrade is needed, `1` is returned.
- `--verbose` writes more information, including from which version to which version the upgrade is done.
- Better messages when there is no need to run `mariadb-upgrade`.

mariadb-secure-installation

> **Note:**
>
> Note that many of the reasons for the existence of this script no longer apply (and therefore the guidelines in many online tutorials. In particular, from MariaDB 10.4, Unix socket authentication is applied by default, and there is usually no need to create a root password. See Authentication from MariaDB 10.4.

> **Note:**
>
> Previously, the client was called `mysql_secure_installation`. It can still be accessed under this name, via a symlink in Linux, or an alternate binary in Windows.

Description

`mariadb-secure-installation` is a shell script available on Unix systems, and enables you to improve the security of your MariaDB installation in the following ways:

- You can set a password for root accounts.
- You can remove root accounts that are accessible from outside the local host.
- You can remove anonymous-user accounts.

- You can remove the test database, which by default can be accessed by anonymous users.

`mariadb-secure-installation` can be invoked without arguments:

```
shell> mariadb-secure-installation
```

The script will prompt you to determine which actions to perform.

```
Example:
localhost:# mariadb-secure-installation
NOTE: RUNNING ALL PARTS OF THIS SCRIPT IS RECOMMENDED FOR ALL MariaDB
      SERVERS IN PRODUCTION USE!  PLEASE READ EACH STEP CAREFULLY!
In order to log into MariaDB to secure it, we'll need the current
password for the root user.  If you've just installed MariaDB, and
you haven't set the root password yet, the password is blank,
so you should just press enter here.
Enter current password for root (enter for none):
OK, successfully used password, moving on...
Setting the root password ensures that nobody can log into the MariaDB
root user without the proper authorisation.
You already have a root password set, so you can safely answer 'n'.
Change the root password? [Y/n] n
 ... skipping.
By default, a MariaDB installation has an anonymous user, allowing anyone
to log into MariaDB without having to have a user account created for
them.  This is intended only for testing, and to make the installation
go a bit smoother.  You should remove them before moving into a
production environment.
Remove anonymous users? [Y/n] y
 ... Success!
Normally, root should only be allowed to connect from 'localhost'.  This
ensures that someone cannot guess at the root password from the network.
Disallow root login remotely? [Y/n] y
 ... Success!
By default, MariaDB comes with a database named 'test' that anyone can
access.  This is also intended only for testing, and should be removed
before moving into a production environment.
Remove test database and access to it? [Y/n] y
 - Dropping test database...
 ... Success!
 - Removing privileges on test database...
 ... Success!
Reloading the privilege tables will ensure that all changes made so far
will take effect immediately.
Reload privilege tables now? [Y/n] y
 ... Success!
Cleaning up...
All done!  If you've completed all of the above steps, your MariaDB
installation should now be secure.
Thanks for using MariaDB!
```

Options

`mariadb-secure-installation` accepts some options:

Option	Description
–basedir=dir	Base directory.
–no-defaults	Don’t read default options from any option file.
–defaults-file=#	Only read default options from the given file #.
–defaults-extra-file=#	Read this file after the global files are read.

Other unrecognized options is passed on to the server.

Option Files

In addition to reading options from the command line, `mariadb-secure-installation` can also read options from option files. If an unknown option is provided to `mariadb-secure-installation` in an option file, it is ignored.

The following options relate to how MariaDB command-line tools handle option files. They must be given as the first argument on the command line:

Option	Description
–no-defaults	Don't read default options from any option file.
–defaults-file=#	Only read default options from the given file #.
–defaults-extra-file=#	Read this file after the global files are read.
–defaults-group-suffix=#	In addition to the default option groups, also read option groups with this suffix.

Option Groups

`mariadb-secure-installation` reads options from the following option groups from option files:

Group	Description
[client]	Options read by all MariaDB and MySQL client programs, which includes both MariaDB and MySQL clients like mysqldump.
[client-server]	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients.
[client-mariadb]	Options read by all MariaDB client programs.

Use With Galera Cluster

> **Warning:**
>
> This script is not completely safe for use with Galera Cluster as it directly manipulates the mysql.user/mysql.global_priv table, which is not propagated by Galera to the other nodes.

You should run this script on the first node in the cluster before adding more nodes.

If you want to run this after the cluster is up and running, you should find alternative ways.

Anyone can vote for this to be fixed at MDEV-10112.

Adminer

> **Note:**
>
> Adminer is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

Adminer is a database administration web interface. It is usable via a web browser. It is written in PHP and requires a web server.

Adminer mainly supports MySQL, but it also supports MariaDB and other database management systems. Adminer has a wide range of plugins, some of which have been developed by the community.

Adminer is distributed with a dual license: Apache License 2.0 and GPL 2. Adminer does not have a commercial edition, but it accepts donations.

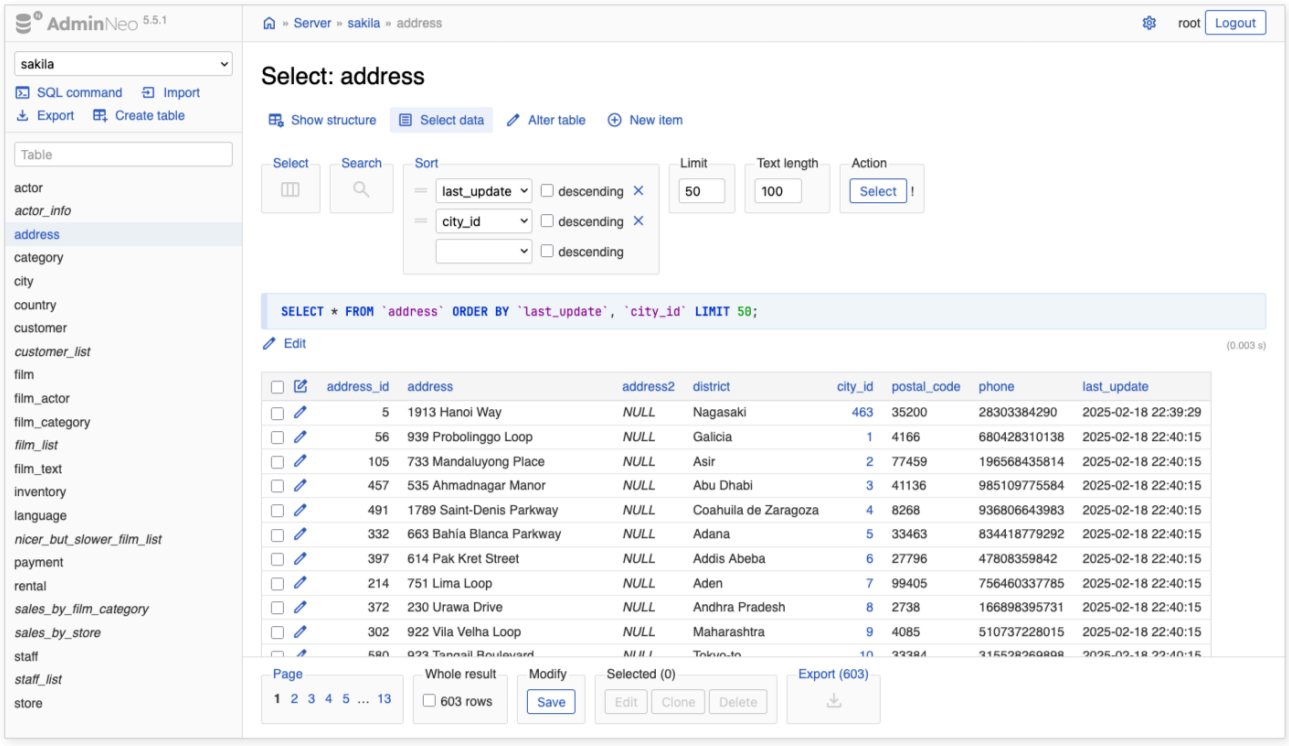
This page is licensed: CC BY-SA / Gnu FDL

AdminNeo

> **Note:**
>
> AdminNeo is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

AdminNeo is a database management tool written in PHP and used through a web browser. It consists of a single file that you deploy to a web server with PHP.

AdminNeo is based on the Adminer project, with a redesigned user interface and a refactored code base.



AdminNeo — selecting data

Key features

- Clean, modern user interface.

- Managing the structure of databases and tables.
- Data manipulation and searching.
- Exporting and importing databases and data.
- Executing batch SQL commands.
- Extensibility through plugins and customizations.

Supported databases

AdminNeo supports MariaDB through the MySQL driver. Other database systems: PostgreSQL, MS SQL, SQLite, Oracle, MongoDB, SimpleDB, Elasticsearch (beta) and ClickHouse (alpha).

License

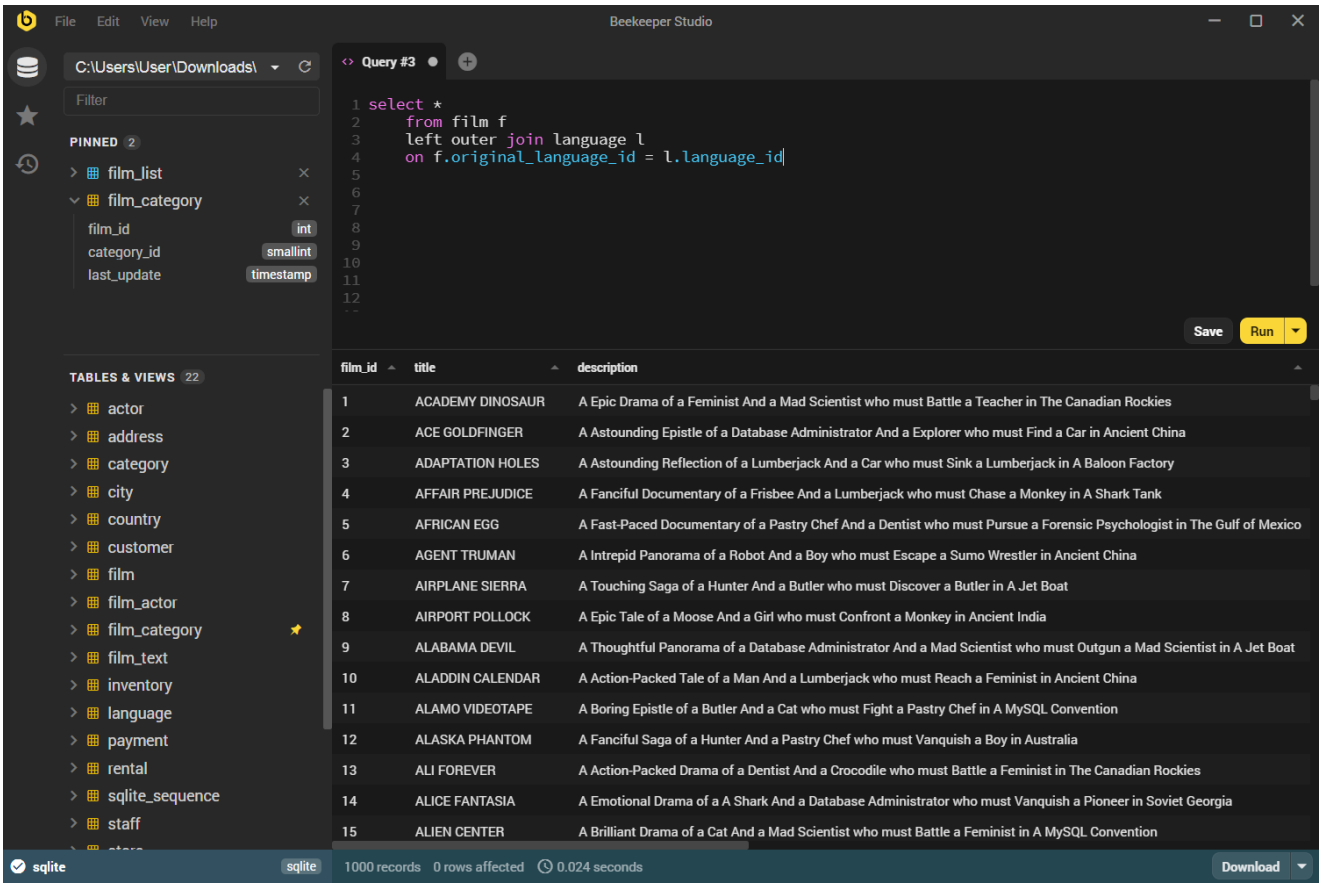
AdminNeo is dual-licensed under the Apache License 2.0 and GPL 2.

This page is licensed: CC BY-SA / Gnu FDL

Beekeeper Studio

> **Note:**
>
> Beekeeper Studio is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

Beekeeper Studio is an open-source database GUI available for Linux, MacOS, and Windows.



SQL Gui Screenshot

Beekeeper Studio works with MariaDB, but also works with other databases.

Beekeeper Studio includes the following features:

- Tabbed interface.
- SSH tunneling.
- SQL autocomplete.
- Multi-connection.

The Community Edition is free and open source, and is privacy respecting, with no usage tracking or similar behavior.

SQL Diagnostic Manager & SQLyog

> **Note:**
>
> SQL Diagnostic Manager and SQLyog are third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support them. Refer to their own documentation and license terms.

SQL Diagnostic Manager is a monitoring tool that gives database administrators real-time insights for optimizing the performance of MariaDB servers.

Key Features:

1. Agentless monitoring.
2. Fully customizable.
3. Affordable.

Webyog's SQL DM is fully compatible with Amazon Aurora databases, and Webyog is an Amazon launch partner.

Features specifically for RDS and Aurora instances also available. SQL Diagnostic Manager is browser based and is a proud MariaDB Monitor and Advisor.

SQLyog Ultimate is a MySQL administration tool for DBAs, developers, and database architects.
This tool enables database developers, administrators, and architects to visually compare, optimize, and document schemas.

Key Features:

1. Automatically synchronize data.
2. Visually compare data.
3. Import external data.

SQLyog runs on Windows and is a graphical MariaDB manager and admin tool, combining the features of MySQL Administrator, phpMyAdmin and other MariaDB frontend tools.

Database Workbench

> **Note:**
>
> Database Workbench is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

Database Workbench is a Windows application (*which works fine under Wine on Linux*) for database design, development, maintenance and testing for several database systems, including MySQL and MariaDB.

With Database Workbench you can:

- design a database;
- connect to multiple databases;
- view and modify meta data;
- view and modify data;
- import and export data;
- connect to any ODBC/ADO data source;
- transfer data between database systems;
- migrate meta data;
- compare meta data;
- manage privileges;
- debug stored procedure;
- print meta data or data.

It includes numerous other tools.

Database Workbench comes in multiple editions and is licensed on a per-module basis.

dbForge Data Compare

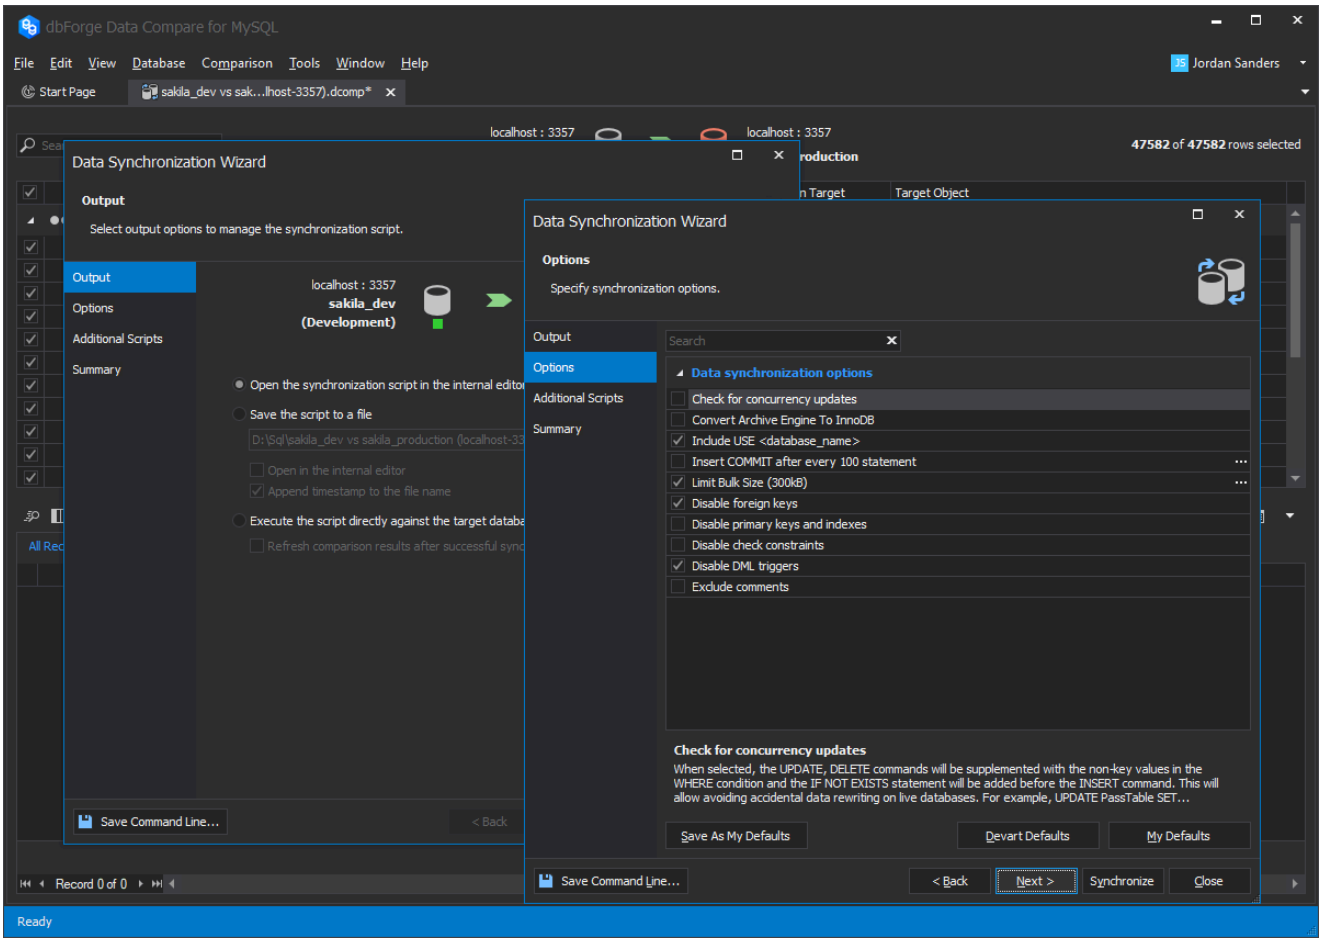
> **Note:**
>
> dbForge Data Compare is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

dbForge Data Compare helps compare and synchronize data in MariaDB, MySQL, and Percona databases and scripts folders. You can find differences between your data, as it helps analyze comparison results, creates a synchronization script, and applies changes. Additionally, MariaDB data can be compared with command-line support.

Features are described in the following.

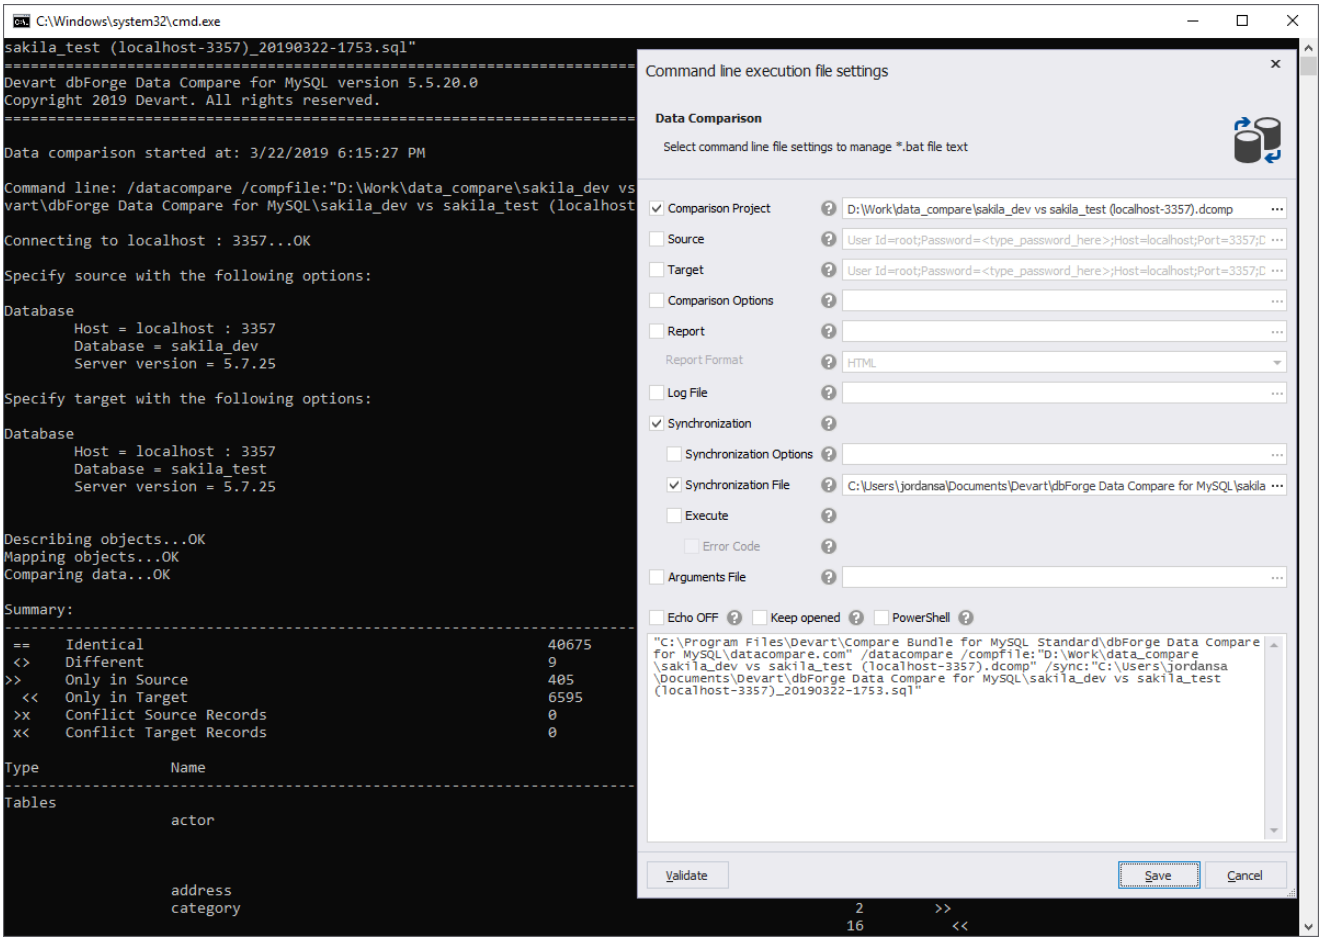
Database Synchronization Features

- Create accurate synchronization scripts.
- Synchronize asynchronous data.
- Create custom scripts with execution before/after the process of data synchronization.
- Get warning messages on errors during synchronization.



MySQL & MariaDB Task Automation

- Automate routine synchronizations with a command line interface.
- Plan routine execution with Windows Scheduler.
- Support for PowerShell compatibility.

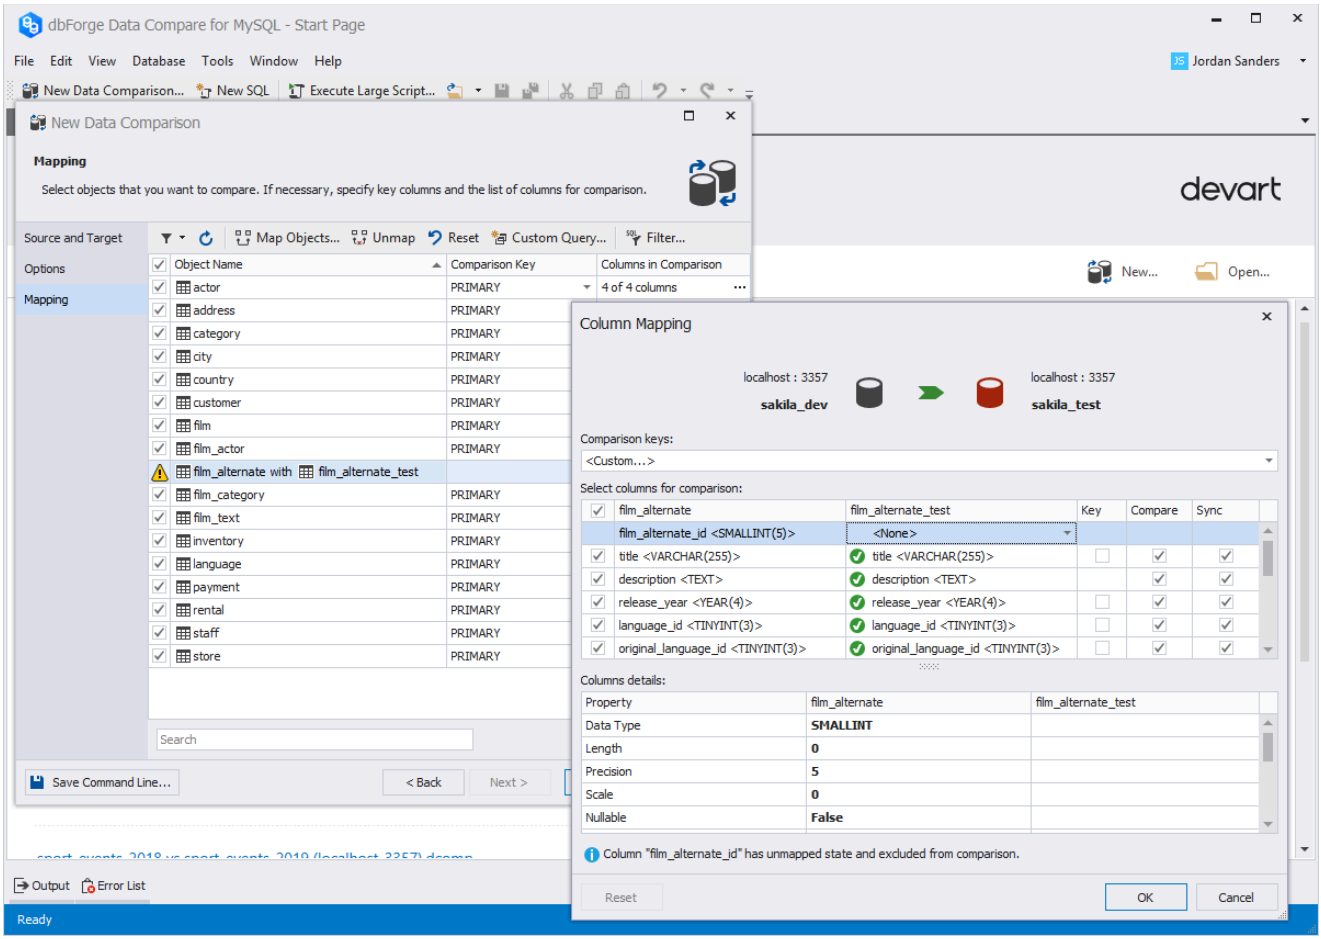


Script for Folder Data Comparison

- Compare data from your database with the data placed in the script folder locally.
- Choose any database, connection, or script folder with the new Data Comparison Wizard.
- See the data comparison results in a data result grid.

Configurations for Data Comparison

- Various options for automatic mapping.
- Compare customized queries.
- Compare custom keys.



Supported Data

- Tables.
- Temporal tables.
- Views.
- `BLOB` data.
- Compare databases and sync different MariaDB versions.

Compatibility Options

- All popular MariaDB server versions.
- MariaDB setup on Windows, Linux, FreeBSD, etc.
- Various cloud services: Amazon RDS, Amazon Aurora, Google Cloud, Oracle MySQL Cloud, Alibaba Cloud.
- Secure Socket Layer (SSL), Secure Shell (SSH), HTTP Tunneling, PAM Percona security connections.

Manage Comparison Results

- Find tables by name.
- Filter the comparison process results.
- Enter the values of default comparison options.
- Group records by type in each compared object.

Export Comparison Results

- Use only relevant data in your reports.
- Generate comparison reports in various formats.

Download a free 30-day trial of dbForge Data Compare here.

Documentation

Version	Introduced
dbForge Data Compare 10.1	Support for the rds-ca-rsa2048-g1 SSL/TLS certificate for connecting to MariaDB servers on AWS and enhanced cloud compatibility features, new automation capabilities.
dbForge Data Compare 10.0	Support for MariaDB 11.4, Added support for temporal tables in MariaDB.
dbForge Data Compare 5.9	Support for MariaDB 11.3.
dbForge Data Compare 5.8	Support for MariaDB 10.9 and 10.10.
dbForge Data Compare 5.7	Connectivity support for MariaDB 10.5.

dbForge Data Generator

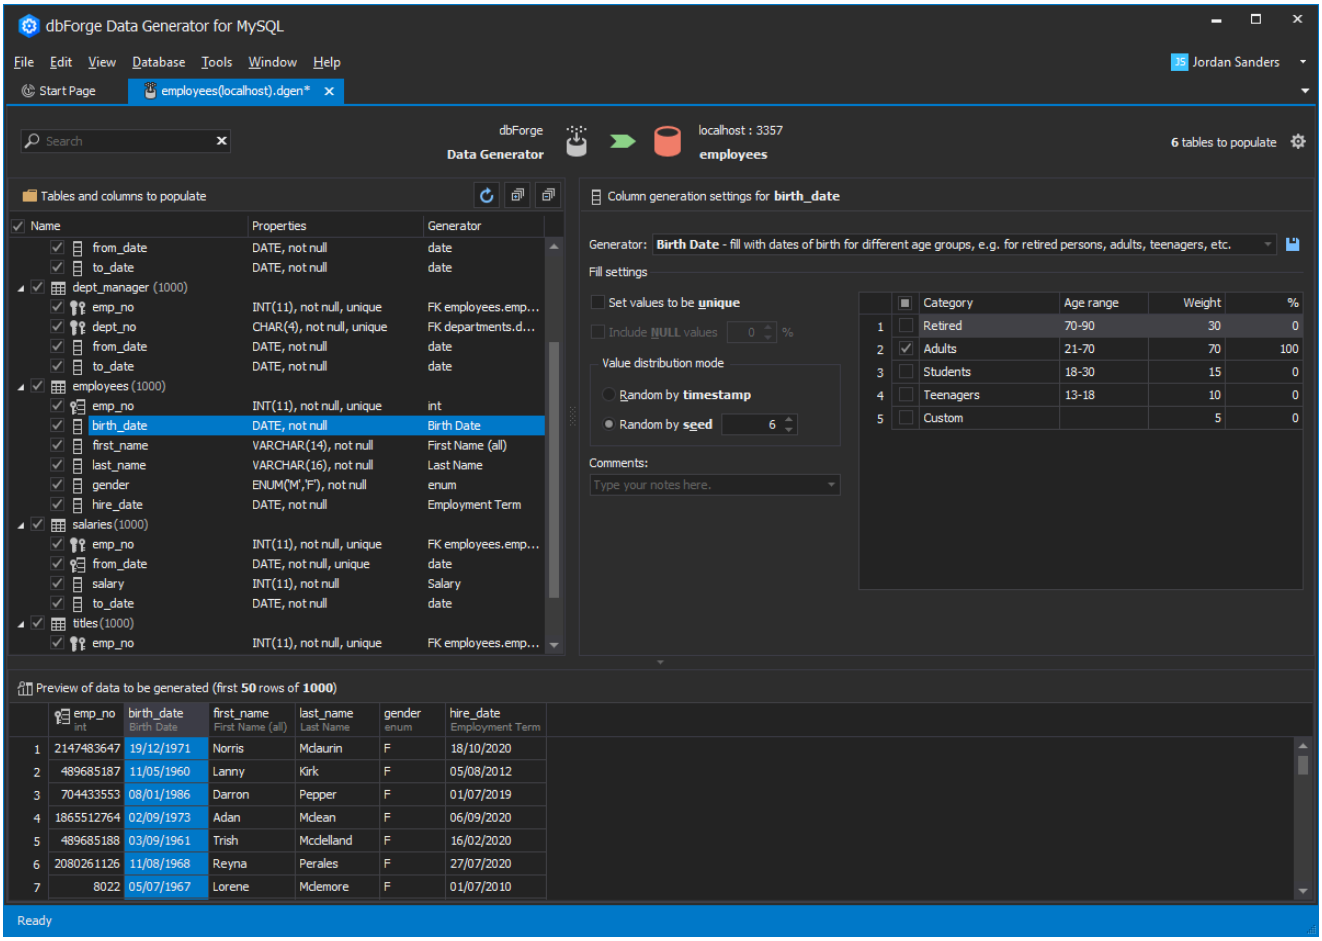
> **Note:**
>
> dbForge Data Generator is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

dbForge Data Generator for MariaDB and MySQL is a powerful solution that helps create massive volumes of meaningful and realistic data. This tool performs various predefined data generators with customizable options.

Data Generator Key Features:

1. Extensive support for all column data types

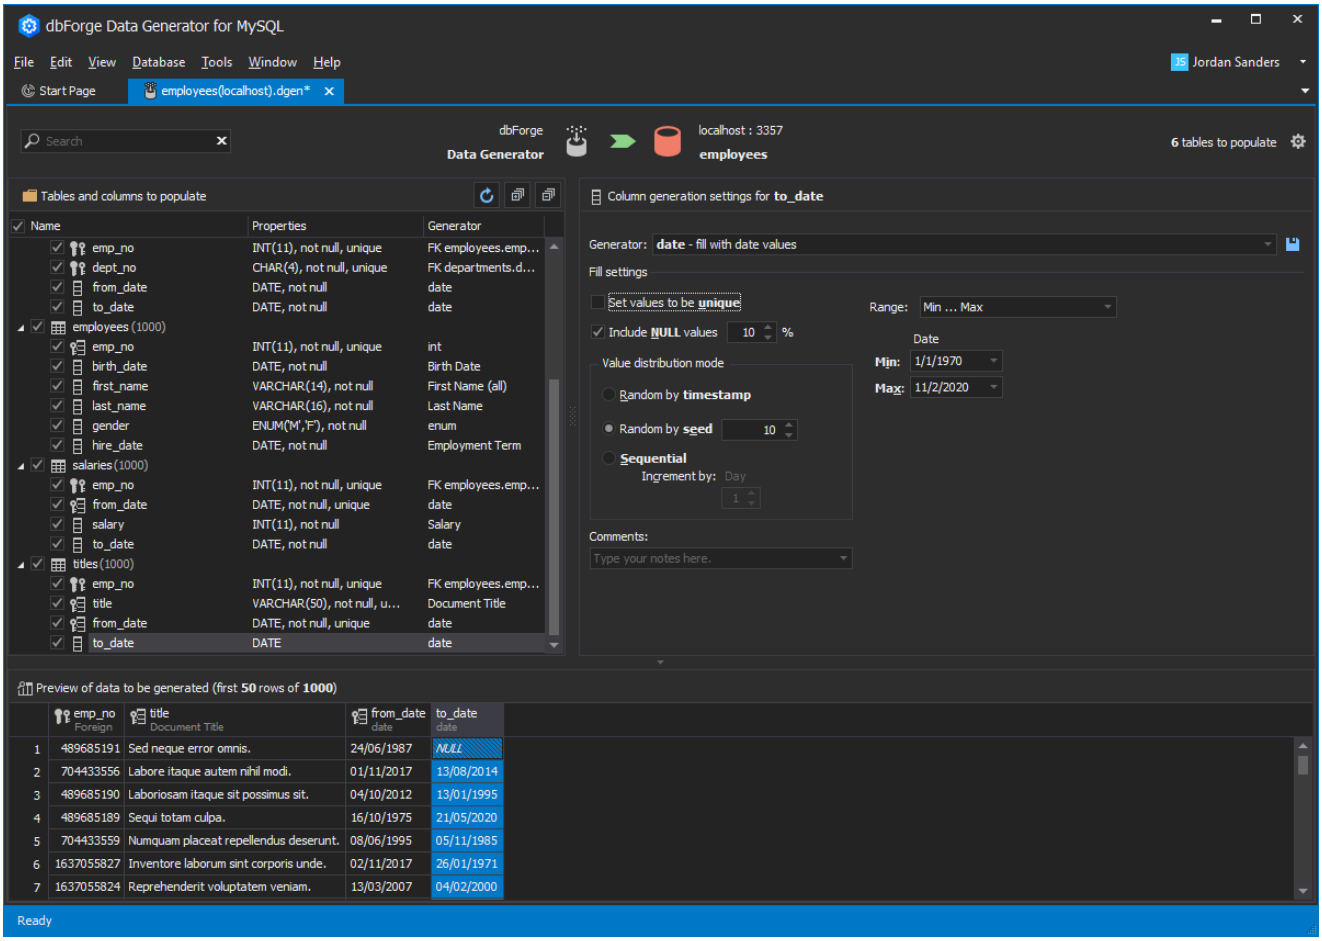
Enjoy the advantage of various data types support



column-data-types

2. Multiple generators with unique test data

Enjoy multiple customization options with individual generators for every data type supported



custom-options

3. MariaDB data generation and data integrity support

Generate consistent random data through multiple tables

Disable triggers and constraints to avoid interference with database logic

4. MariaDB data distribution modes

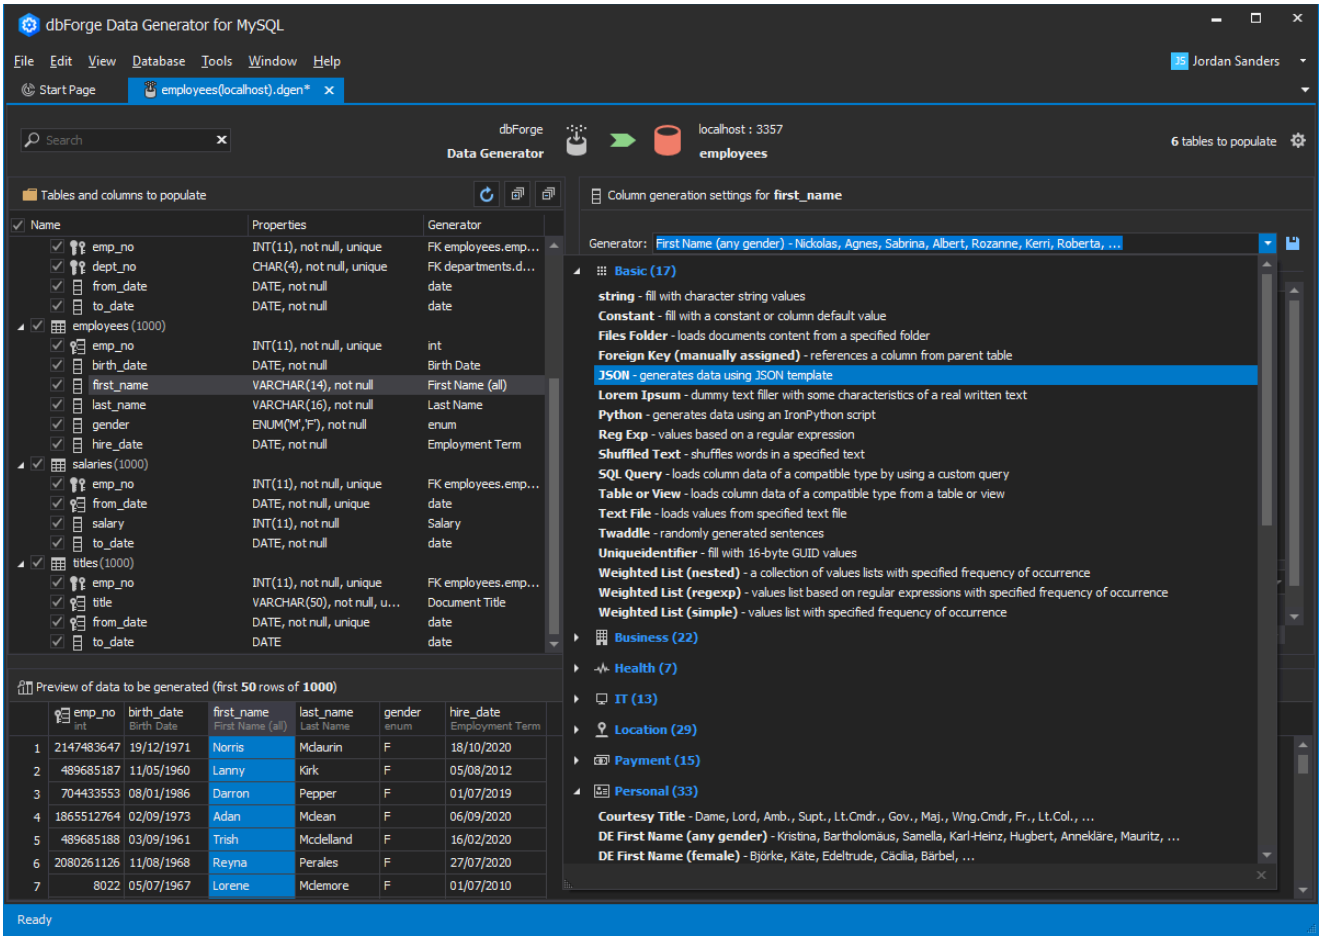
Fine-tune the way you want your data to be generated

5. Multiple ways to generate data in MySQL

Generate a data population script, execute it against a MariaDB database, save or edit it later

6. Basic generators

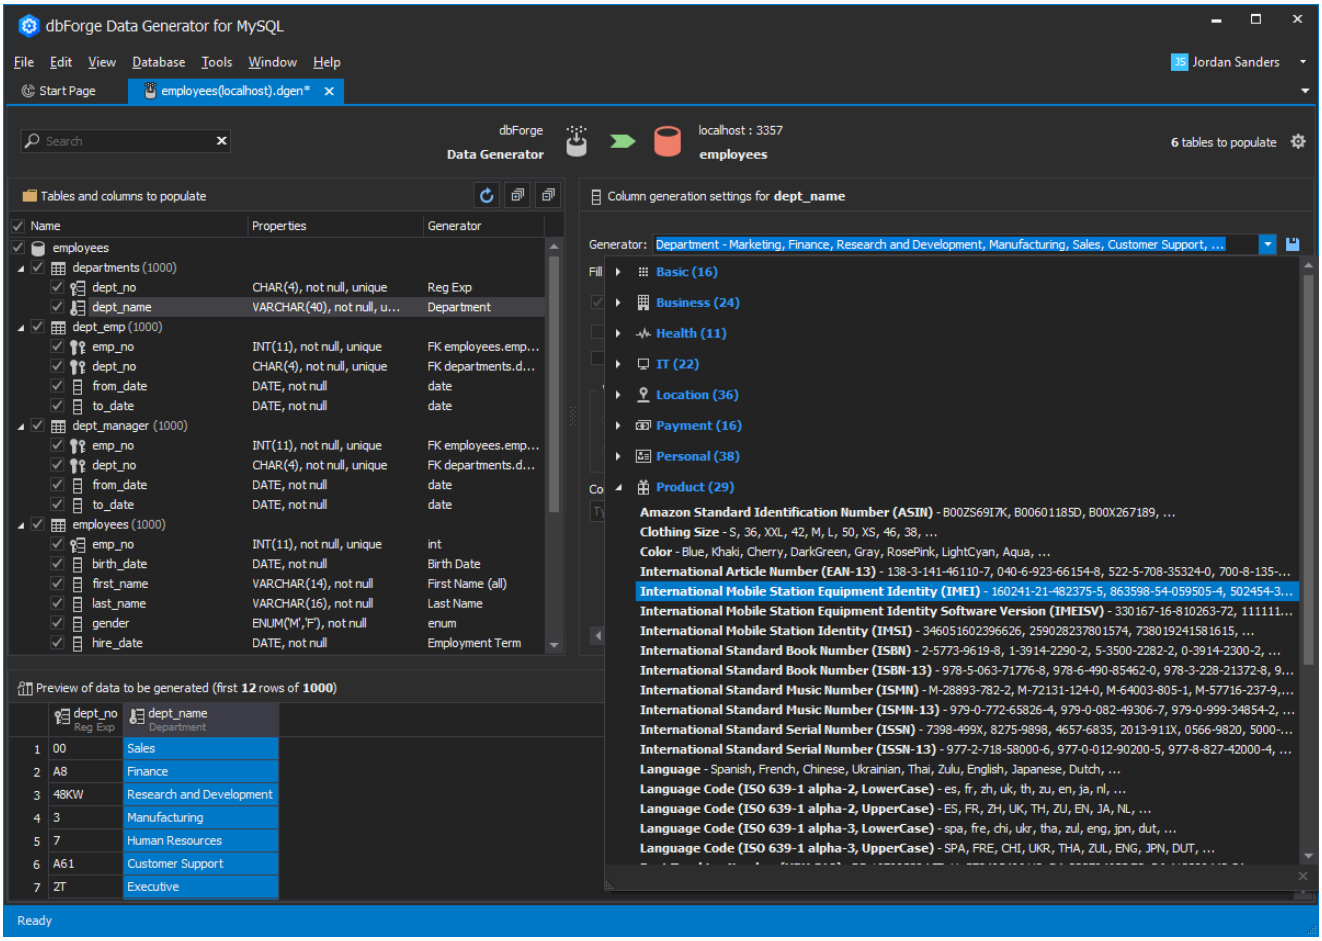
Populate tables with a great variety of values types, like JSON, Python, XML, etc.



basic-generators-1

7. Meaningful test data generators

Select any of 200+ real-world generators and populate tables with realistic data related to various spheres



meaningful-generators-1

8. User-defined generators

Create, save and use your own data generators tailored for your needs

9. Real-time data generation preview

Enjoy real-time visualization of the alterations you make

Visually assess the data to be generated

10. Command-line interface

Schedule your routine data generation tasks

Create a command line execution file for running database documentation tasks

11. Broad compatibility options

MariaDB server versions 5.5-11.4

Various cloud services: Amazon RDS, Amazon Aurora, Google Cloud, Oracle MySQL Cloud, Alibaba Cloud

Security connections: Secure Socket Layer (SSL), Secure Shell (SSH), HTTP Tunneling, PAM Percona

dbForge Documenter

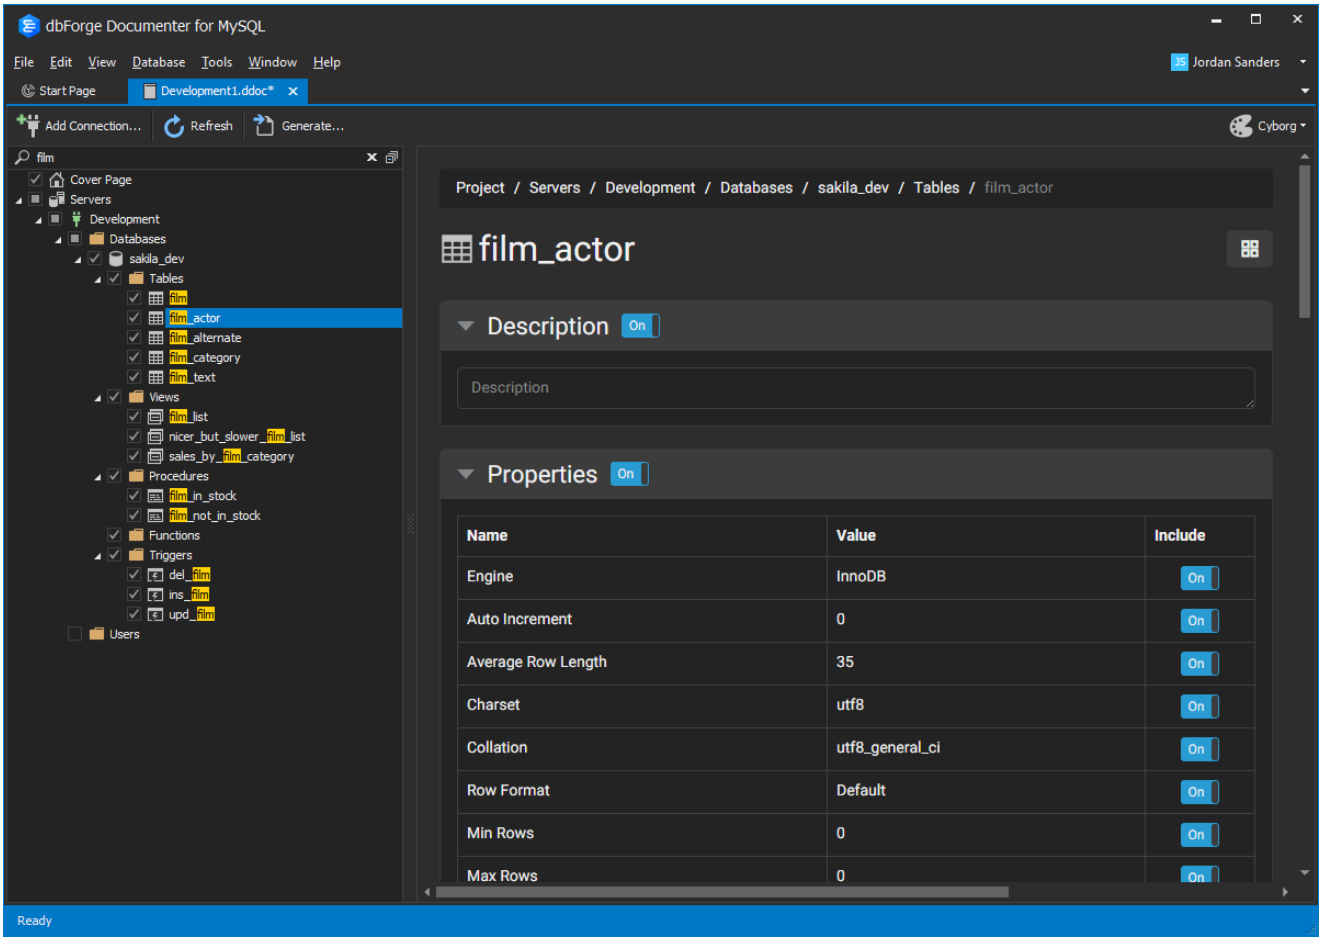
> **Note:**
>
> dbForge Documenter is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

dbForge Documenter is a useful tool for the MariaDB database that allows for the automatic generation of database documentation in such formats as HTML, PDF, and Markdown. Users can adjust the created documentation with a great variety of options.

Features are described in the following.

Searchable MariaDB & MySQL Documentation

Search as you type. View the highlighted matching text after entering the name of a required object in the search field.



Compatibility Options

Various cloud services: Amazon RDS, Amazon Aurora, Google Cloud, Oracle MySQL Cloud, Alibaba Cloud,

Security connections: Secure Socket Layer (SSL), Secure Shell (SSH), HTTP Tunneling, PAM Percona.

compatibility

Database Structure

Detailed MariaDB database information, such as types, details, and properties of the objects, inter-object dependencies, and DDL codes.

dbForge Edge

> **Note:**
>
> dbForge Edge is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

dbForge Edge is a versatile software solution designed to meet the needs of full-stack database specialists. It offers a wide range of features to address database challenges across major providers: MySQL/MariaDB, SQL Server, Oracle, and PostgreSQL. When it comes to MySQL and MariaDB, dbForge Edge provides a highly functional IDE that covers almost all aspects of database development and management.

Features are described in the following.

Design

dbForge Edge includes a built-in Database Designer equipped with ER diagrams, allowing users to construct and edit databases. An intuitive interface facilitates the creation of database structures and generation of reusable SQL scripts for creating actual databases. Table Designer is a separate feature for visual creation and management of tables that covers the setup of columns, data types, constraints, etc.

SQL Development

dbForge Edge offers a powerful set of features to simplify SQL coding tasks. The code assistance module offers context-based keyword and object suggestions, code completion, instant syntax validation, customizable code formatting profiles, debugging, and code refactoring capabilities. Another feature worth mentioning is Query Builder – a tool that allows users to construct even the most complex SQL queries effortlessly in a visual mode.

Database Management

The solution incorporates schema and data comparison tools, enabling users to identify and manage differences in database schemas and table data. With automatically generated synchronization scripts, changes can be seamlessly deployed to target platforms. Comparison and synchronization jobs can also be automated, improving user efficiency.

dbForge Edge supports data migration (import and export) in over 10 major data formats. Both the import and export processes can be tailored to meet any specific requirements and automated for efficient workflows.

Also, dbForge Edge delivers Source Control, an integrated tool that enables version control of database schemas and static data, available for MariaDB, MySQL, and SQL Server databases. With its help, users can compare database versions, commit and revert changes with dependency awareness, view and resolve conflicts, and examine the history of changes. Source Control supports all popular version control systems, such as Git (including GitHub, GitLab, Azure DevOps, and Bitbucket), Apache Subversion (SVN), TFVC, Mercurial (Hg), Perforce (P4), and SourceGear Vault.

Testing

The solution features a robust Data Generator capable of producing high-quality test data in varying volumes and formats. Additionally, the Query Profiler tool enables comprehensive analysis and optimization of queries, thereby saving valuable time and resources.

Security Management

The dedicated module deals with user management configurations. The functionality provided by the software allows easy creation, editing, and management of user accounts and privileges.

Documenting and Reporting

With dbForge Edge, users can create detailed database documentation in various formats and with convenient navigation. The reporting module enables the summarization and analysis of data, presenting comprehensive reports with informative graphs, diagrams, and pivot tables.

dbForge Edge is not just a comprehensive IDE for MySQL and MariaDB. It also serves as an all-in-one solution for database experts who work with multiple database management systems, eliminating the need to assemble toolsets for each. With its extensive feature set, dbForge Edge empowers professionals to efficiently perform their tasks across diverse database environments.

dbForge Fusion

> **Note:**
>
> dbForge Fusion is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

dbForge Fusion is an add-in for Visual Studio. It provides automatic and simple MariaDB database development, and boosts data management capacity. With this tool integrated, it is easy to work with database development and administration tasks from Visual Studio.

> **Note:**
>
> Note: dbForge Fusion is officially discontinued. However, you can access the features available in dbForge Fusion for MySQL/MariaDB through dbForge Studio for MySQL, which is actively supported and regularly updated.

dbForge Query Builder

> **Note:**
>
> dbForge Query Builder is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

dbForge Query Builder is a visual tool that helps create any sort of MariaDB queries. Queries can be drawn on a diagram.

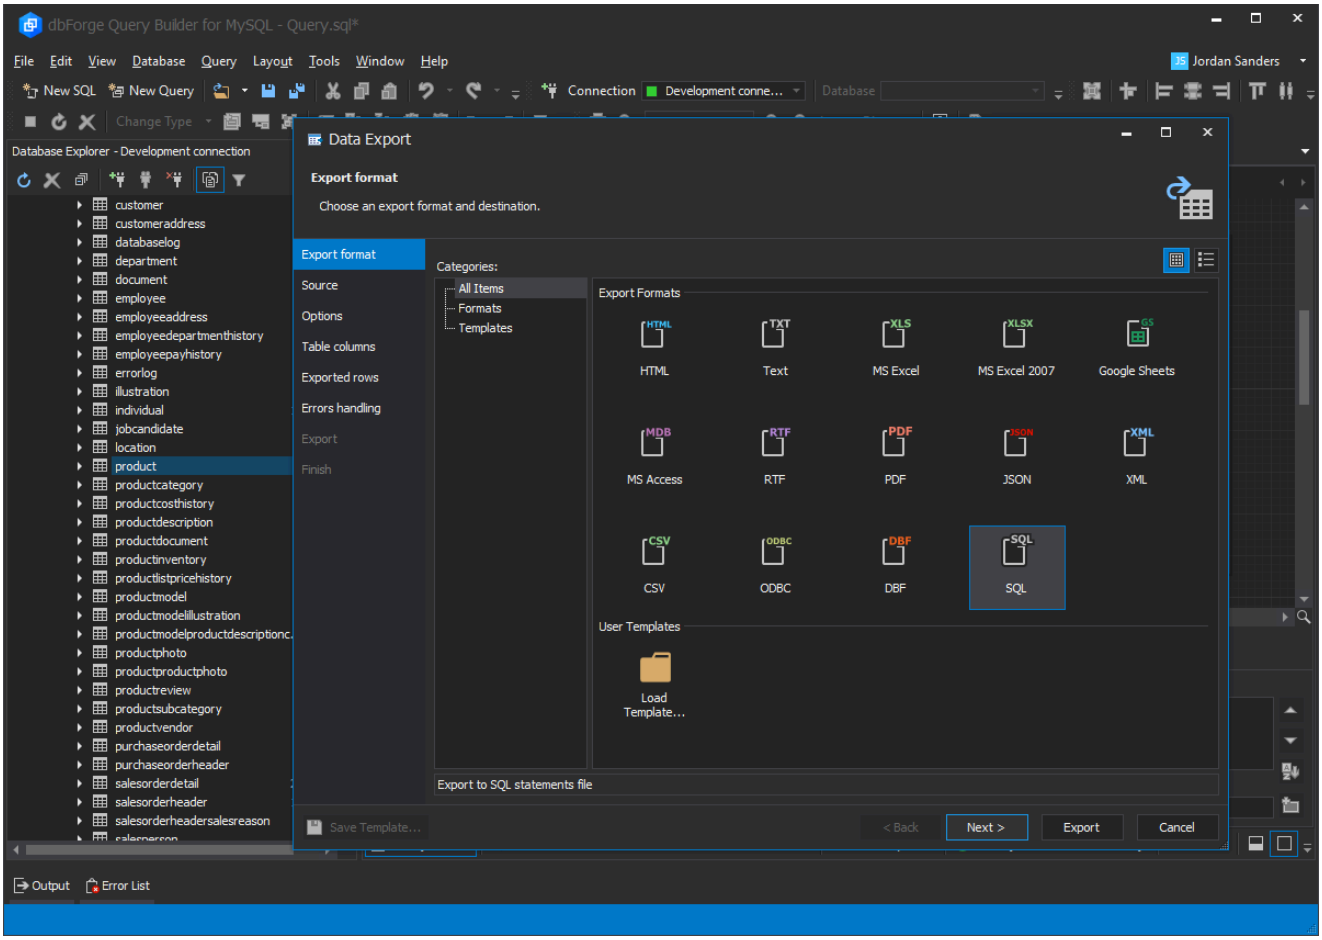
Features are described in the following.

Exporting Data

Export data to many popular formats.

Export data from several tables simultaneously.

Create templates for repeated operations.

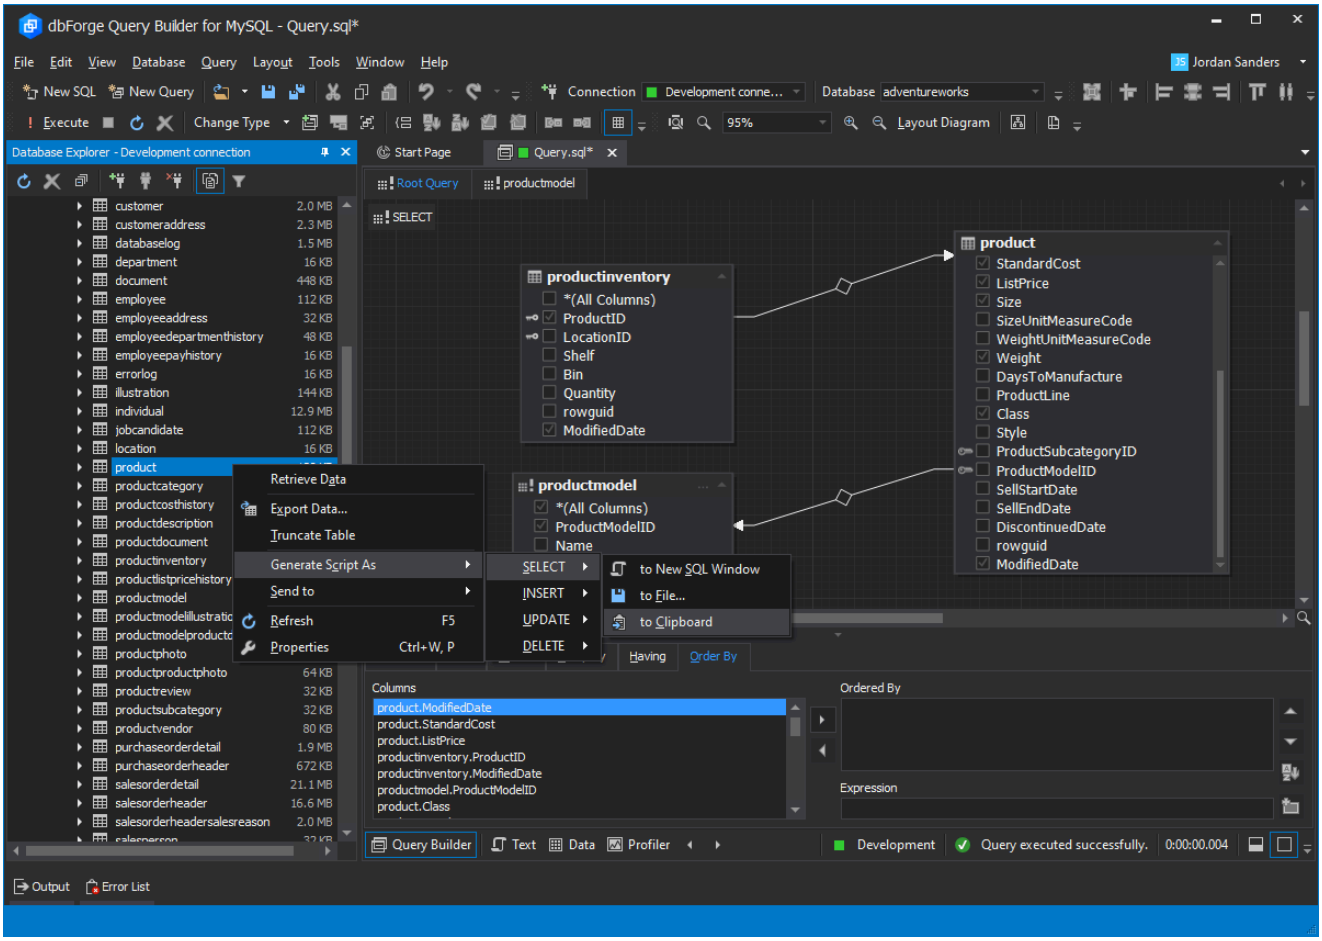


Database Explorer

Work with multiple database connections.

MariaDB query management with drag&drop functionality.

Quick script generation.



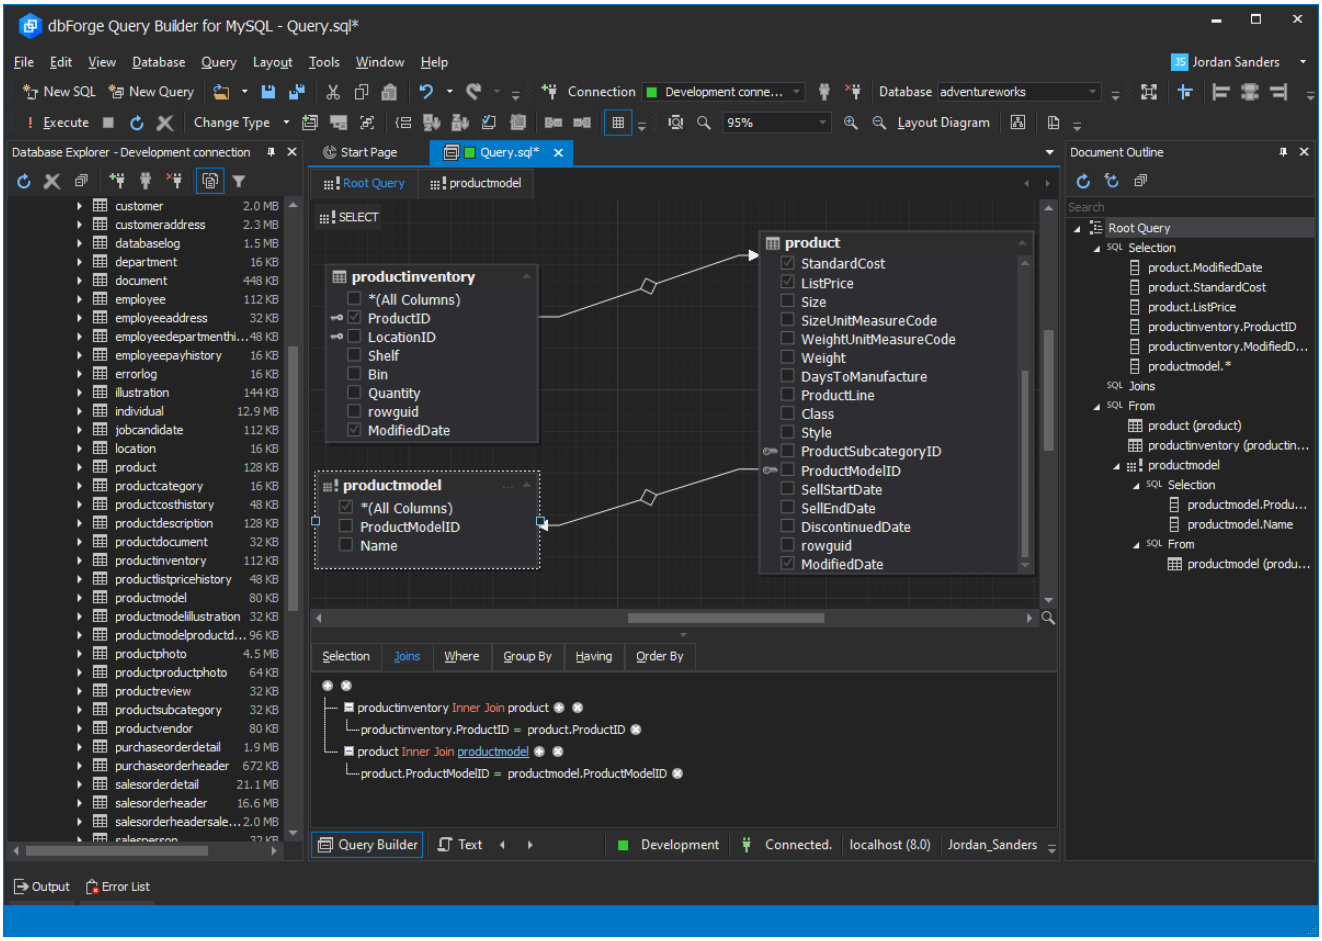
Visual Drag and Drop Query Builder

Zooming and keyboard support in a sophisticated diagram.

Preview and print diagrams.

Add and edit sub-queries visually.

MariaDB JOINs generator.



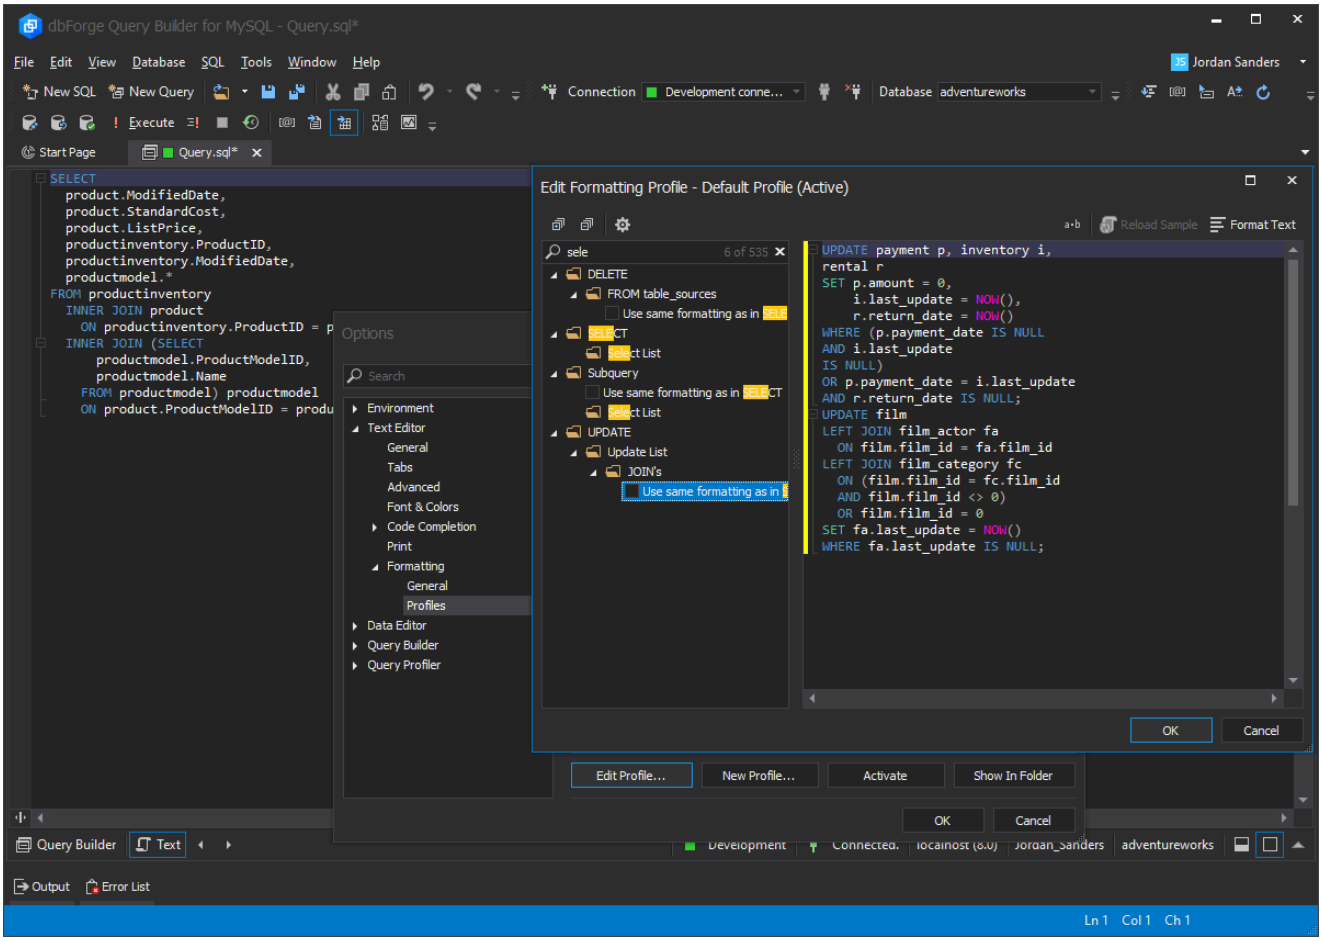
SQL Editing and Execution

Check the syntax automatically.

Get quick information about schema objects.

Customize formatting profiles.

Execute scripts, statements and MariaDB fragments seamlessly.

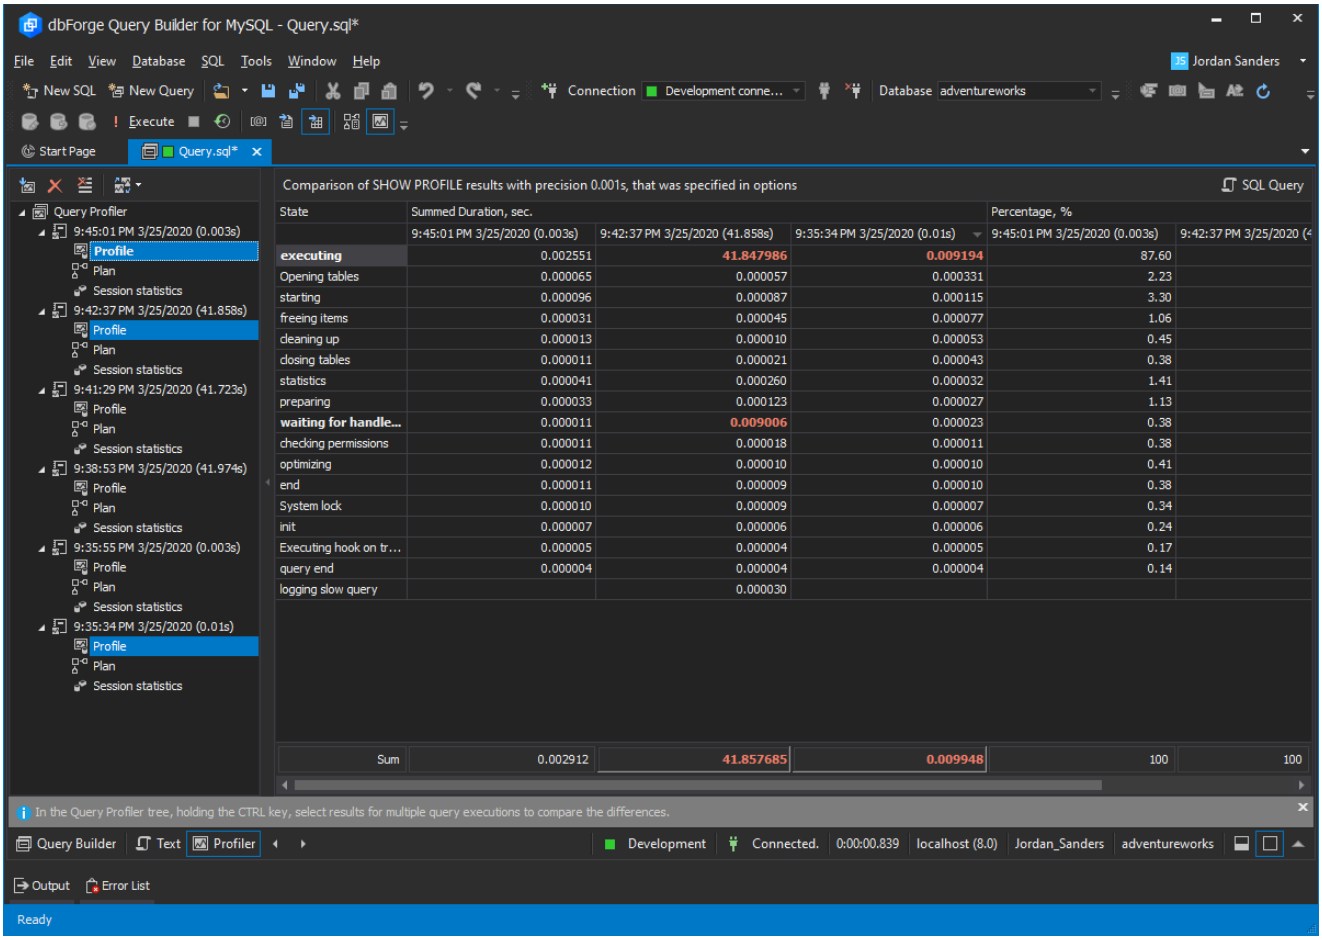


Query Profiler

Compare the results of the query visually.

Review and evaluate a query plan shown in the tree view.

Get the detailed query information.

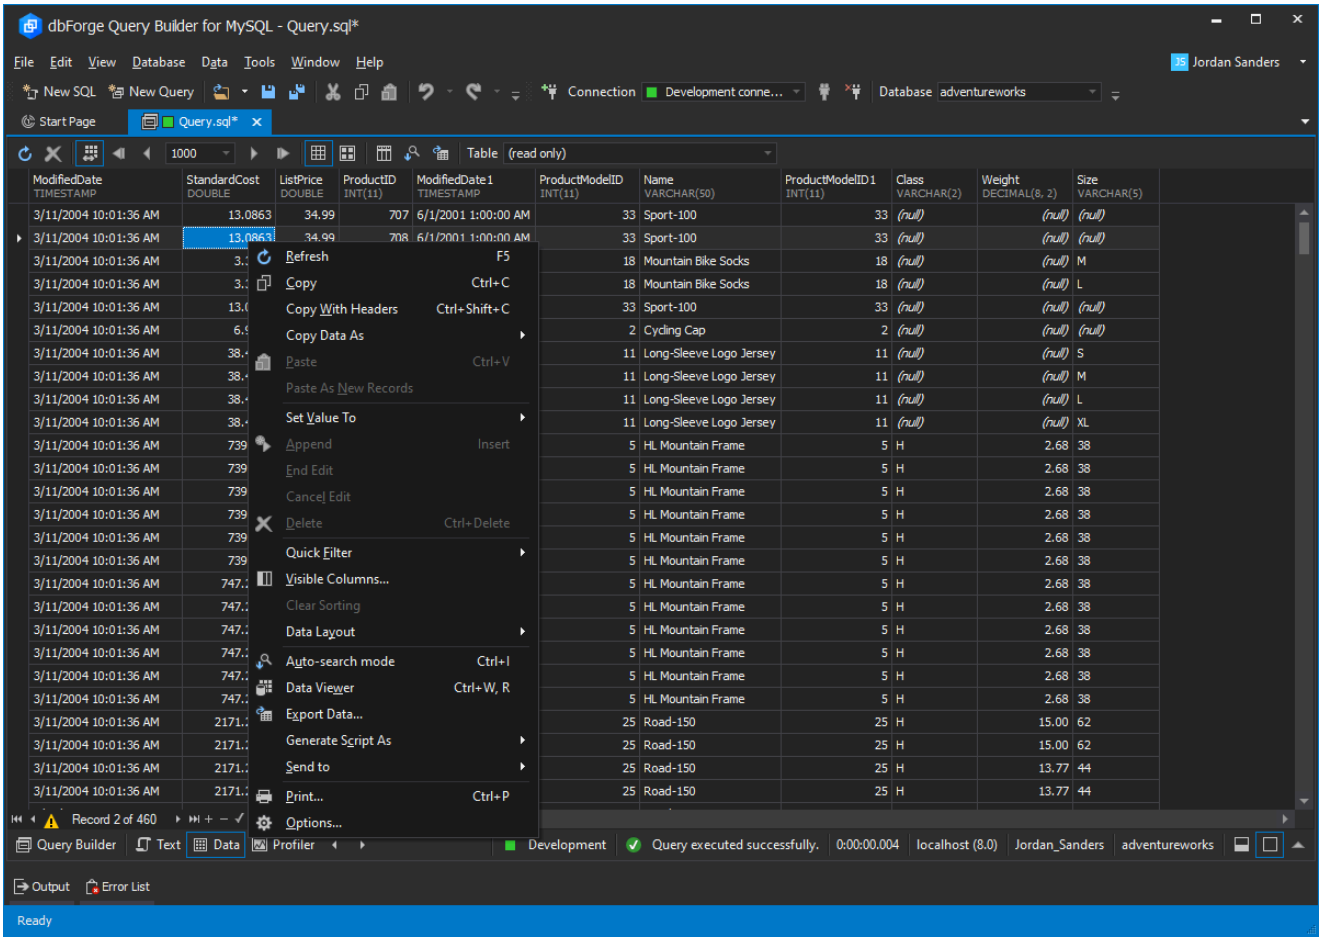


Data Editor

Advanced data filters.

Browse and edit large objects in Data Viewer and Editor windows.

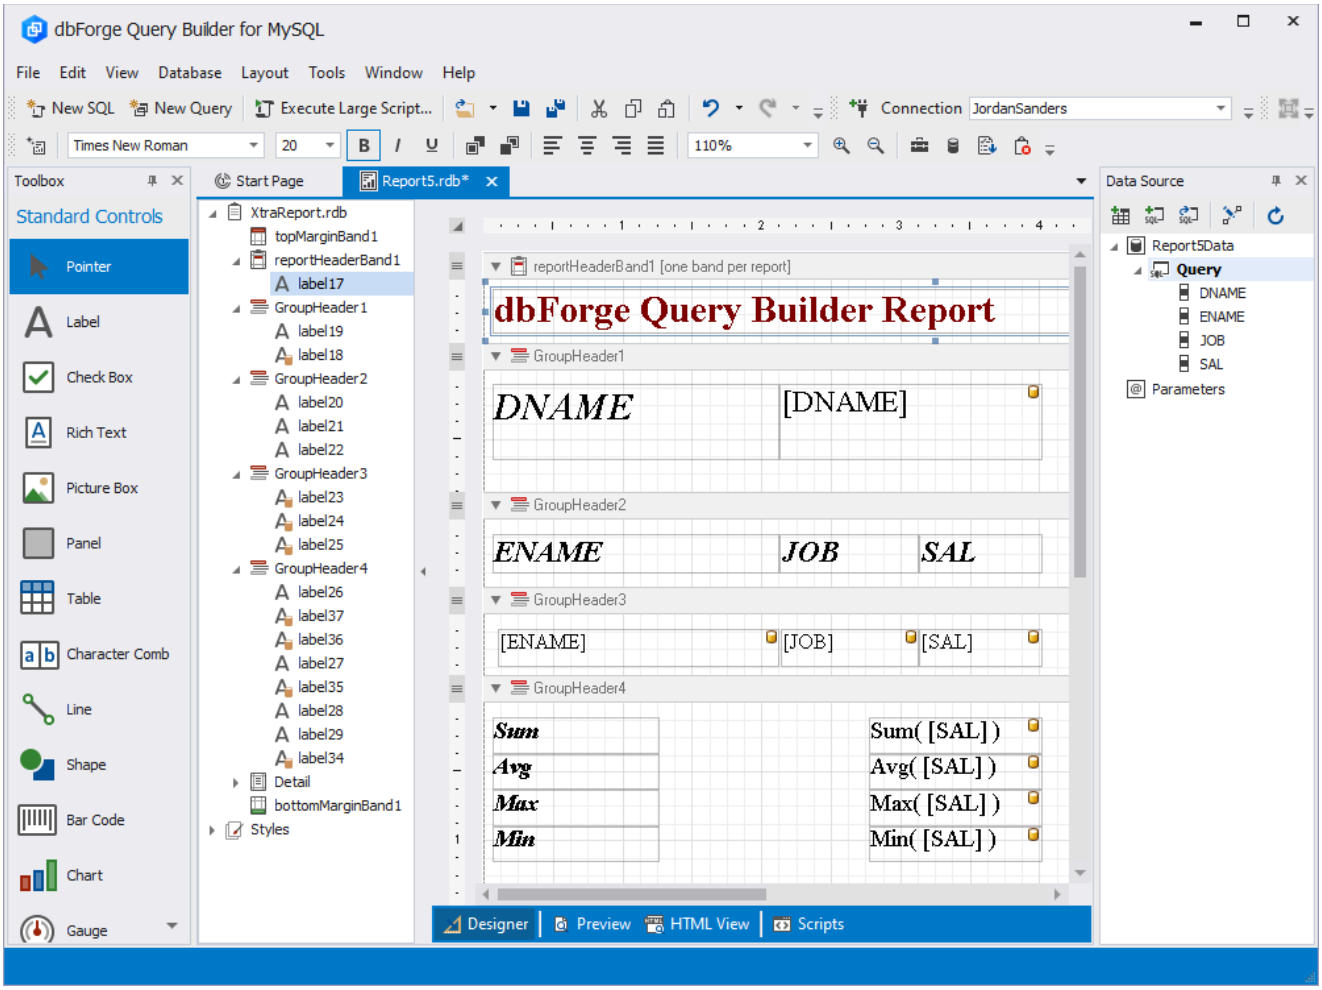
Fetch asynchronous data.



slider-data-editor

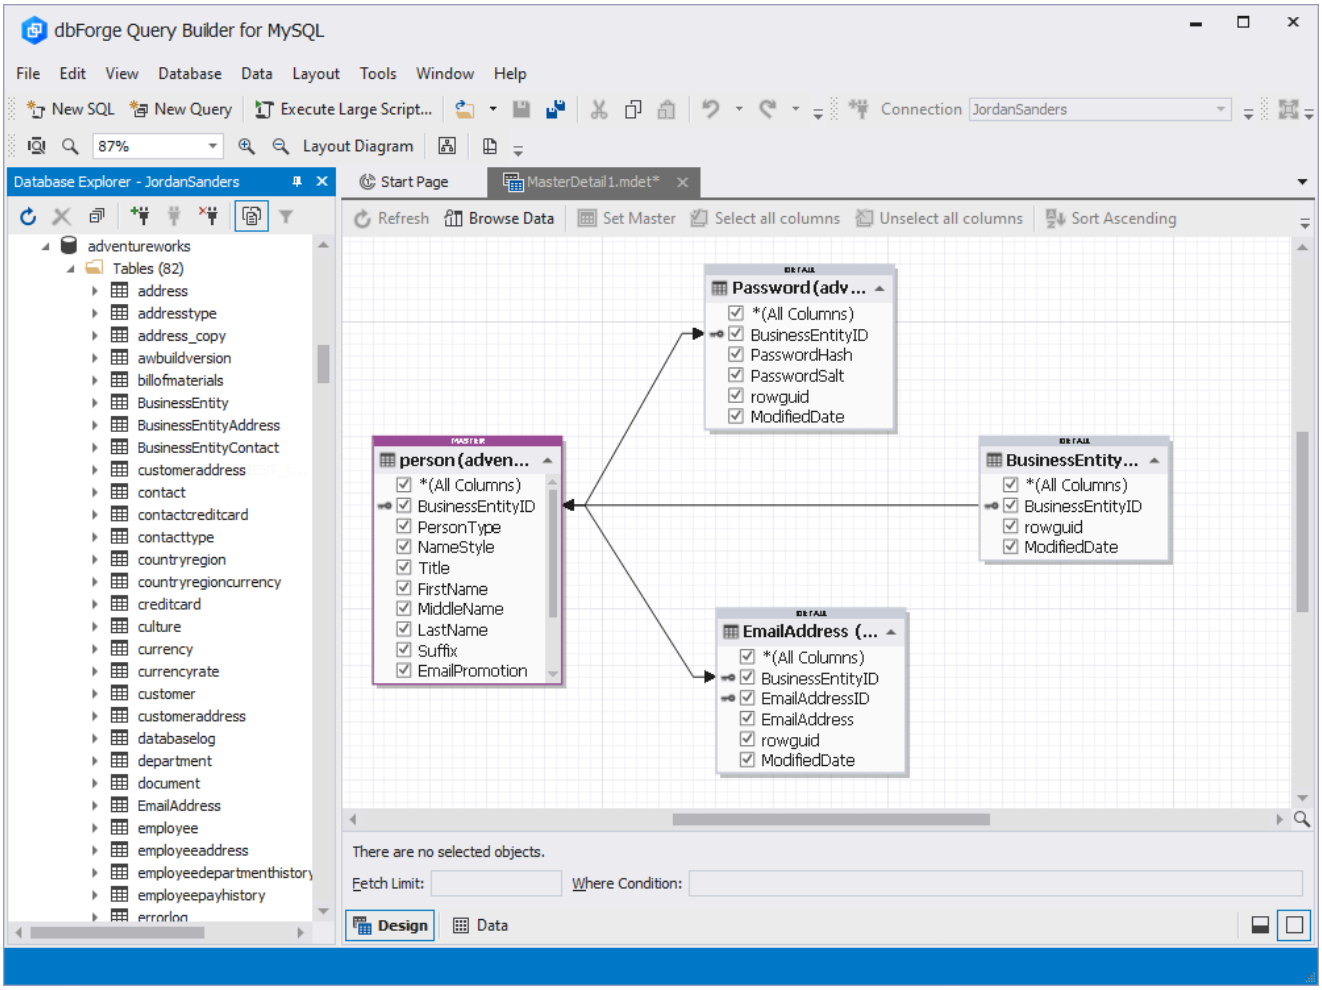
Data Reports

Data Report wizard supports building Data Reports and customizing them with a rich set of controls.



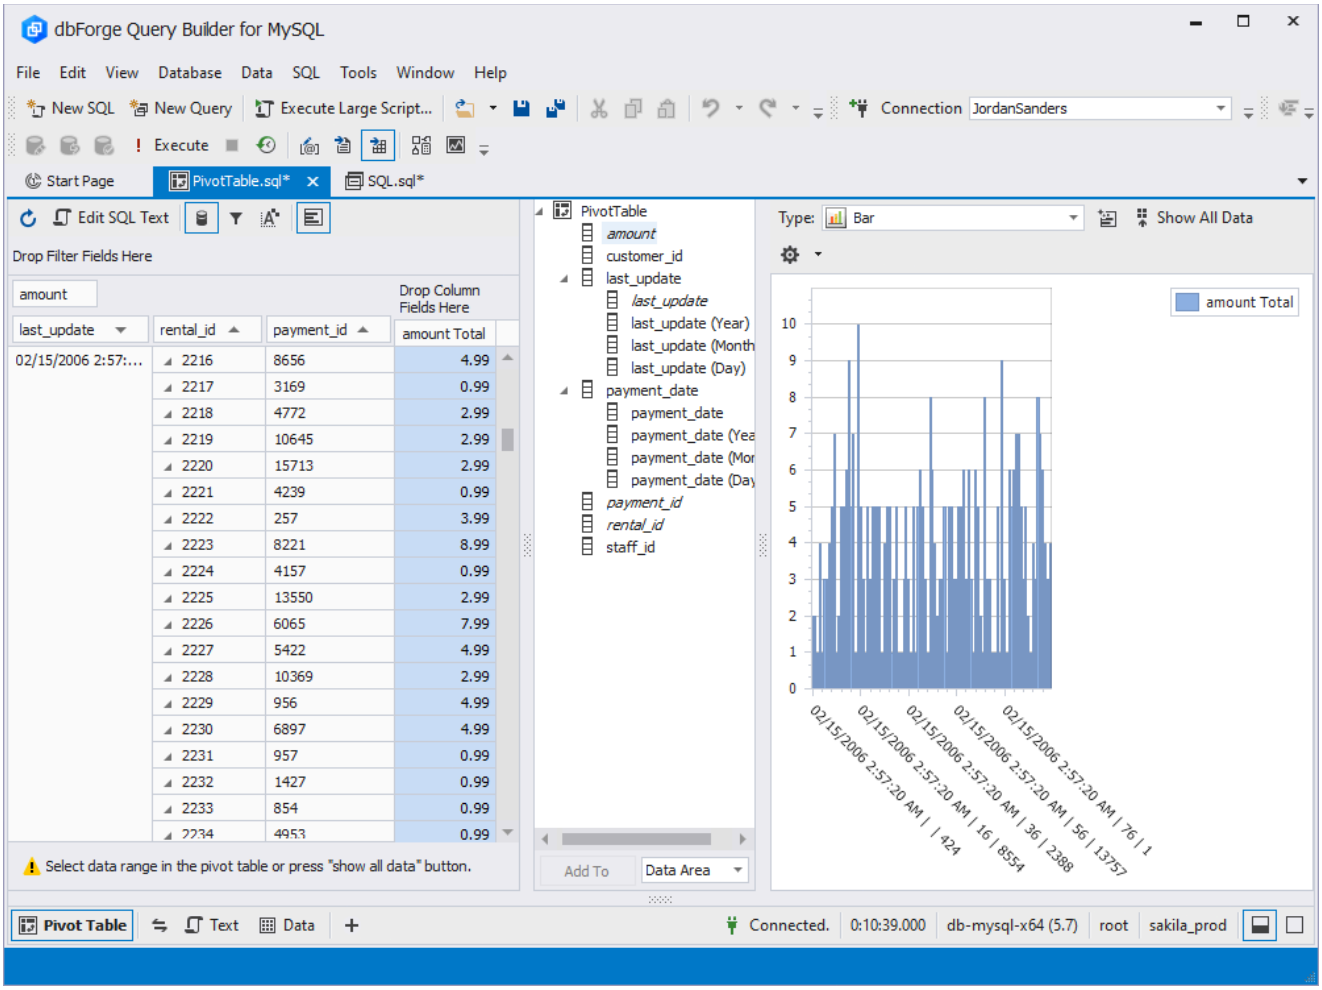
Master-Detail Browser

Allows users to view and analyze the data of several related database objects in a master-detail structured document. Edit data, build relationships, filter data based on specific criteria, sort data, etc. in the Design and Data views.



Pivot Tables

Let users manipulate data visually, including sorting, grouping, or filtering fields, building charts, and calculating totals.



Download a free 30-day trial of dbForge Query Builder for MariaDB here.

Documentation is available, too.

Version	Introduced
dbForge Query Builder 10.1	Support for the rds-ca-rsa2048-g1 SSL/TLS certificate for connecting to MariaDB servers on AWS and enhanced cloud compatibility features, new automation capabilities.
dbForge Query Builder 10.0	MariaDB 11.4, Implemented support for the `JSON_TABLE()` table function in MariaDB.
dbForge Query Builder 5.2	MariaDB 11.3.
dbForge Query Builder 5.1	MariaDB 10.9, MariaDB 10.10.
dbForge Query Builder 4.5	MariaDB 10.5.

dbForge Schema Compare

> **Note:**
>
> dbForge Schema Compare is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

dbForge Schema Compare is a solution that allows for the comparison of the MariaDB database structure. With this tool, you can find the differences in MariaDB database schemas.

Features are described in the following.

MariaDB & MySQL Schema Synchronization

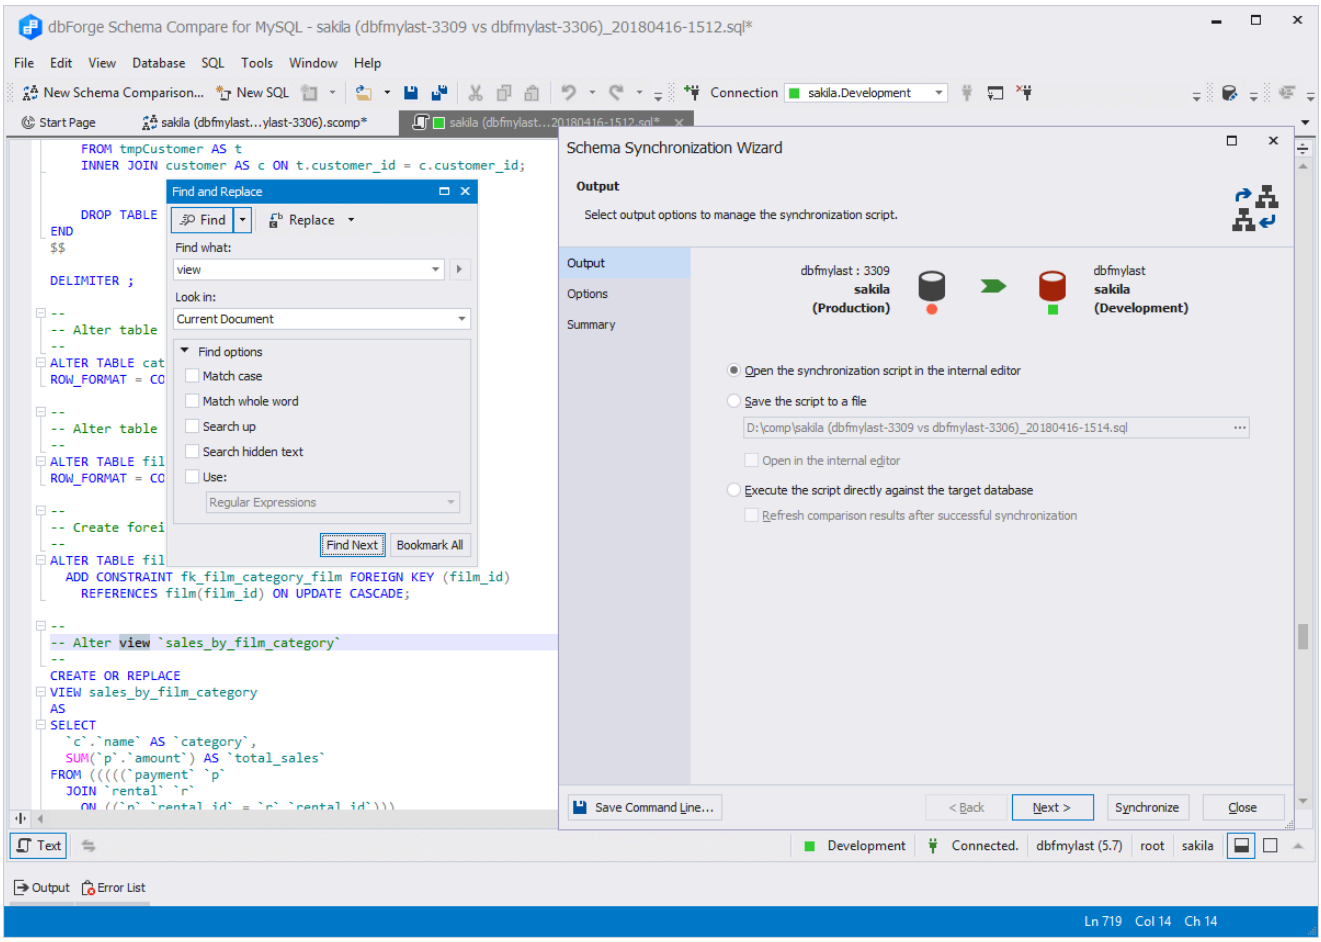
Update MariaDB schemas by generating accurate synchronization scripts.

Preview sync scripts for any schema objects.

Customize the synchronization output with various options.

Get warnings on possible errors while synchronization.

Sync asynchronous structure.



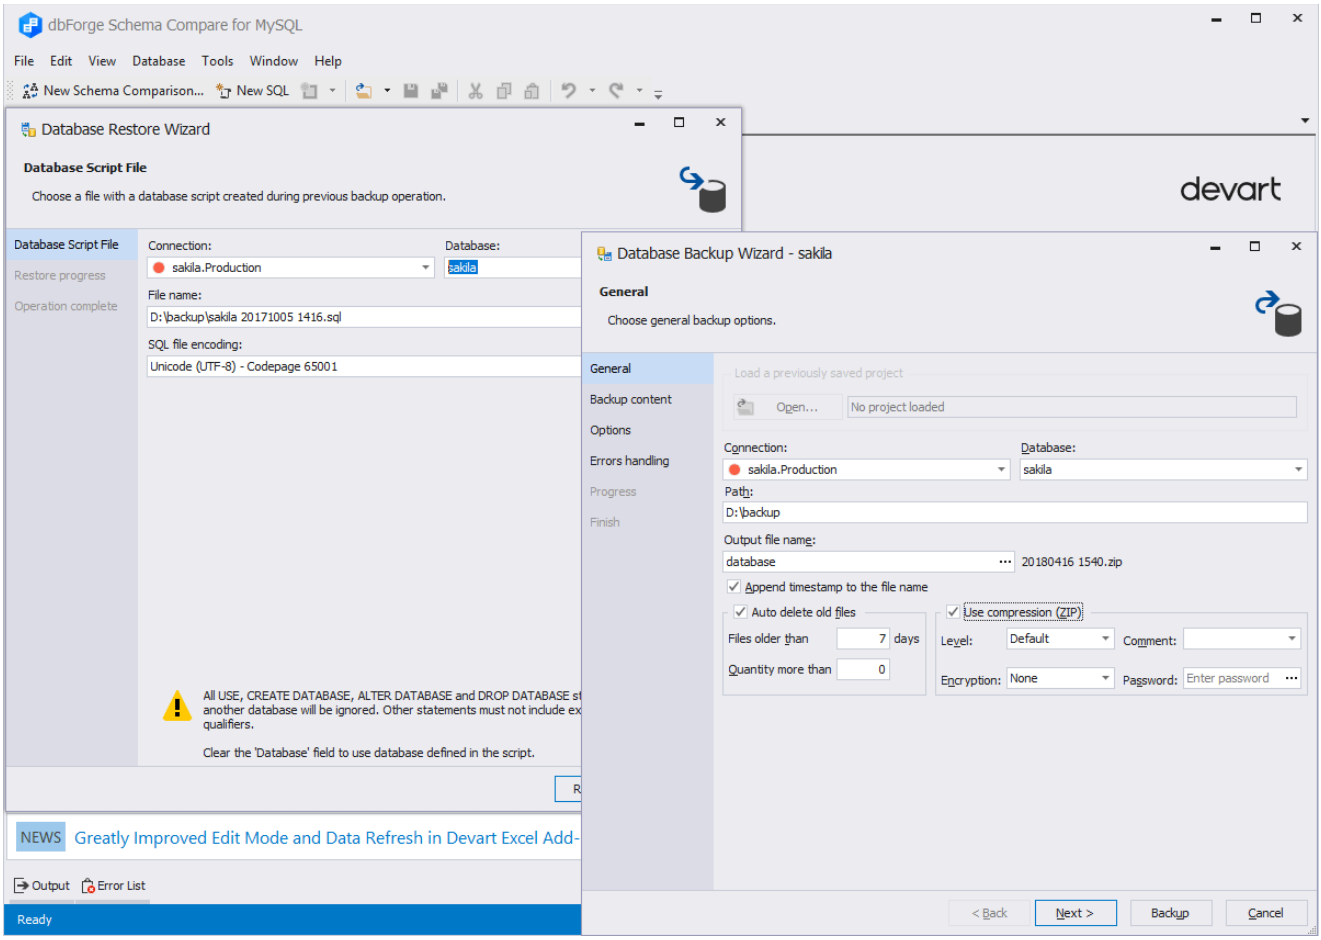
MariaDB Backup and Restore

Use the advantages of MariaDB backup and restore Wizards.

Create a full or partial backup.

Restore database and schedule backups with a command line interface.

Support for databases over 2Gb.

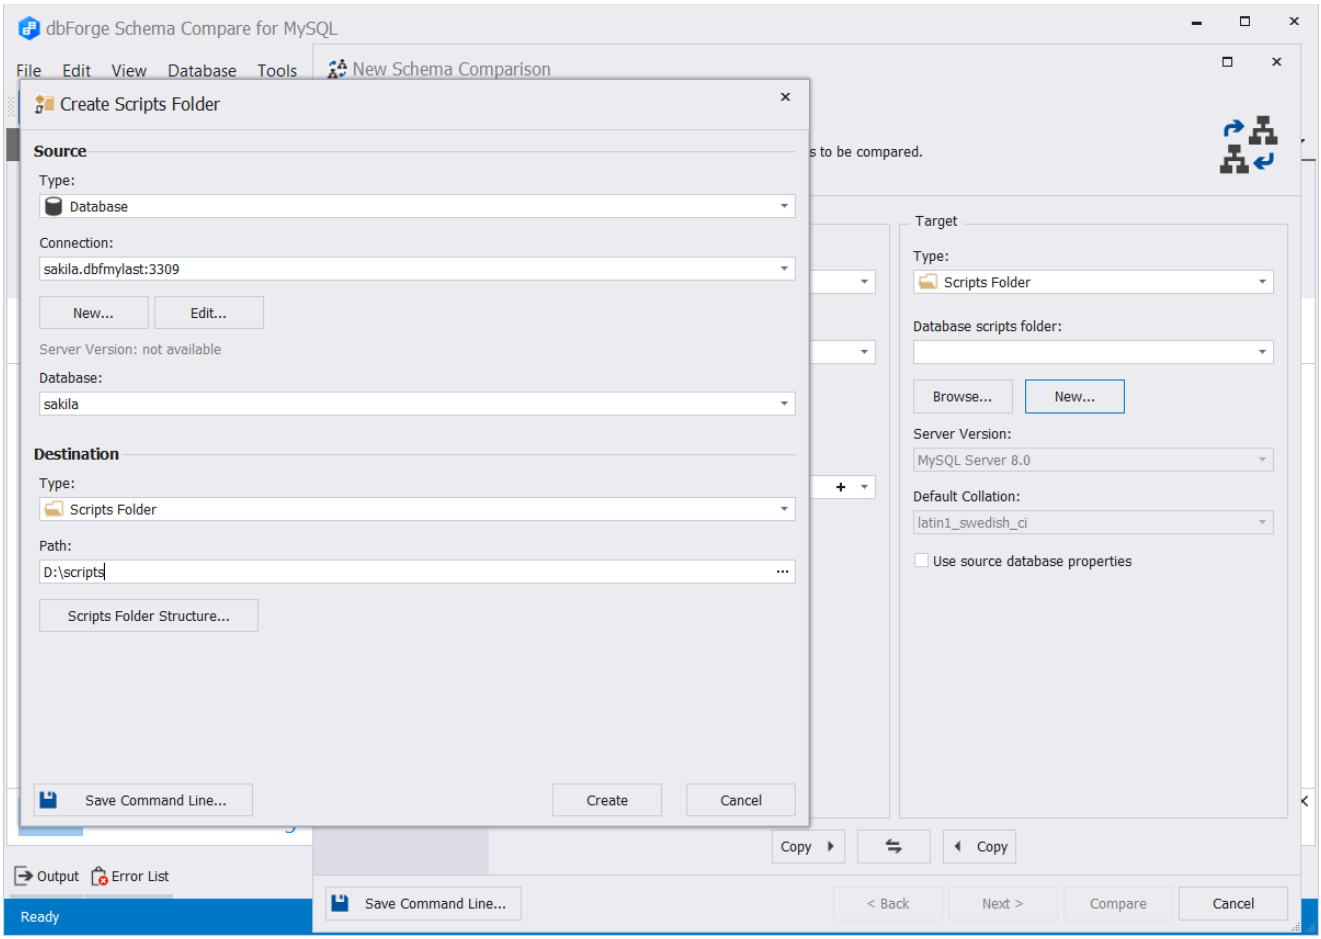


Scripts Folder Comparison

Compare the data both in two different databases and the database data with the data placed locally.

Choose any connection and script folder stored locally with the new Data Comparison Wizard.

View the comparison process results in a data grid.

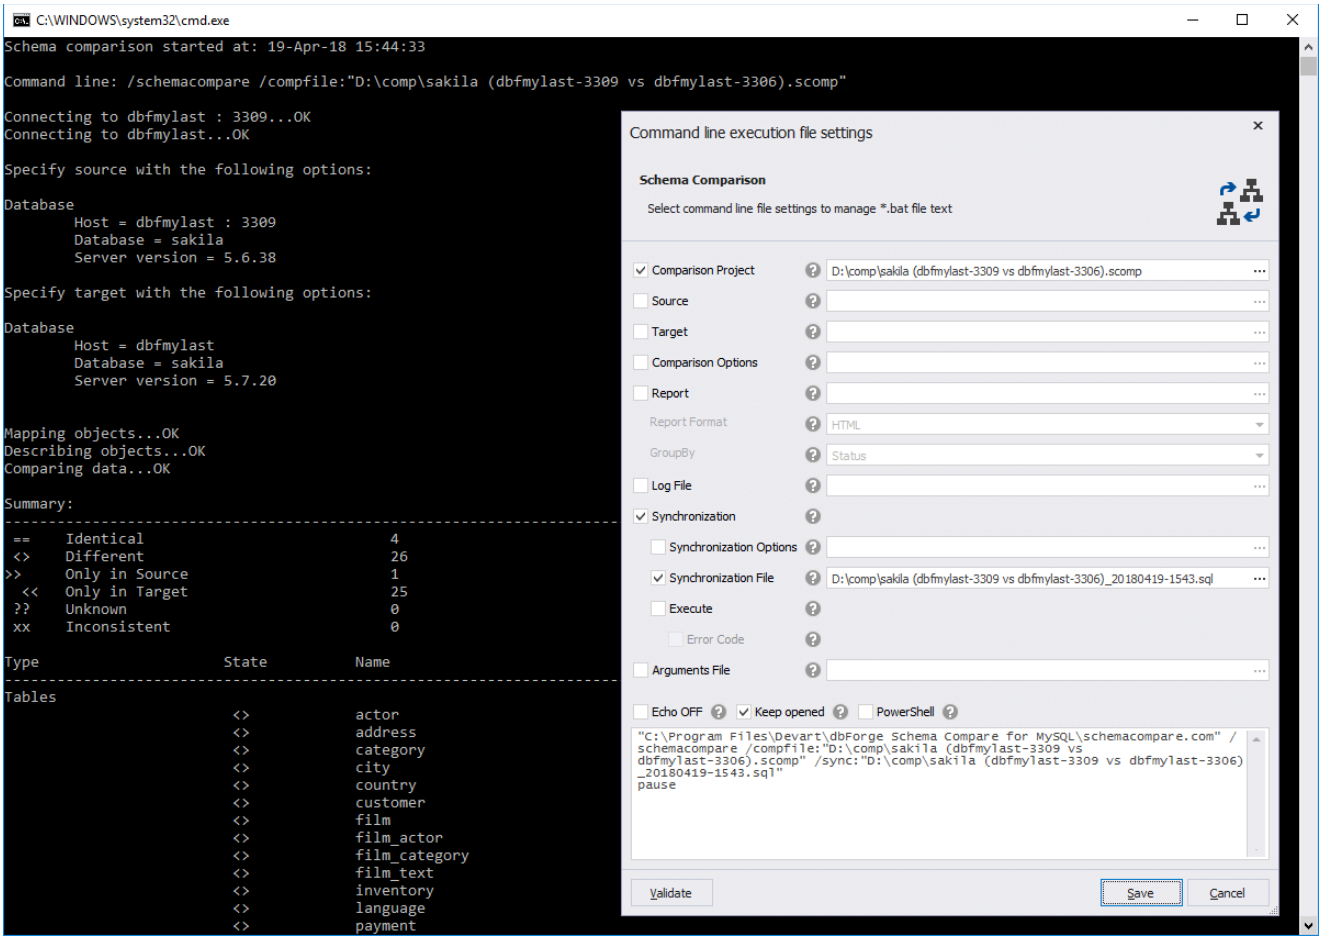


Routine Tasks Automation

Sync and compare database schemas with command line support.

Use the Windows Scheduler to automate the sync processes.

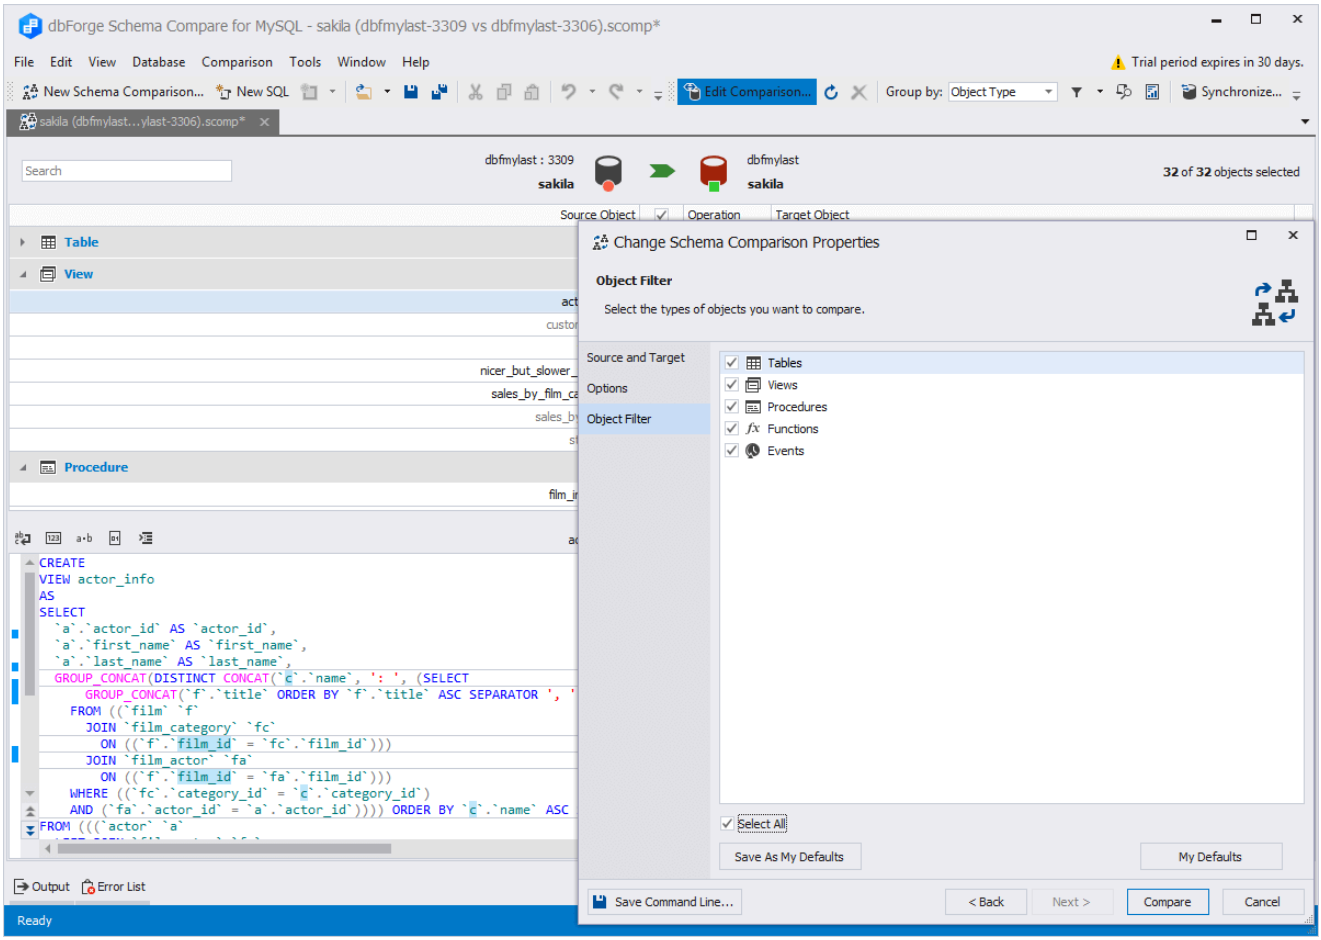
Run synchronization and schema comparison tasks with command line execution files.



Supported Schema Objects

Packages.

Sequences.

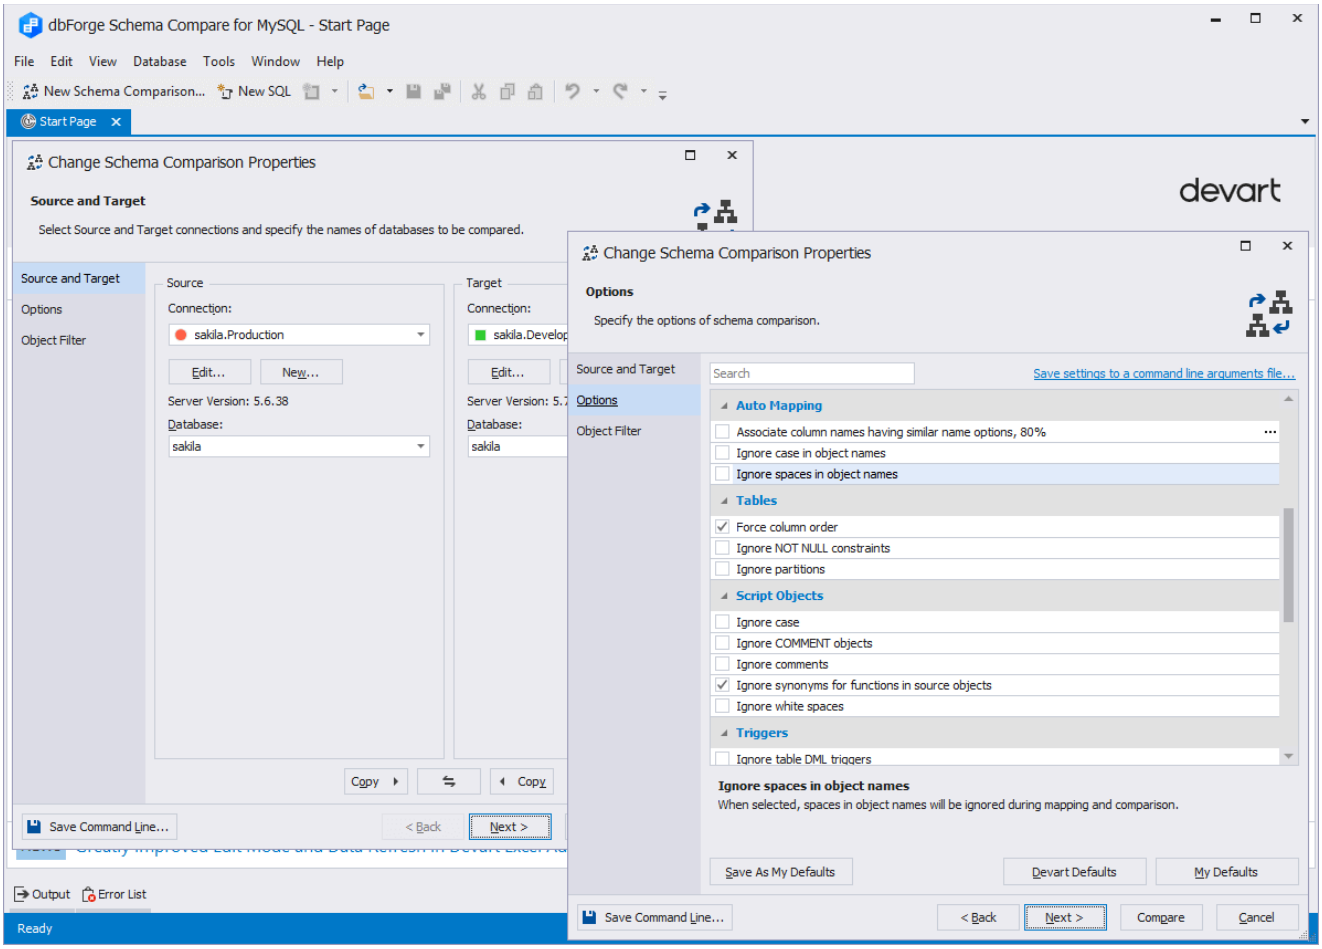


Database Structure Comparison Configuration

Filter the types of objects before the comparison.

Dismiss particular table options while comparing.

Use the Schema Comparison Wizard for switching between the Target and Source databases.

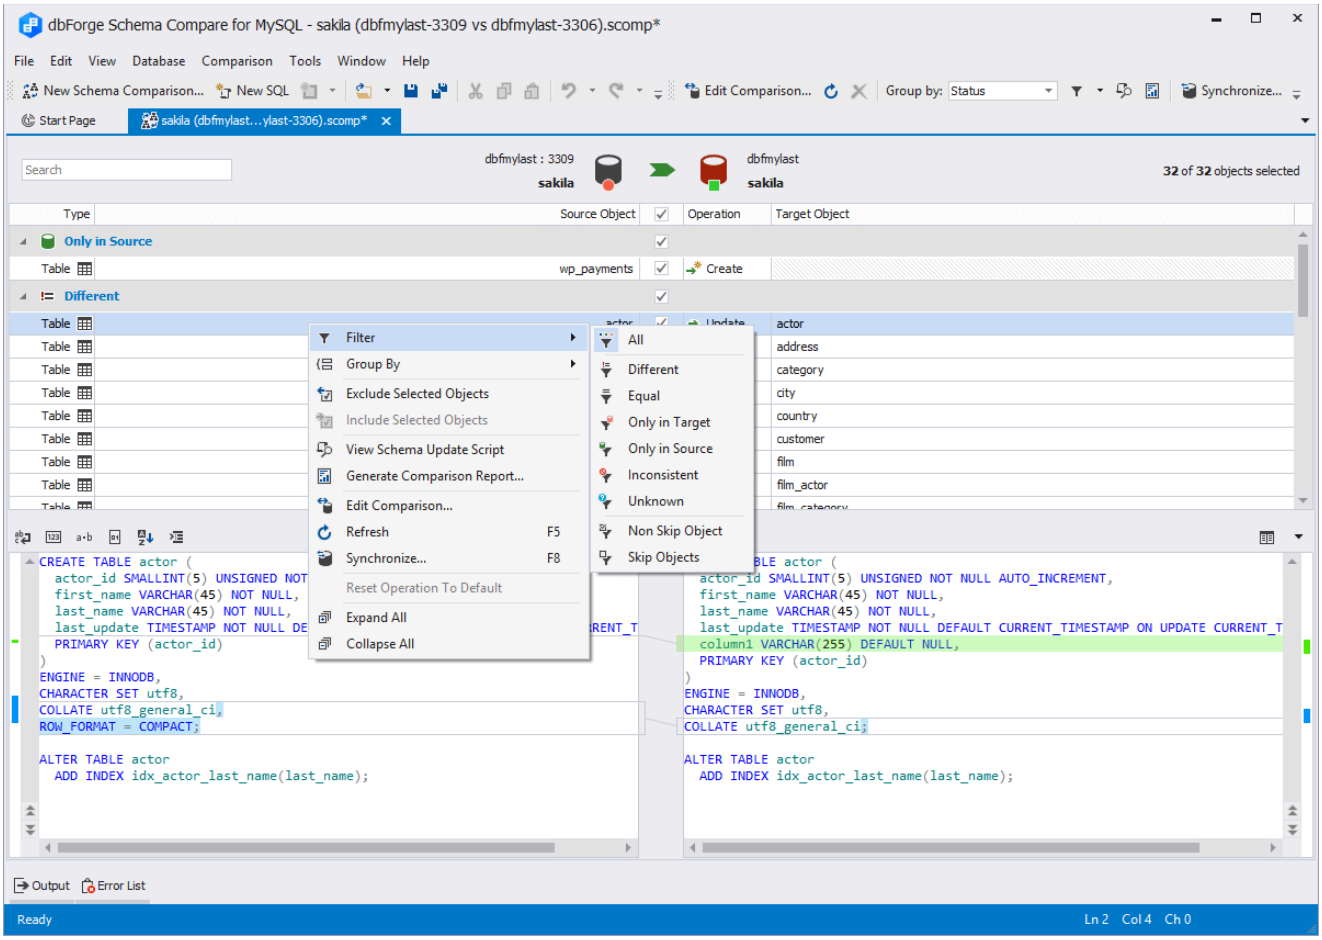


Comparison Results Analysis

Sort and filter the compared objects.

Get a clear view of MariaDB and MySQL schema diffs in the grid.

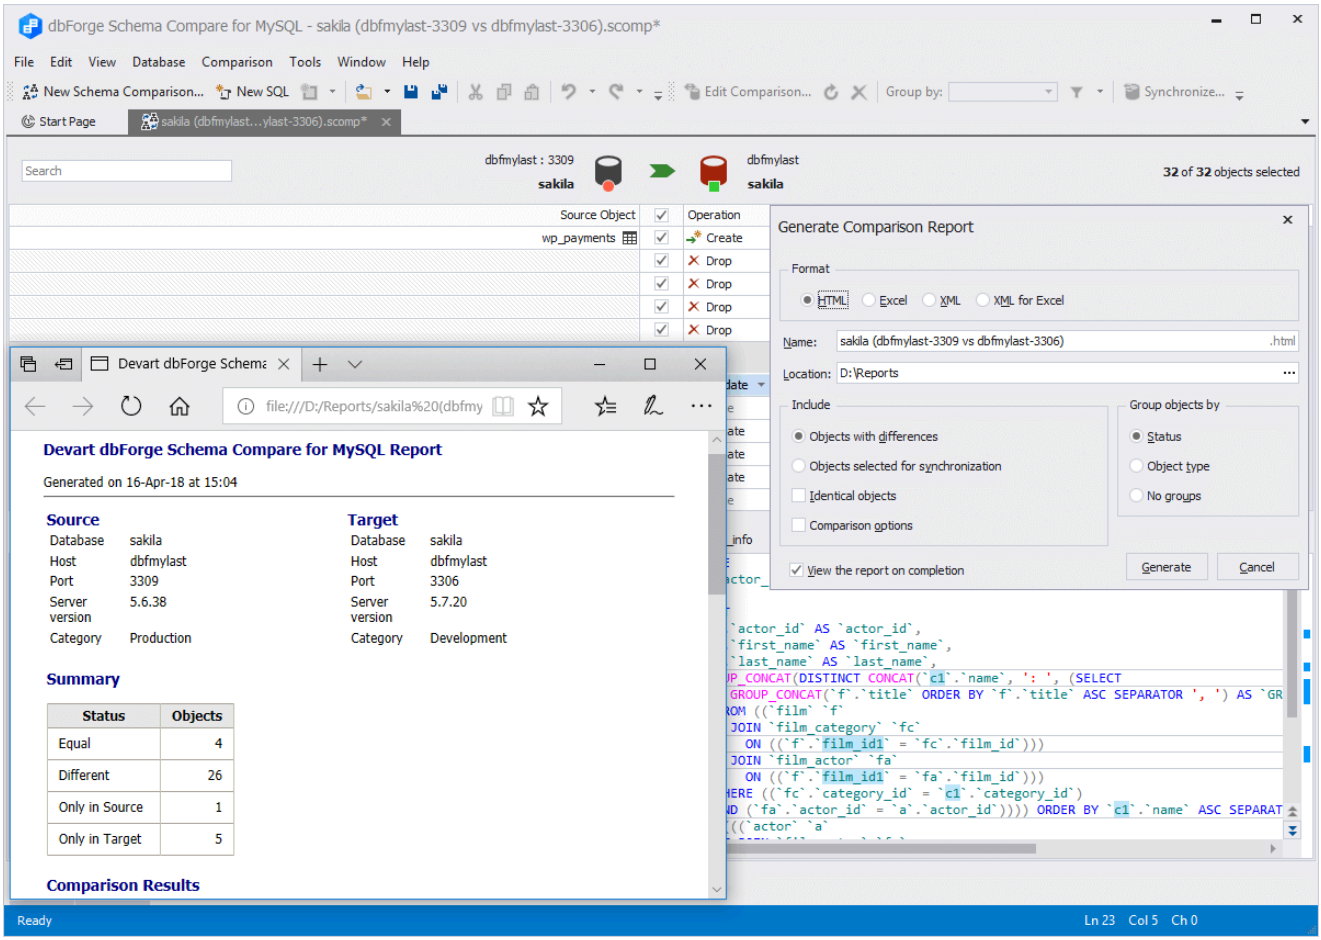
Manage groups of compared objects.



Comparison Results Export

Generate comparison results reports in HTML, Excel XML, XML for Excel.

Include specifically selected objects in your comparison report.



Compatibility

All MariaDB instances set up on Windows, Linux, FreeBSD, etc.

Various cloud services: Amazon RDS, Amazon Aurora, Google Cloud, Oracle MySQL Cloud, Alibaba Cloud.

Security connections: Secure Socket Layer (SSL), Secure Shell (SSH), HTTP Tunneling, PAM Percona.

Download a free 30-day trial of dbForge MariaDB and MySQL Schema Compare here.

dbForge Studio

> **Note:**
>
> dbForge Studio is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

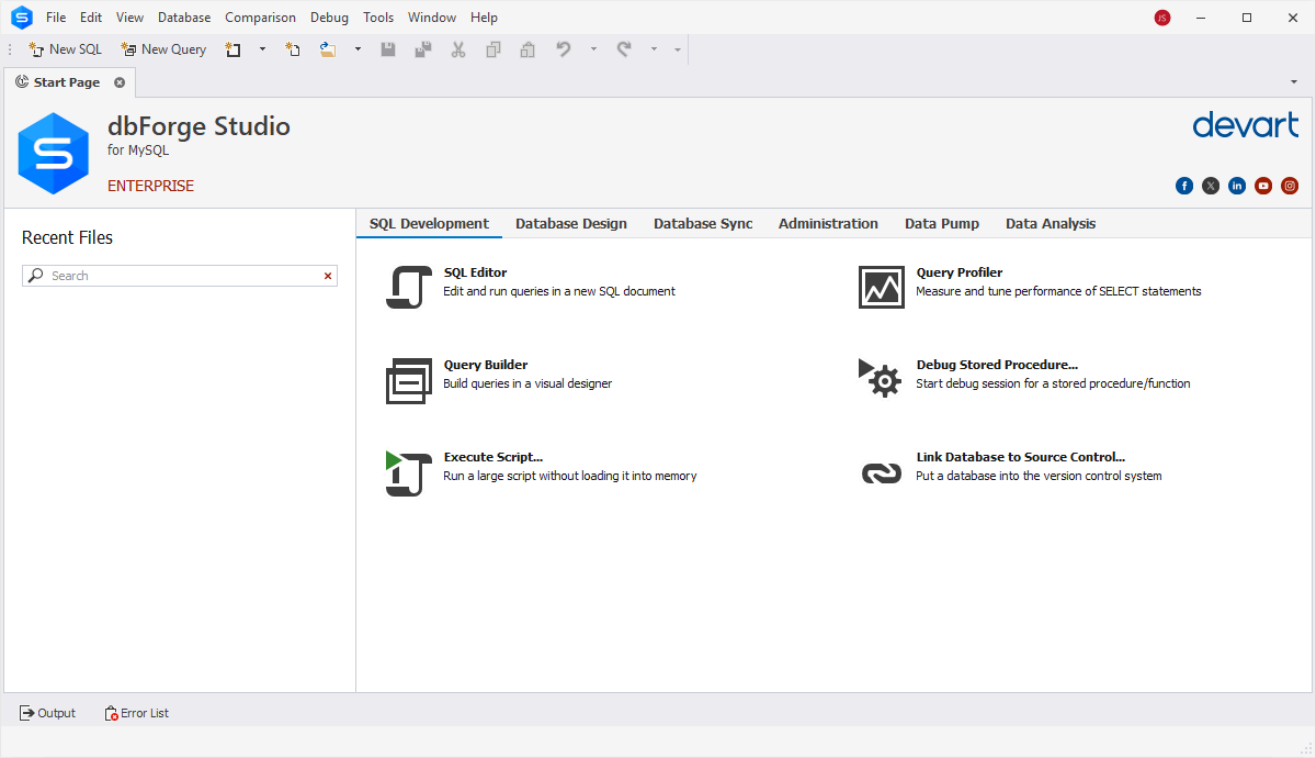
dbForge Studio for MariaDB is a universal IDE with GUI tools that has all the necessary built-in capabilities to work with MariaDB and MySQL databases for their development, management, and administration. It allows for creating, managing, and editing the data without the need to store them locally.

This GUI tool offers a rich visual design that is perfect for working with large scripts, preparing data reports, and database projects. At any time, you can back up or restore your data, export or import them to and from the most commonly used formats, and compare or synchronize the MariaDB databases.

Features are described in the following.

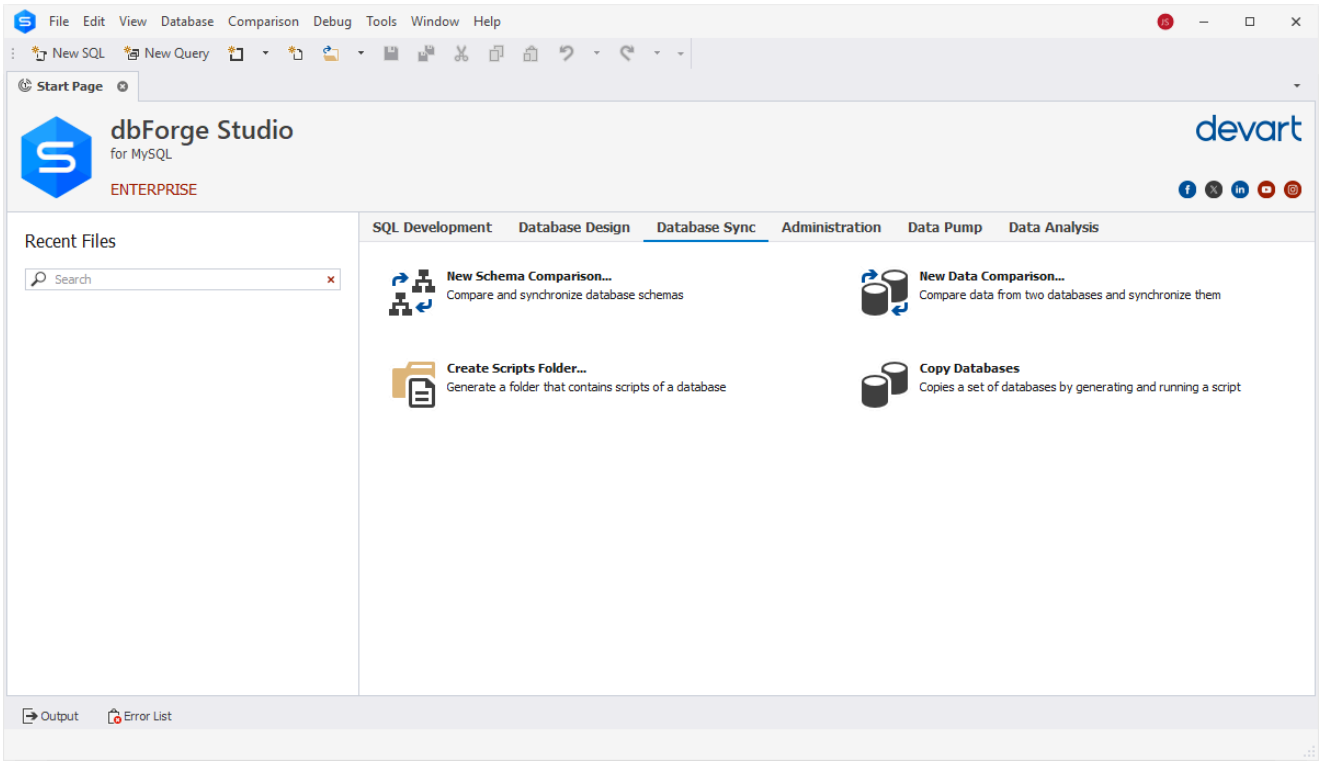
Intelligent SQL Coding

- Automatic code completion.
- MariaDB syntax highlighting.
- Code refactoring and formatting.
- CRUD generation.



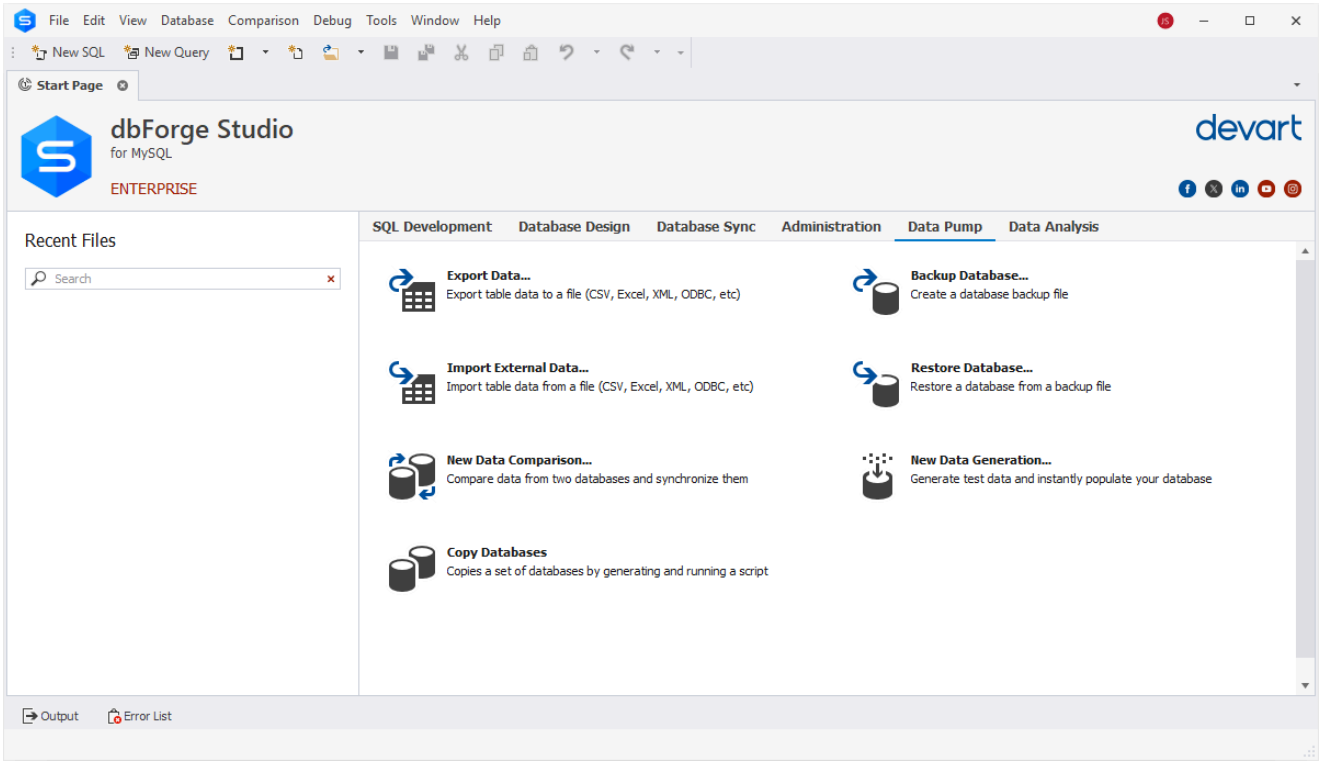
Database Compare and Sync

- Data and schema synchronization and comparison.
- Recurring database sync tasks planning.
- Comparison report generation.



Import and Export Data

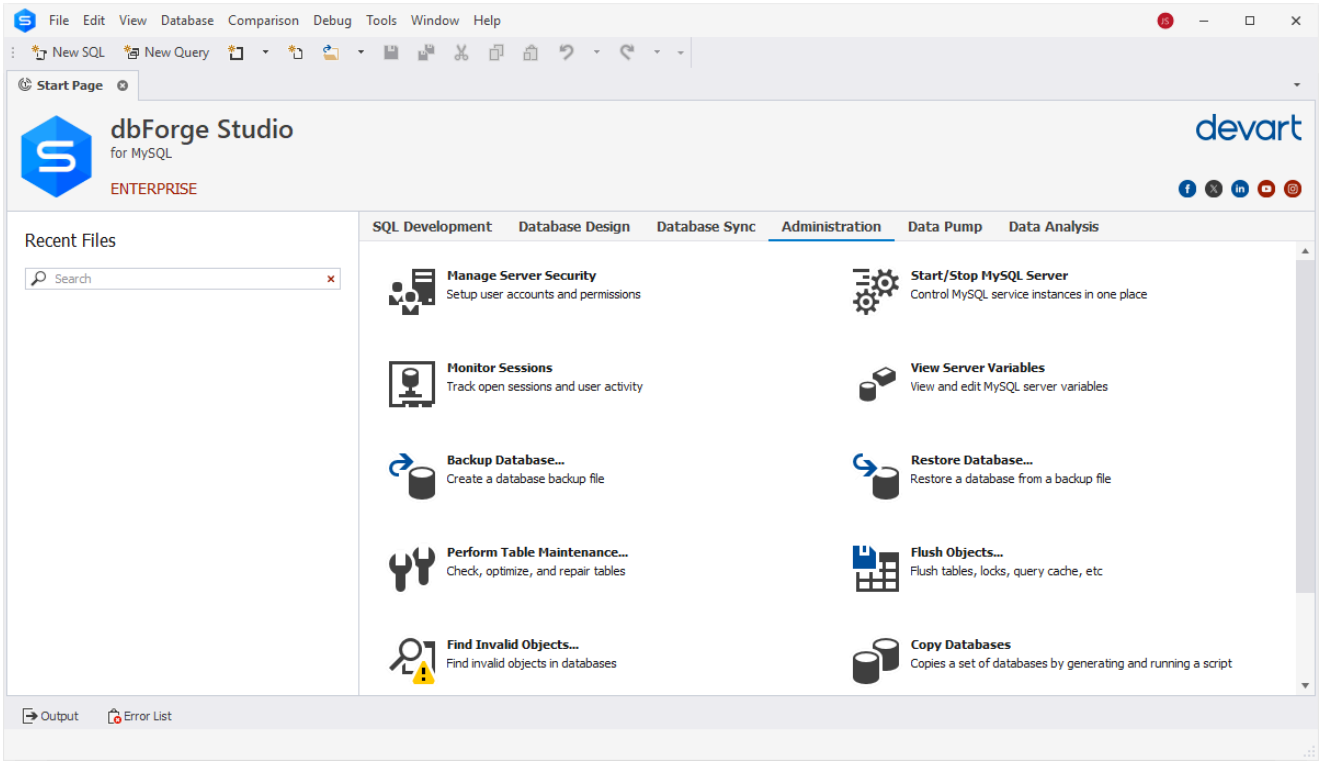
- MariaDB data export to commonly used formats.
- Data import from popular formats into MariaDB table.
- Rich customization ability.
- Command-line automation for data tasks.



MariaDB Administration Tools

- MariaDB databases backing up and restoring.

- User accounts and permissions configuration.
- Table maintenance.
- Database scripts generation.

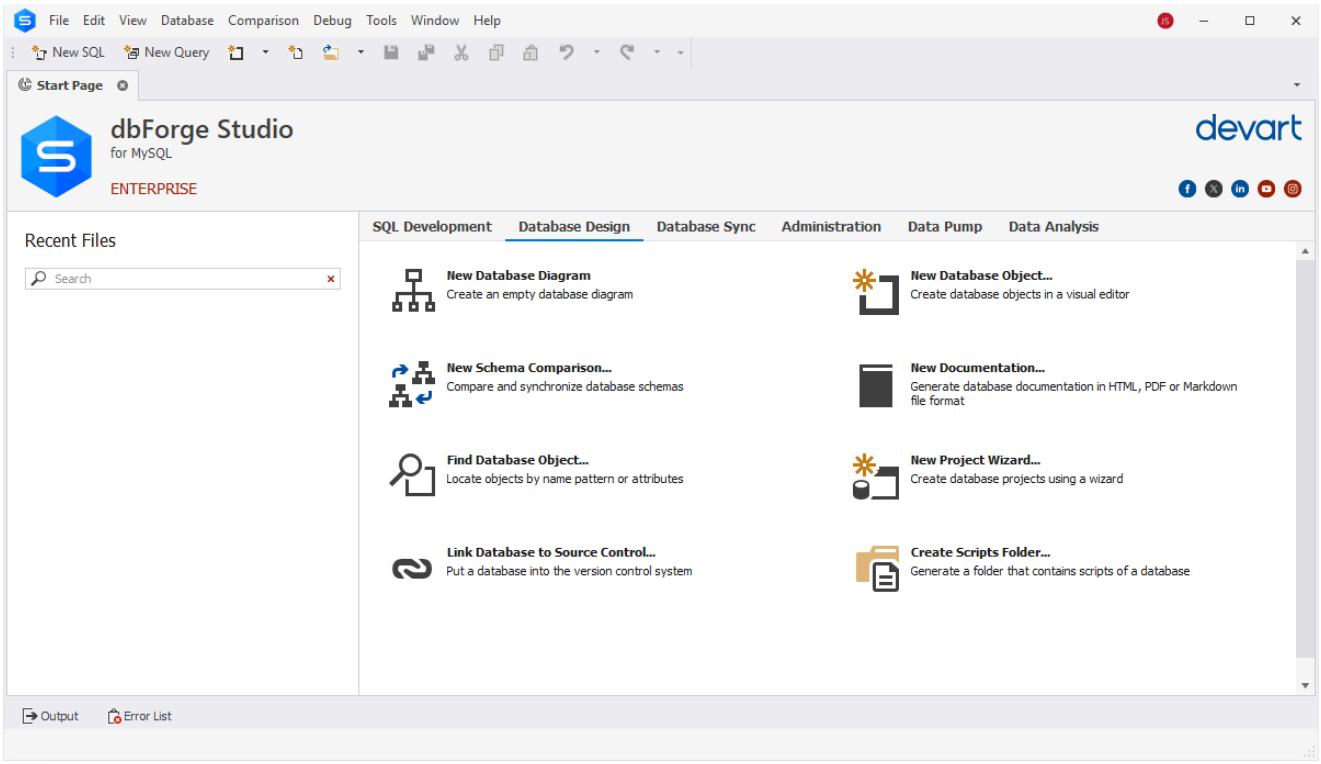


Copy Database

- Source and Target server selection.
- Database to be copied or dropped selection.
- Configuration of the database copying parameters.
- Progress of copying tracing and abortion of the copying.

Database Designer

- Schema diagrams generation.
- Visual database construction.
- Foreign key relations between tables.



Data Generator

- Data customization supported by multiple generators.
- All kinds of generators: basic, meaningful, and user-defined.
- Real-time preview of generated data.
- Command-line interface.

Query Profiler

- Visual query profiling.
- Profiling results comparison.

Visual Query Builder

- Automatic generation of the script template for queries.
- Easy navigation through the database objects.
- Support for different query types.
- Support for sequence tables.

Table Designer

- Table creation and editing in MariaDB with no code.
- Automatic data type setting for frequently-used column values.
- Errors prevention while working with tables.
- MariaDB script automatic generation according to the changes made by a user.

Database Refactoring

- Renaming database objects with preview.
- Refactoring script.

Source Control

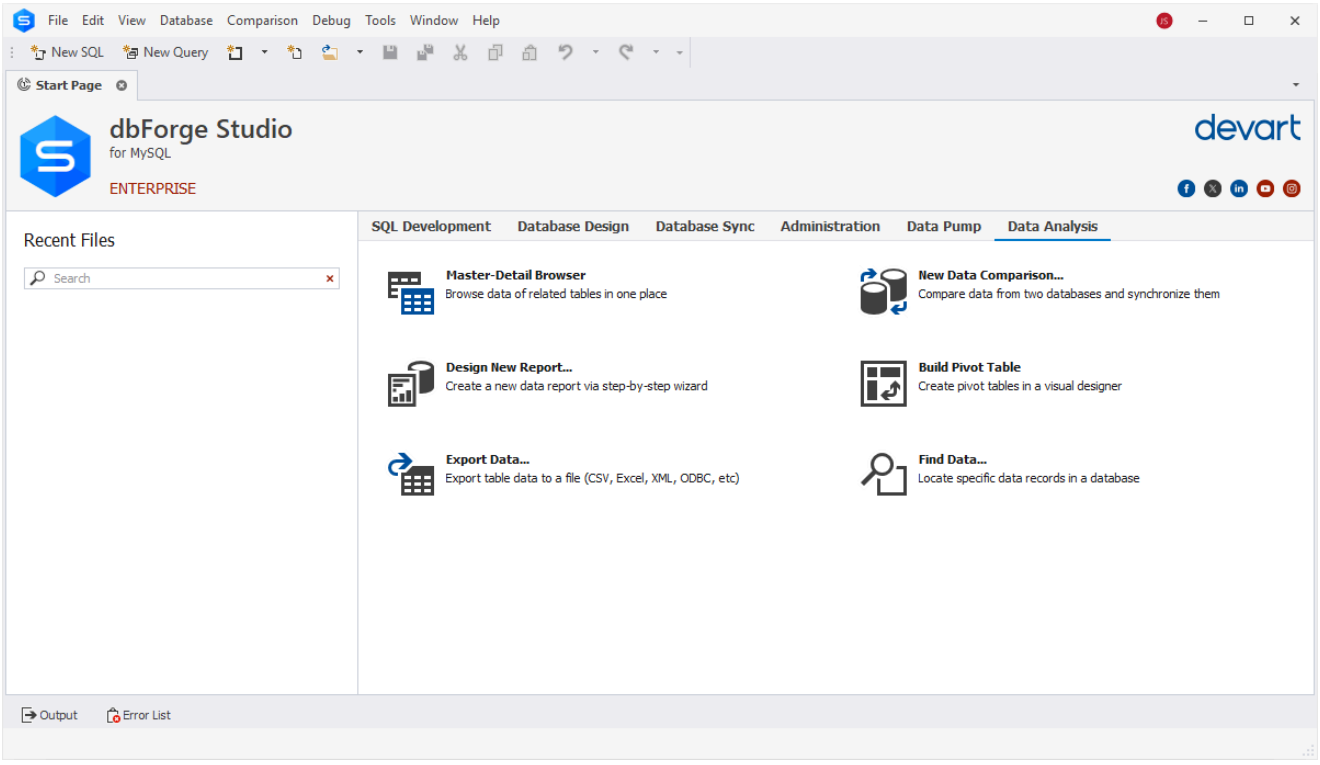
- Version control of database schemas and static table data.
- Compatibility with all major version control systems.
- Dedicated and shared development models.
- Quick comparison of database versions.
- Examination and resolution of conflicts.
- History of changes.

Database Projects

- MariaDB version control system providing efficient database team development.
- Scripts folder for exporting a database project to a MariaDB script file.

Report and Analysis

- Pivot tables for summarizing and viewing the data.
- A powerful wizard with robust features.
- Full command line support.
- 9 formats for reports' delivery.



Database Documenter

- A comprehensive overview of the database structure.
- Examine the internal dependencies between objects and databases.
- Customize the style and generate the docs in several formats.

Support for MariaDB Objects

- Packages.
- Sequences.
- Temporal tables.

This database tool is one of the most appreciated worldwide and trusted by many people. Devart's dbForge Studio has received a lot of awards that confirm its overwhelming popularity.

Download a free 30-day trial of dbForge Studio for MariaDB and MySQL here.

Documentation is available, too.

Version	Introduced
dbForge Studio for MySQL 10.1	Support for the rds-ca-rsa2048-g1 SSL/TLS certificate for connecting to MariaDB servers on AWS and enhanced cloud compatibility features, new automation capabilities.
dbForge Studio for MySQL 10.0	Support for MariaDB 11.4, added Source Control, support for temporal tables in MariaDB.
dbForge Studio for MySQL 9.2	Support for MariaDB 11.3, enhanced code completion for application-period temporal tables, support for sequence tables in MariaDB databases
dbForge Studio for MySQL 9.1	Connectivity support for MariaDB 10.9 and 10.10.
dbForge Studio for MySQL 9.0	Connectivity support for MariaDB 10.5 and 10.6.
dbForge Studio for MySQL 8.1	Support for MariaDB 10.4.

DbSchema

> **Note:**
>
> DbSchema is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

DbSchema helps you design, document and manage databases. Design new tables, generate HTML5 documentation, explore and edit the database data, compare and synchronize the schema over multiple databases, edit and execute SQL, and generate random data.

DbSchema is compatible with all relational and some No-SQL databases. It works on all major operating systems, including Windows, Linux and macOS.

You can download and evaluate DbSchema 15 days for free.

DBSchema Webpage

DbVisualizer

> **Note:**
>
> DbVisualizer is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

DbVisualizer is a cross-platform database tool for developers, DBAs, analysts and SQL programmers. Both Free and paid Pro versions are available. Supported databases include MySQL, MariaDB, and PostgreSQL.

DbVisualizer has been carefully developed by a small and dedicated team. Development decisions are based on user feedback.

Example of features:

- Simple navigation of database objects and their properties.
- Integrated AI Assistant, opt-in to ask questions, explain errors and analyze your code using a simple chat interface.
- Version control using Git, track and share database scripts, collaborate, clone, switch branches, push changes and explore history.
- Visual rendering of primary/foreign keys.
- Table data editing in spreadsheet with Export and import database schema.
- Flexible user interface in light and dark themes.
- Query optimization with an explain plan feature.
- Visual query builder using drag and drop.
- Flexible SQL scripts execution with parameter support.
- SQL formatting and Command-line interface for headless execution.
- All features.

This page is licensed: CC BY-SA / Gnu FDL

DeZign for Databases

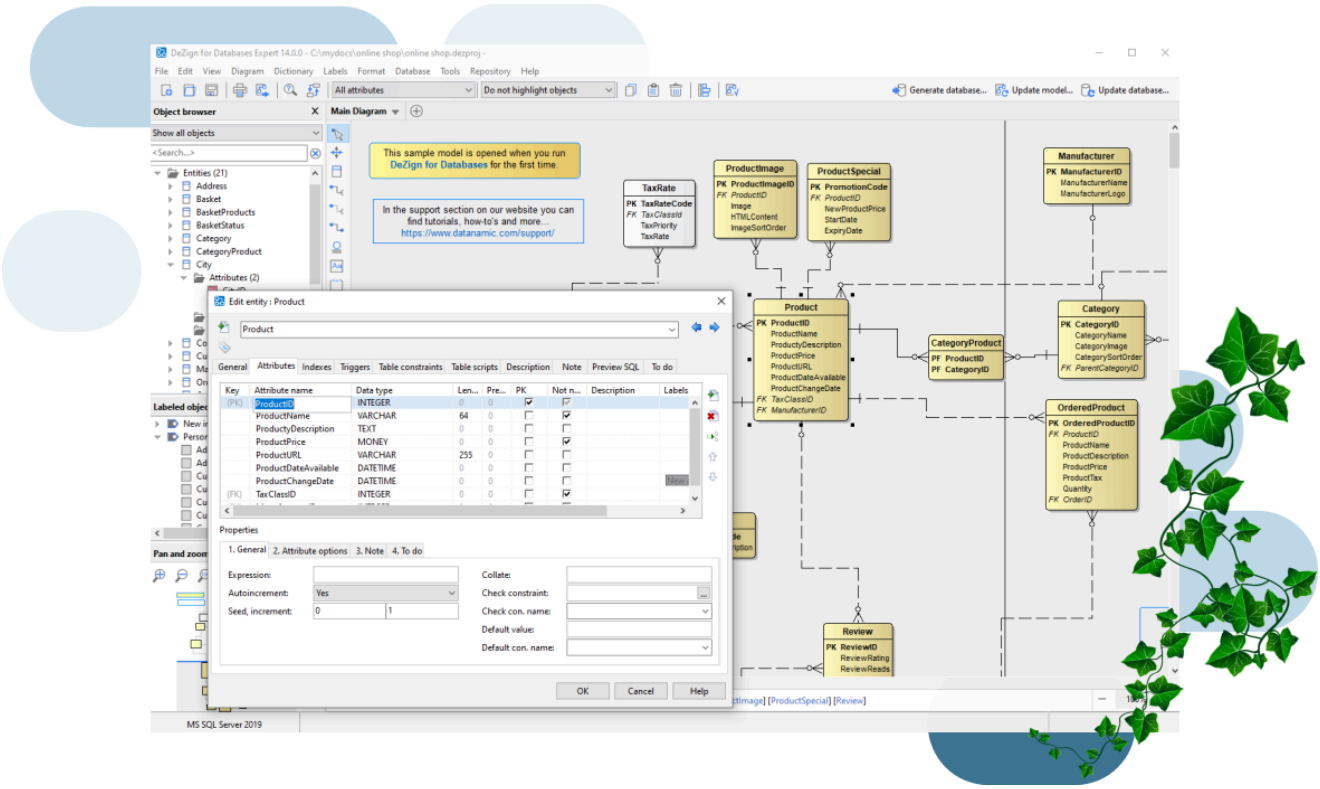
> **Note:**
>
> DeZign for Databases is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

DeZign for Databases is a data modeling tool for developers and DBA's that helps model, create, and maintain MariaDB databases. It runs on Windows only.

Supported database management systems include MariaDB, MySQL, and SQL Server.

Key features:

- Visual database modeling (Entity relationship diagrams).
- Generate database schemas directly from the data model.
- Incorporate changes from live databases into your existing models.
- Create change scripts by comparing your model with the live database structure.
- Publish and maintain data definitions to ensure consistency and accessibility.
- Convert models into SQL, streamlining database creation.
- Create clear and visually appealing ER diagrams, including sub-diagrams for complex systems.
- Support version control to manage different iterations of your model.



See www.datanamic.com for more information.

This page is licensed: CC BY-SA / Gnu FDL

ERBuilder Data Modeler

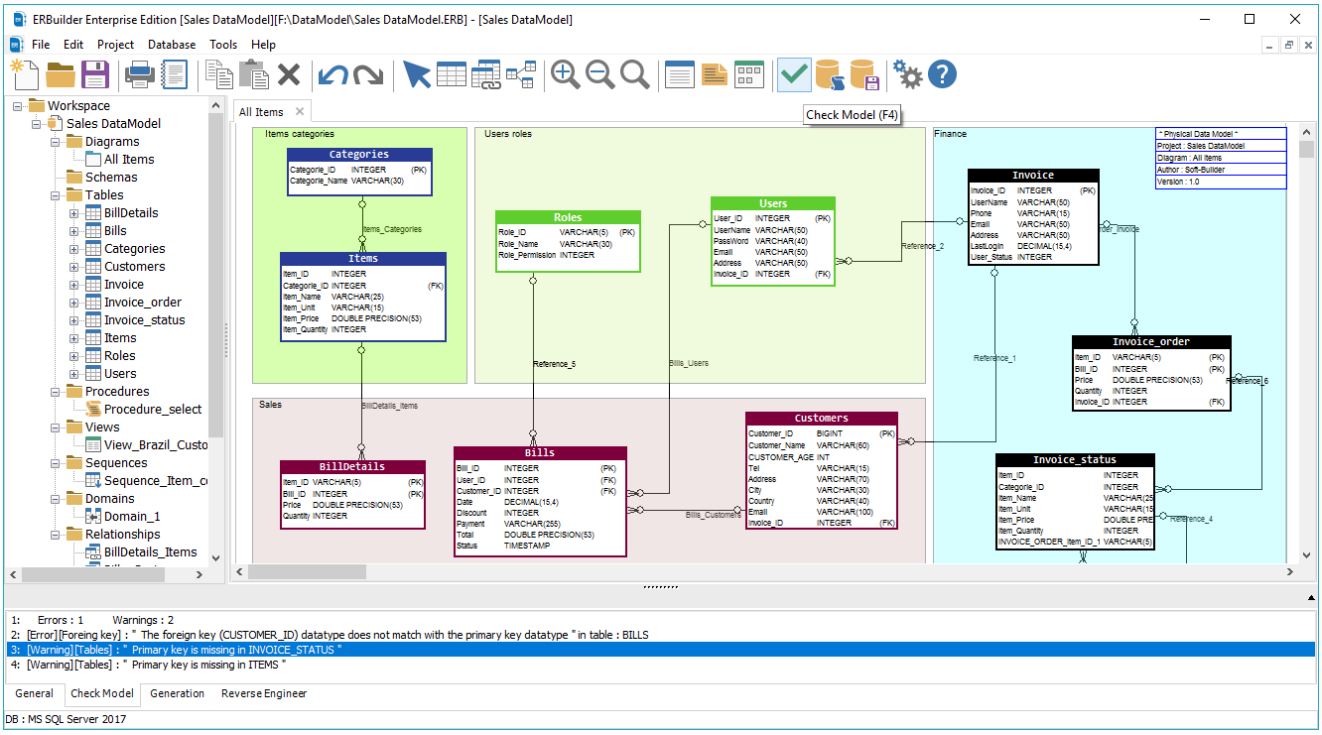
> **Note:**
>
> ERBuilder Data Modeler is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

ERBuilder Data Modeler is a GUI data modeling tool that allows developers to visualize, design, and model databases by using entity relationship diagrams and automatically generate the most popular SQL databases, and to generate and share the data model documentation. Optimize your data model by using advanced features such as test data generation, schema compare, and schema synchronization.

Supported DBMS include MariaDB, MySQL, and Microsoft SQL Server.

Key features:

- Visual data modeling.
- Forward and Reverse Engineering.
- Data Model Validation.
- Data model documentation.
- Schema Comparison and Synchronization.
- Test data generation.
- Change Database Platform.
- Generate web user interface for CRUD.
- Version management.



ERBuilder-main-screen

A feature-limited free version is available for download. Advanced features are available in the commercial edition. A feature comparison matrix is available for more details about features, pricing, and trial versions.

See www.soft-builder.com for more information.

DBeaver

> **Note:**
>
> DBeaver is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

DBeaver is a free multi-platform database tool for developers, SQL programmers, database administrators and analysts. It supports many popular relational databases like MySQL, MariaDB, and PostgreSQL.

A list of basic features:

- Data viewer and editor: sorting, filtering, image displaying, export of selected data and much more.
- Metadata browser: possibility to view and edit existing tables, views, columns, indexes, procedures, triggers, storage entities (tablespaces, partitions, etc), security entities (users, roles, etc).
- Data transfer: export and import for files in various formats (CSV, HTML, XML, XLS, XLSX).
- ER diagrams: possibility to automatically generate ER diagrams for a database/schema (diagram will contain all schema tables) or for a single table and export the diagram in a suitable format.
- SQL editor: possibility to organize all your scripts in folders, reassign database connections for particular scripts.
- Data and metadata search: full-text data search using against all chosen tables/views.
- Database structure comparing: possibility to perform objects structure compare.

Usability is the main goal of this project, so the program UI is carefully designed and implemented. Users can send bug report and feature request on the GitHub page.

OmniDB

> **Note:**
>
> OmniDB is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

OmniDB is a browser-based tool that simplifies MariaDB database management focusing on interactivity. It is designed to be powerful and lightweight.

Characteristics:

- Browser-based Tool: Accessible from any platform, using a browser as a medium.
- Responsive Interface: All available functions in a single page.
- Unified workspace: Different technologies managed in a single workspace.
- Simplified Editing: Easy to add and remove connections.
- Safety: Multi-user support with encrypted personal information.
- Interactive Tables: All functionalities use interactive tables, allowing copying and pasting in blocks.
- Smart SQL Editor: Contextual SQL code completion.
- Beautiful SQL Editor: You can choose between many available color themes.
- Tabbed SQL Editor: Easily add, rename or delete editor tabs.

Sequel Pro

> **Note:**
>
> Sequel Pro is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

Sequel Pro is a fast, database management application for working with MySQL and MariaDB databases. It runs on macOS only.

Sequel Pro is open source, so it's easy to be involved and enhance it for MariaDB.

If you have any issues with Sequel Pro on MariaDB, please use the issue tracking for that!

HeidiSQL

> **Note:**
>
> HeidiSQL is third-party software, not developed or maintained by MariaDB. It ships as an optional component of the MariaDB Windows installer, but MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

HeidiSQL is a Windows client for MariaDB and MySQL, and is bundled with the Windows version of MariaDB.

HeidiSQL Version	Introduced
HeidiSQL 12.6	MariaDB 11.3.2, MariaDB 11.2.3, MariaDB 11.1.4, MariaDB 11.0.5, MariaDB 10.11.7, MariaDB 10.6.17, MariaDB 10.5.24, MariaDB 10.4.33
HeidiSQL 12.3	MariaDB 11.0.1, MariaDB 10.11.3, MariaDB 10.10.4, MariaDB 10.9.6, MariaDB 10.8.8, MariaDB 10.6.13, MariaDB 10.5.20, MariaDB 10.4.29

HeidiSQL Version	Introduced
HeidiSQL 11.3	MariaDB 10.6.2, MariaDB 10.5.11, MariaDB 10.4.20, MariaDB 10.3.30, MariaDB 10.2.39
HeidiSQL 11.0	MariaDB 10.5.2, MariaDB 10.4.13, MariaDB 10.3.23, MariaDB 10.2.32, MariaDB 10.1.45, MariaDB 5.5.68
HeidiSQL 10.2	MariaDB 10.4.7, MariaDB 10.3.17, MariaDB 10.2.26, MariaDB 10.1.41, MariaDB 5.5.65
HeidiSQL 9.5	MariaDB 10.3.13, MariaDB 10.2.22, MariaDB 10.1.38, MariaDB 10.0.38, MariaDB 5.5.63
HeidiSQL 9.4	MariaDB 10.1.20, MariaDB 10.0.29, MariaDB 5.5.54
HeidiSQL 9.3	MariaDB 10.1.15, MariaDB 10.0.26, MariaDB 5.5.50
HeidiSQL 9.1	MariaDB 10.1.0, MariaDB 10.0.17, MariaDB 5.5.42
HeidiSQL 8.3	MariaDB 10.0.12, MariaDB 5.5.38
HeidiSQL 8.0	MariaDB 10.0.2, MariaDB 5.5.31
HeidiSQL 7.0	MariaDB 10.0.0, MariaDB 5.5.20

HeidiSQL can:

- Connect to multiple servers in one window.
- Connect to servers via command line.
- Create and edit tables, views, stored routines, triggers and scheduled events.
- Generate nice SQL-exports.
- Export from one server/database directly to another server/database.
- Manage user-privileges.
- Import text-files.
- Export table rows as CSV, HTML, XML, SQL, LaTeX and Wiki Markup.
- Browse and edit table-data using a comfortable grid.
- Bulk edit tables (move to db, change engine, collation etc.).
- Batch-insert ascii or binary files into tables.
- Write queries with customizable syntax-highlighting and code-completion.
- Pretty reformat disordered SQL.
- Monitor and kill client-processes.
- Find specific text in all tables of all databases of one server.
- Optimize and repair tables in a batch manner.

More information, including Screenshots of HeidiSQL are available at the HeidiSQL Website.

KS DB Merge Tools

> **Note:**
>
> KS DB Merge Tools is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

Overview

KS DB Merge Tools for MySQL and MariaDB is a diff & merge tool for MySQL and MariaDB, allowing to compare and sync both schema and data. It is a Freemium application - many features are exposed in the Free version (available for commercial use), some extended features are available only in the paid Standard version (in many cases can be provided at no cost for open source developers).

Product home page

Download

Use cases

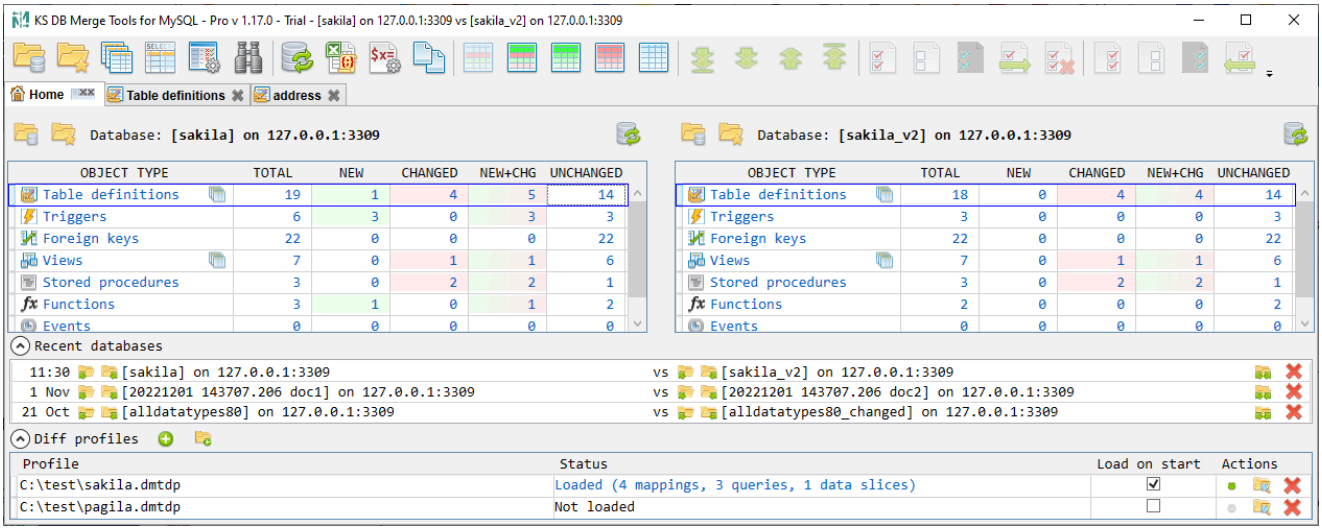
Documentation

Application has tabbed UI, there are several types of tabs responsible for particular application features and scope of tasks. Here are the primary application tabs:

Home Tab

It is a starting point to open databases. Shows summary about all database objects. Note that it does not provide information about data/content changes, only about object definitions.

This tab is also used as a starting point to manage diff profiles, making it easy to customize the tool for your specific database project. Here, you can save and reuse custom queries, mappings, and data slices, allowing you to create tailored data diff summaries.



Object List

Lists all objects of some particular type - tables, views, etc. Allows to identify whether some object is new, changed or unchanged (note that for tables and views it does not provide information about data/content changes, only about object definitions). Quick filters available to show only new/changed/new+changed objects. Here we can select required objects on one side and generate a synchronization script to merge these changes to the other side.

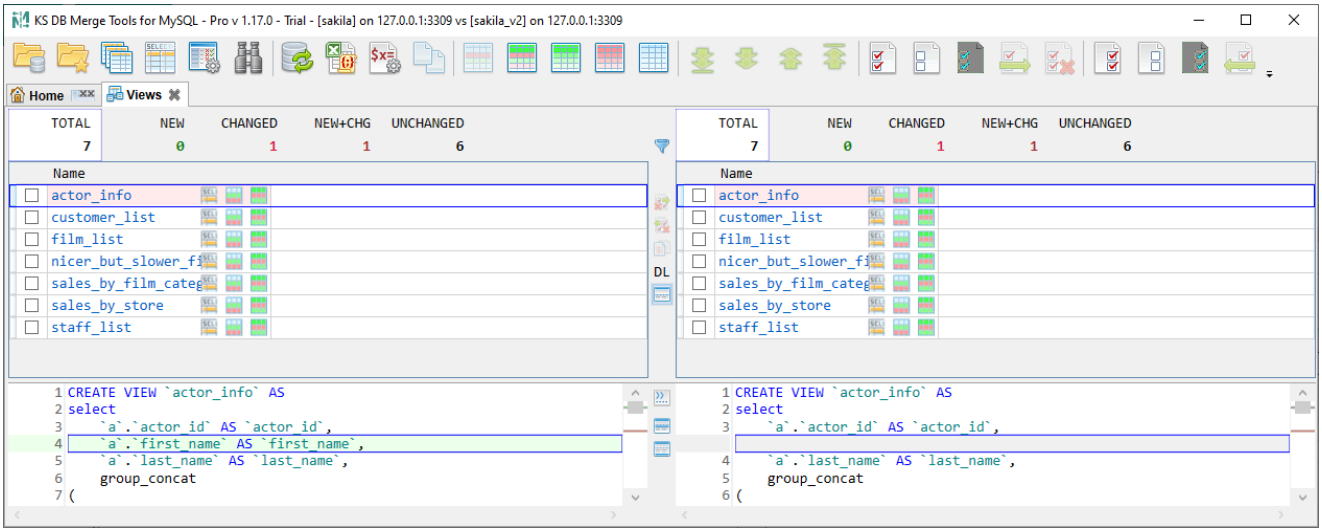


Table Data Diff

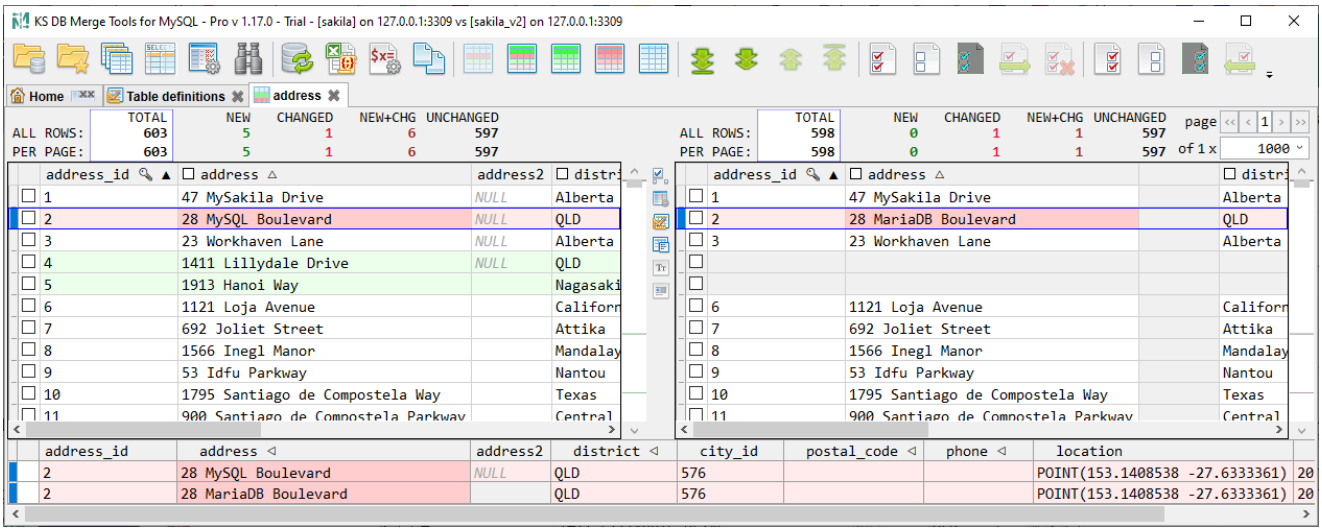
Compares data for particular table or view. Quick filters available to show only new, changed, or new and changed rows. We can select required rows on one side and generate synchronization script to merge these changes to the other side.



Text Diff

Compares definition of some particular database programming object like view or stored procedure.

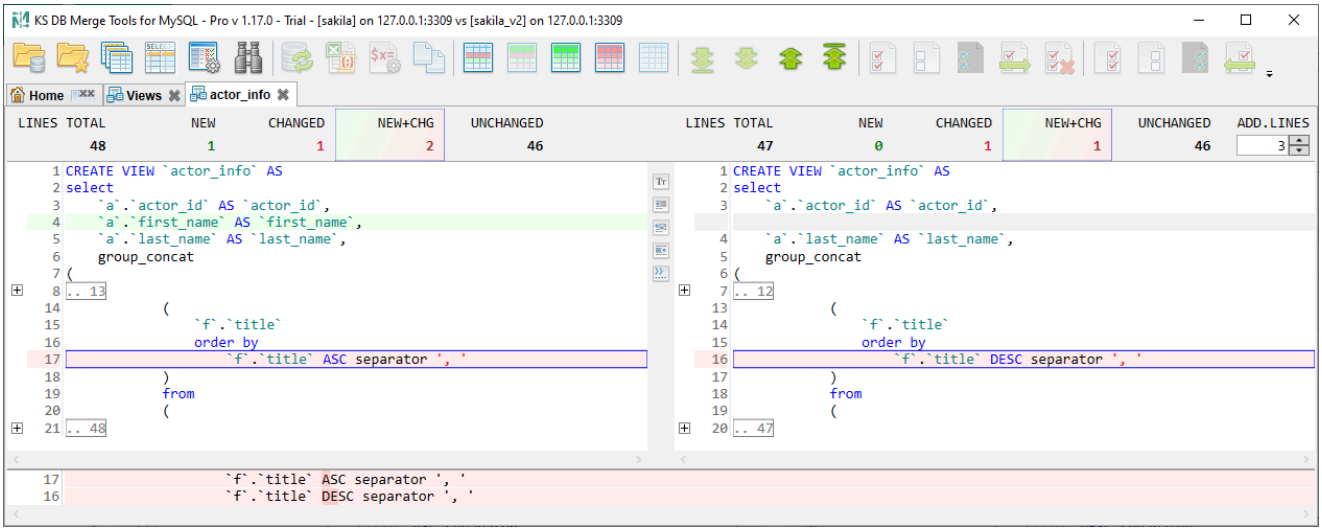


Table Structure Diff

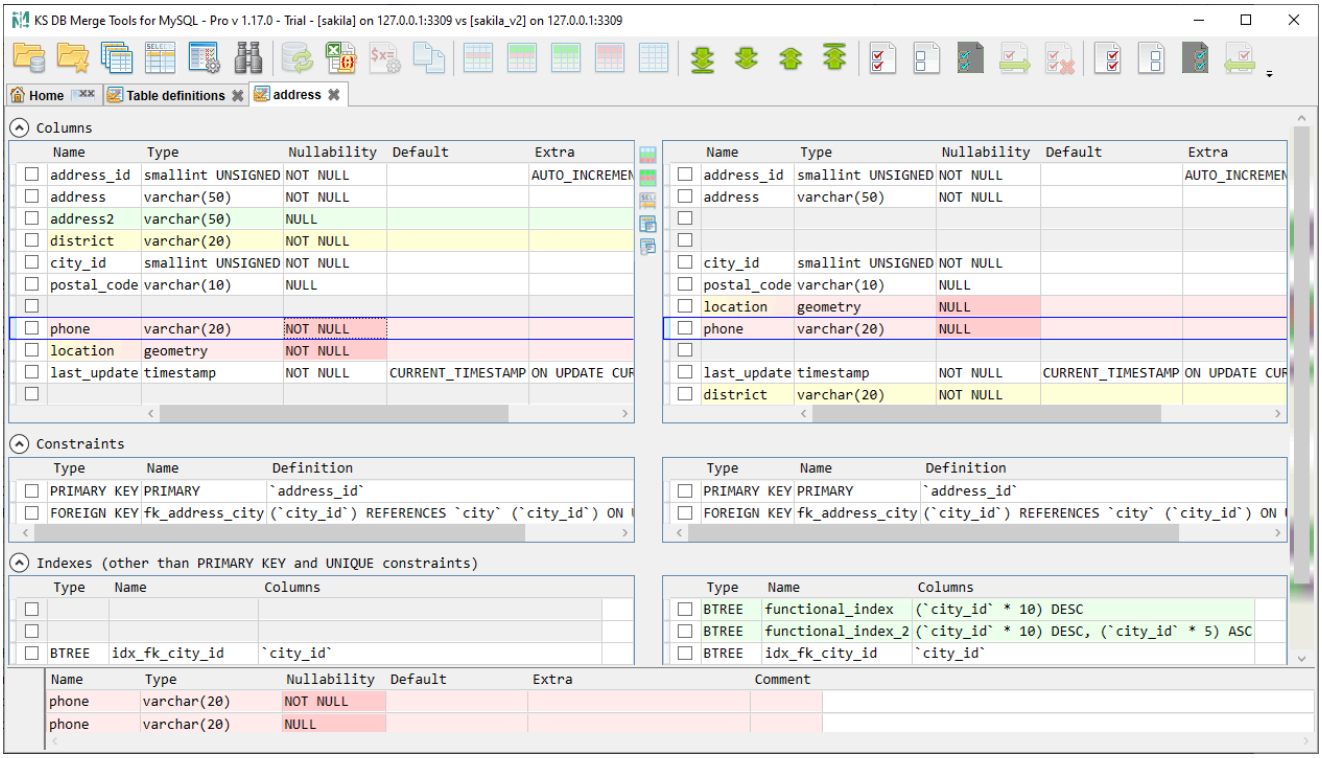
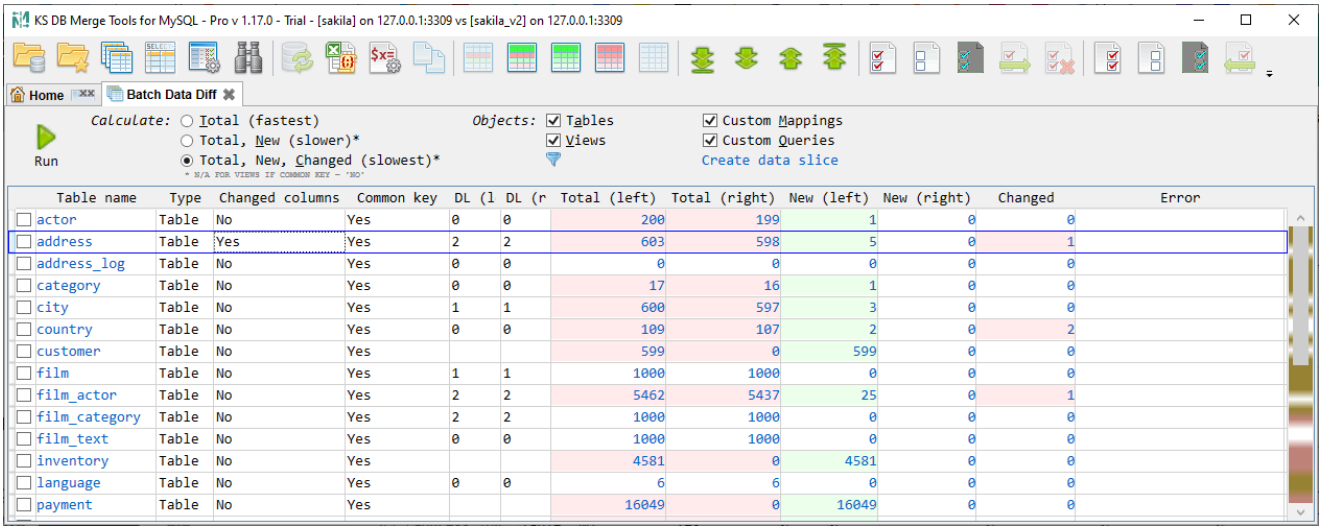
Compares definition of particular table. Here we can select required changes and generate synchronization script for them. This tab is available only in the Standard version, the Free version is using Text diff tab to compare table definitions.



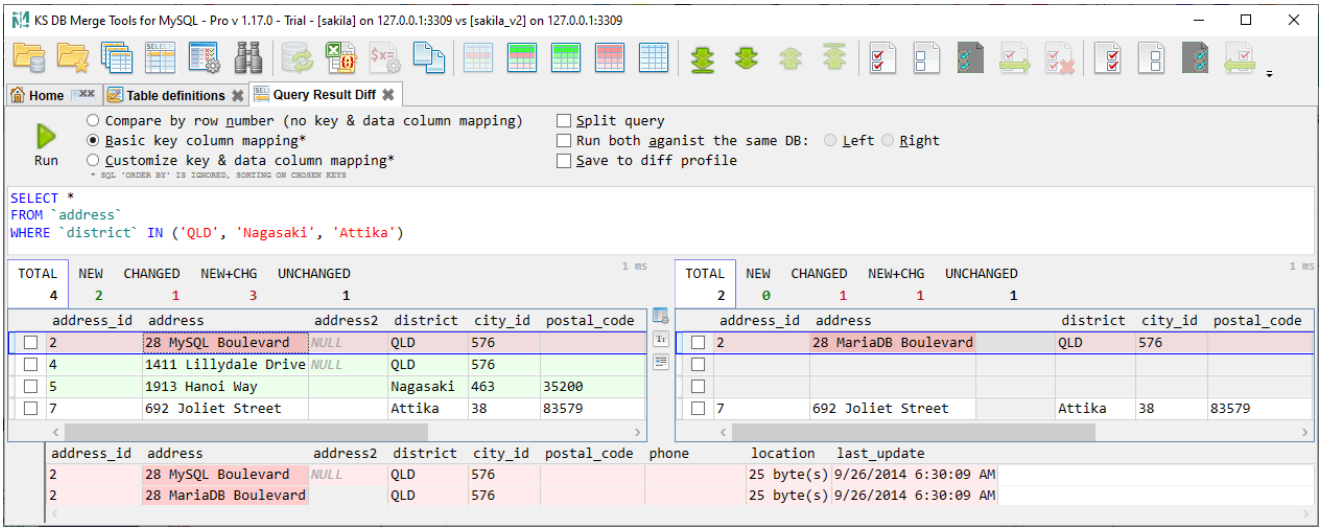
Batch Data Diff

Allows to compare data for multiple tables and views, providing summary of data changes for the whole database. This tab is available only in the Standard version.



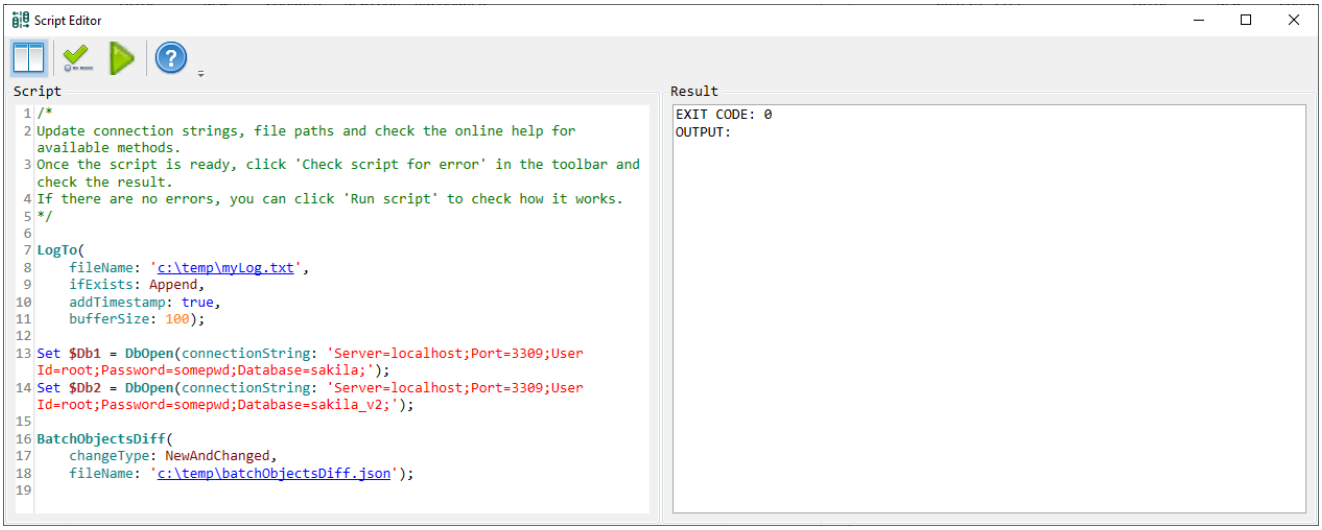
Query Result Diff

Compares arbitrary query results, it can be the same query running on both databases or different queries running on the same or different databases. This tab is available only in the Standard version.



Automation and Scripting

The Standard version has support of own domain-specific scripting language designed to automate diff and merge tasks provided by GUI. In addition to the primary GUI, there is a Script Editor application designed to help in writing and troubleshooting scripts and a separate command line utility that is used to run these scripts without user interaction. For the most typical tasks the scripts can be generated just with a single button click on GUI which produces a script relevant for the data or objects you currently observe on UI.



This page is licensed: CC BY-SA / Gnu FDL

LibreOffice Base

> **Note:**
>
> LibreOffice Base is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

LibreOffice Base is an open source RDBMS (relational database management system) frontend tool to create and manage various databases.

Preparing the ODBC Connection

First, make sure to prepare MariaDB Connector/ODBC as explained in MariaDB Connector/ODBC.

This includes

- downloading the latest MariaDB Connector/ODBC,
- copying the shared library libmaodbc.so to /usr/lib/[multi-arch],
- installing the unixodbc, unixodbc-dev, openssh-client, odbcinst packages, and
- creating a template file for the ODBC driver.
- Install the ODBC driver from the template file by running:

```
$ sudo odbcinst -i -d -f MariaDB_odbc_driver_template.ini
odbcinst: Driver installed. Usage count increased to 1.
    Target directory is /etc
```

Verify the installation was successful in `/etc/odbcinst.ini` file (this path is obtained by the config info */-j/* option, where drivers are installed in that predefined location).

```
$ odbcinst -j
unixODBC 2.3.6
DRIVERS............: /etc/odbcinst.ini
SYSTEM DATA SOURCES: /etc/odbc.ini
FILE DATA SOURCES..: /etc/ODBCDataSources
USER DATA SOURCES..: /home/anel/.odbc.ini
SQLULEN Size.......: 8
SQLLEN Size........: 8
SQLSETPOSIROW Size.: 8

$ cat /etc/odbcinst.ini
[MariaDB ODBC 3.1 Driver]
Description=MariaDB Connector/ODBC v.3.1
Driver=/usr/lib/x86_64-linux-gnu/libmaodbc.so
UsageCount=1
```

- Create a template file for the Data Source Name (DSN). A sample “MariaDB_odbc_data_source_template.ini” could be:

[MariaDB-server]
Description=MariaDB server
Driver=MariaDB ODBC 3.1 Driver
SERVER=localhost
USER=anel
PASSWORD=
DATABASE=test
PORT=3306

- Install data source:

```
odbcinst -i -s -h -f MariaDB_odbc_data_source_template.ini
```

- Verify successful installation in the /.odbc.ini file

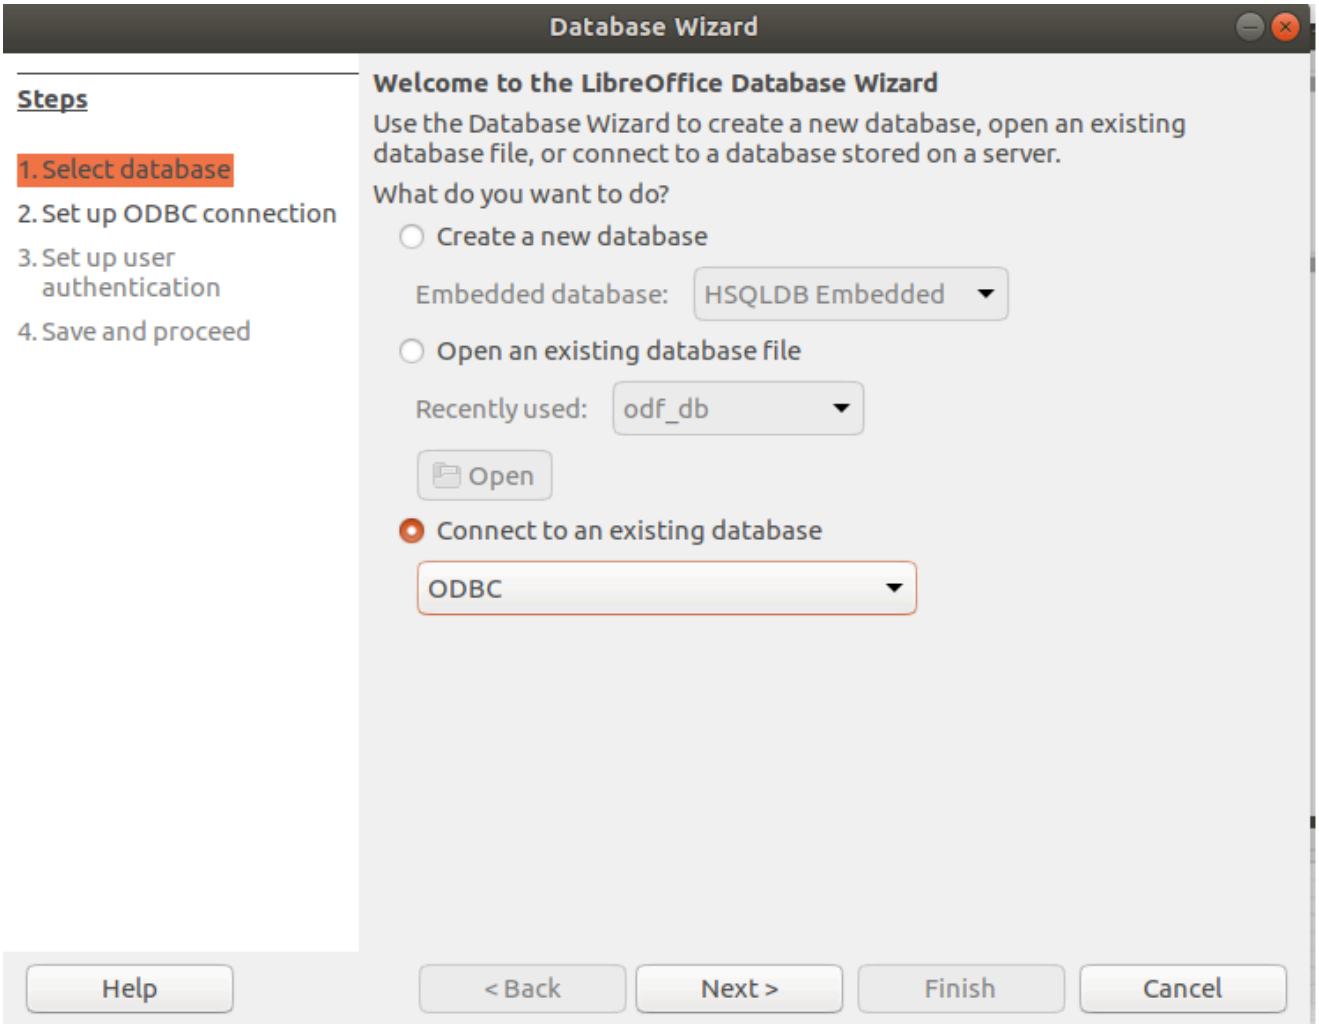
```
$ cat ~/.odbc.ini
[MariaDB-server]
Description=MariaDB server
Driver=MariaDB ODBC 3.1 Driver
SERVER=MariaDB
USER=anel
PASSWORD=
DATABASE=test
PORT=3306
```

- Verify successful installation also using the isql utility:

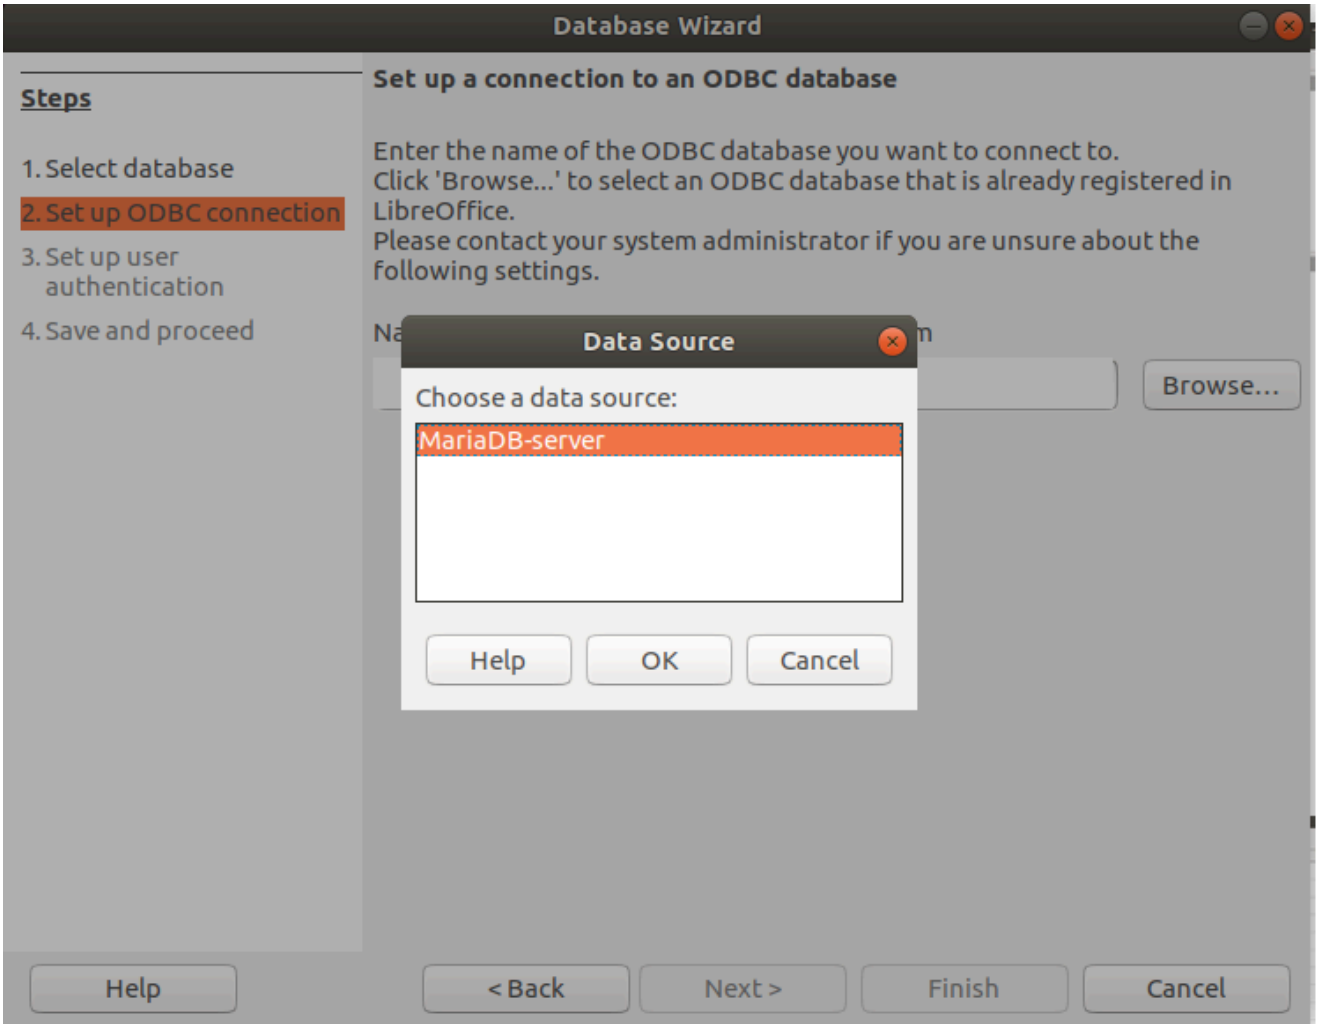
```
$ isql MariaDB-server
+---------------------------------------+
| Connected!                            |
|                                       |
| sql-statement                         |
| help [tablename]                      |
| quit                                  |
|                                       |
+---------------------------------------+
SQL> show tables;
+---------------------------------------------------------------------------+
| Tables_in_test                                                            |
+---------------------------------------------------------------------------+
| Authors                                                                   |
| tbl_names                                                                 |
| webposts                                                                  |
| webusers                                                                  |
+---------------------------------------------------------------------------+
SQLRowCount returns 4
4 rows fetched
```

Start with LibreOffice Base

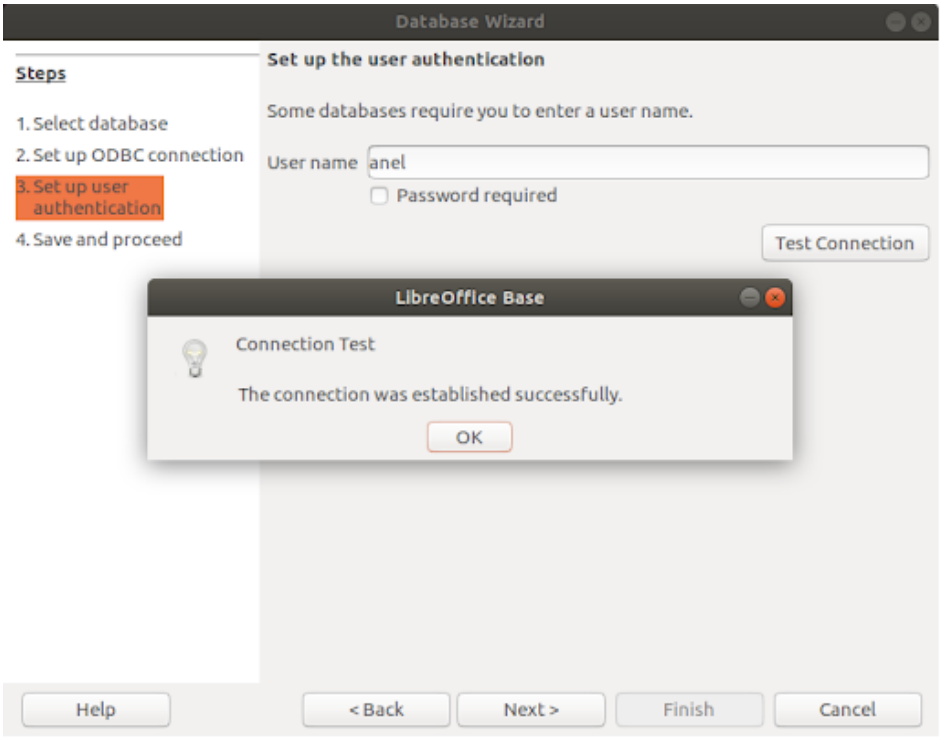
Start Libreoffice Base from the terminal by running *lobase* (make sure to install the *libreoffice-base* package if needed). The default option is to create a new database, which is *HSQLDB*. In order to connect to a running MariaDB server, choose *“Connect to an existing database”* and choose *“ODBC”* driver as shown below:



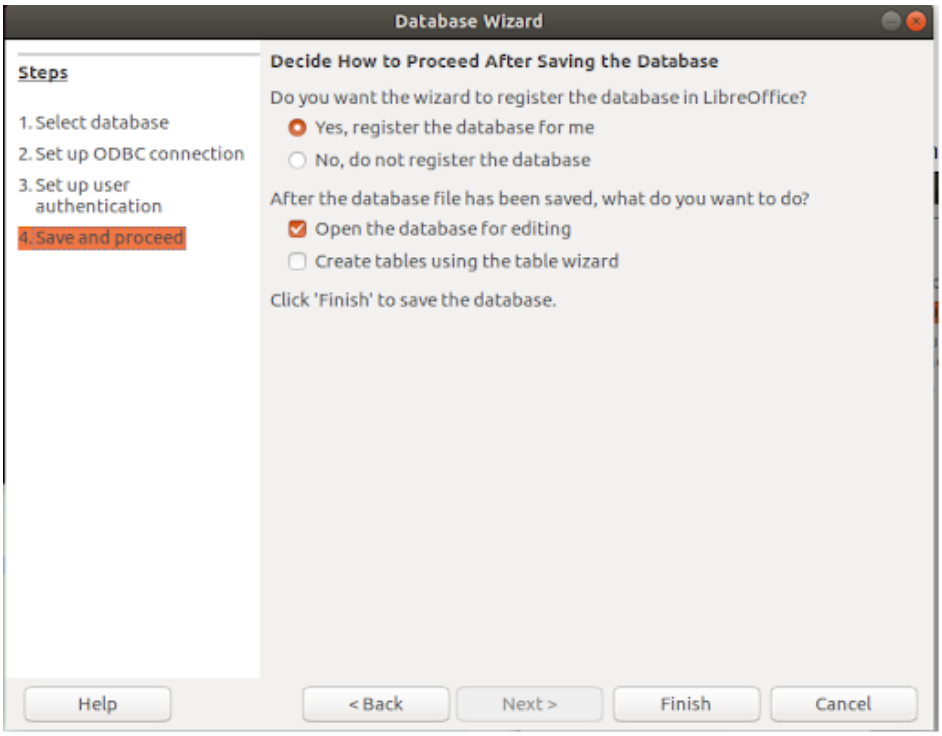
After that, choose DSN (the one that we created in the previous step) and click *“Next”*:



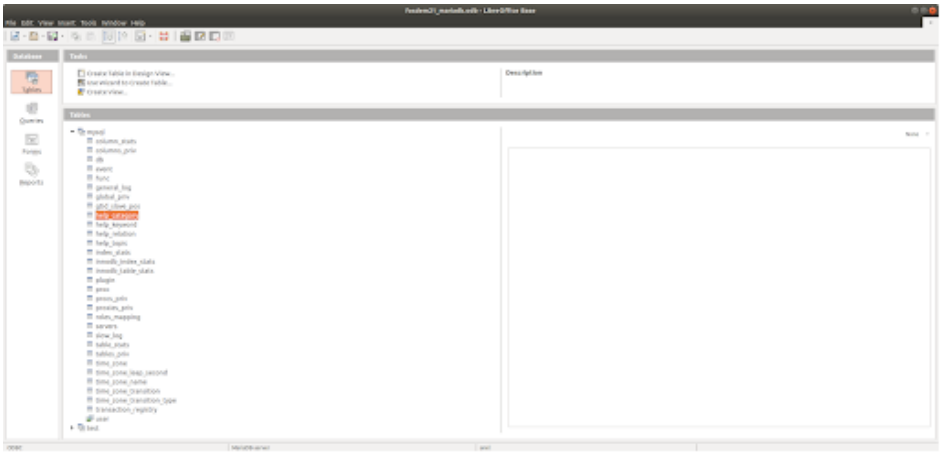
Provide a user name (and password if needed) and again check the connection (with the *"Test Connection"* button) and click *"Next"*:



After that, we have options to register the database. Registration in this sense means that the database is viewable by other LibreOffice modules (like *LibreOffice Calc* and *LibreOffice Writer*). So this step is optional. In this example, we will save as *"fosdem21_mariadb.odb"*. See Using a Registered Database.



It opens the following window:



It consists of three panels:

1. "Database" window with the options,
2. "Tables",
3. "Queries",
4. "Forms",
5. "Reports".
6. "Tasks window (dependent on what is selected in the "Database" window). When "Tables" is selected, the options are:
7. "Create Table in Design View",
8. "Use Wizard to Create Table" and
9. "Create View".

10. “Tables” window - shows list of tables that are created.

As we can see, there are system tables in the *“mysql”* database as well as *“test”* database.

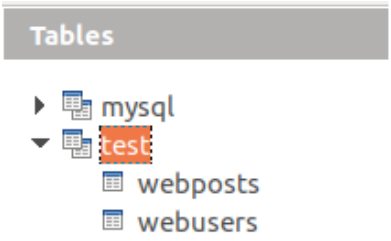
Let’s say we create a table using the REST API from JSON data from posts, and another table using the same mechanism from users, and let’s call them *webposts* and *webusers*. In order to do so, we have to enable the **CONNECT** storage engine plugin and start with REST_API. See more in the CONNECT - Files Retrieved Using Rest Queries article.

The queries we need to run in MariaDB are:

```
CREATE TABLE webusers ENGINE=CONNECT TABLE_TYPE=JSON
  HTTP='http://jsonplaceholder.typicode.com/users';

CREATE TABLE webposts ENGINE=CONNECT TABLE_TYPE=JSON
  HTTP='http://jsonplaceholder.typicode.com/posts';
```

The result in LibreOffice Base is as shown below:



librebase_6

Double clicking on the table opens a new window with the data displayed to inspect:

id	name	username	email	address	phone	website	company
1	Leanne Graham	Bret	Sincere@april.biz	Kulas Light Apt. 556 Gwenborough	1-770-736-8031 x56442	hildegard.org	Romaguera-Crona Multi-layered clien

10	Clementina DuBuque	Moriah.Stanton	Rey.Padberg@karina.biz	Kattie Turnpike Suite 198 Lebsackbu	024-648-3804	ambrose.net	Hoeger LLC Centralized empowering

To create the table from the *“Tasks”* window, use the option *“Create Table in Design View”*, where one can specify specific field names and types as shown:

From the “Tasks” window one can create a table using the option *“Use Wizard to Create Table”* to create some sample tables.

One can fill the data in the existing table, or create and define the new table from the *LibreOffice Calc* module with simple copy-paste (in the *“Tasks”* window).

Using a Registered Database

Other modules can use the registered database, for example, open *“LibreOffice Calc”* and go to *“Tools”*, *“Options”* and you will see the *“odb”* file we registered when starting *“LibreOffice Base”*.

Luna Modeler

> **Note:**
>
> Luna Modeler is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn’t test, validate, or support it. Refer to its own documentation and license terms.

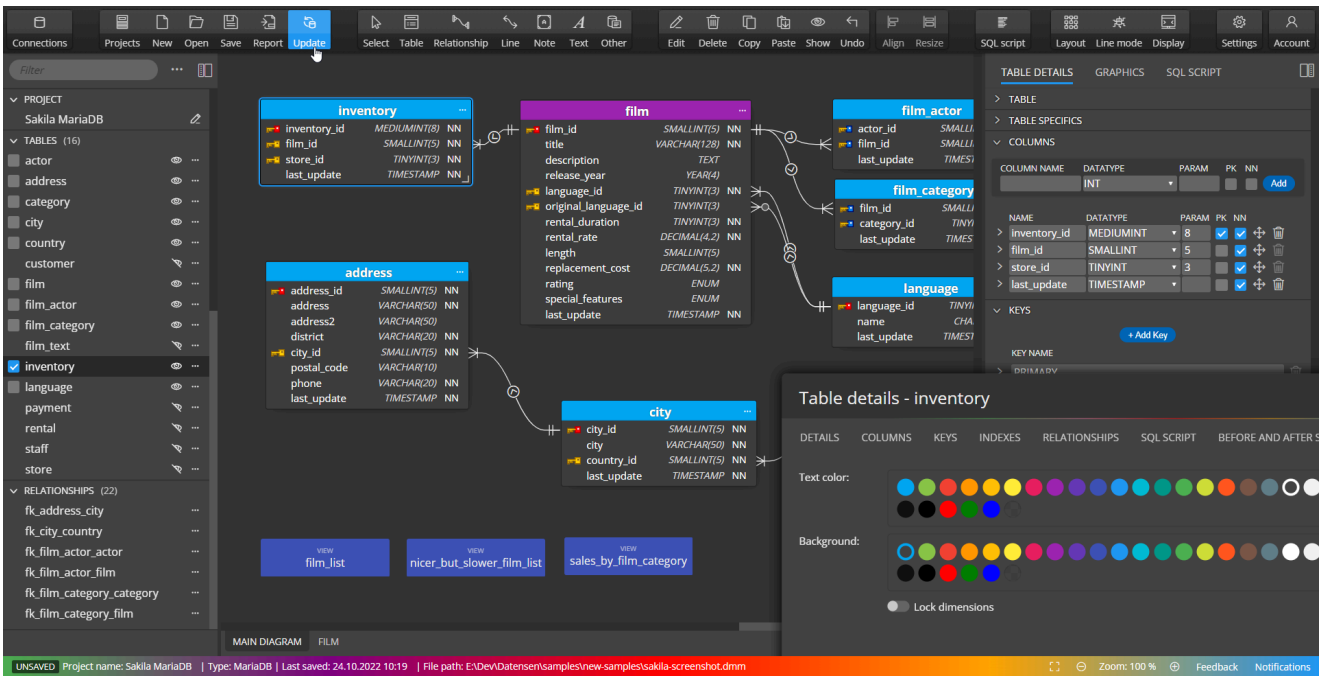
Luna Modeler is a database design tool for MariaDB and other relational databases.

Draw diagrams, reverse engineer existing database structures and generate SQL code.

Supported platforms include MariaDB, PostgreSQL, and SQLite.

Key features:

- Database modeling & schema design.
- Reverse engineering.
- Support for database-specific settings.
- Three display modes: metadata, sample data or descriptions.
- Default values for newly created objects.
- Export to PDF.
- Dark and Light themes.
- SQL script generation.



Supported OS

Luna Modeler is available for Windows, Linux and macOS.

More information

See www.datensen.com for more information.

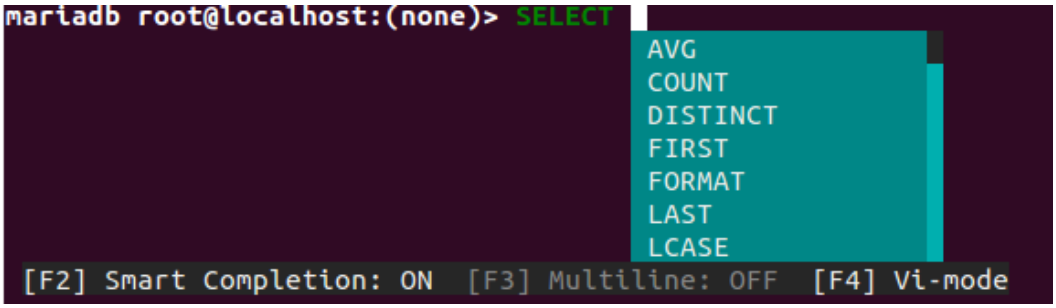
mycli

> **Note:**
>
> mycli is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

mycli is a command-line interface for MariaDB, MySQL, and Percona, with auto-completion and syntax highlighting. It is written in Python, and runs on Linux, Mac and Windows.



Read more at mycli.net.

Navicat

> **Note:**
>
> Navicat is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

Navicat is a graphical frontend for MariaDB. It is a commercial product with several different versions (Navicat Premium, Navicat for MySQL, etc…) and different "editions" within those versions (Non-commercial, Standard, and Enterprise). Certain features are only available in certain editions/versions.

Navicat is available for Windows, MacOS, and Linux.

In addition to standard client features, it includes

- An SQL Builder/Editor,
- A Data Modeling Tool (Enterprise version only),
- Data/Structure Synchronization,
- Report Builder (Windows-only),
- "Premium" version which can connect to MariaDB, MySQL, SQL Server, SQLite, Oracle, and PostgreSQL databases simultaneously.

A feature comparison matrix is available. More information, including pricing and trial versions, is available on the Navicat website.

ocelotgui

> **Note:**
>
> ocelotgui is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

The Ocelot GUI (ocelotgui), a database client, allows to connect to a MySQL or MariaDB server, enter SQL statements, and receive results. Features include syntax highlighting, user-settable colors and fonts for each part of the screen, resultset displays with multiline rows and resizable columns, and a debugger.

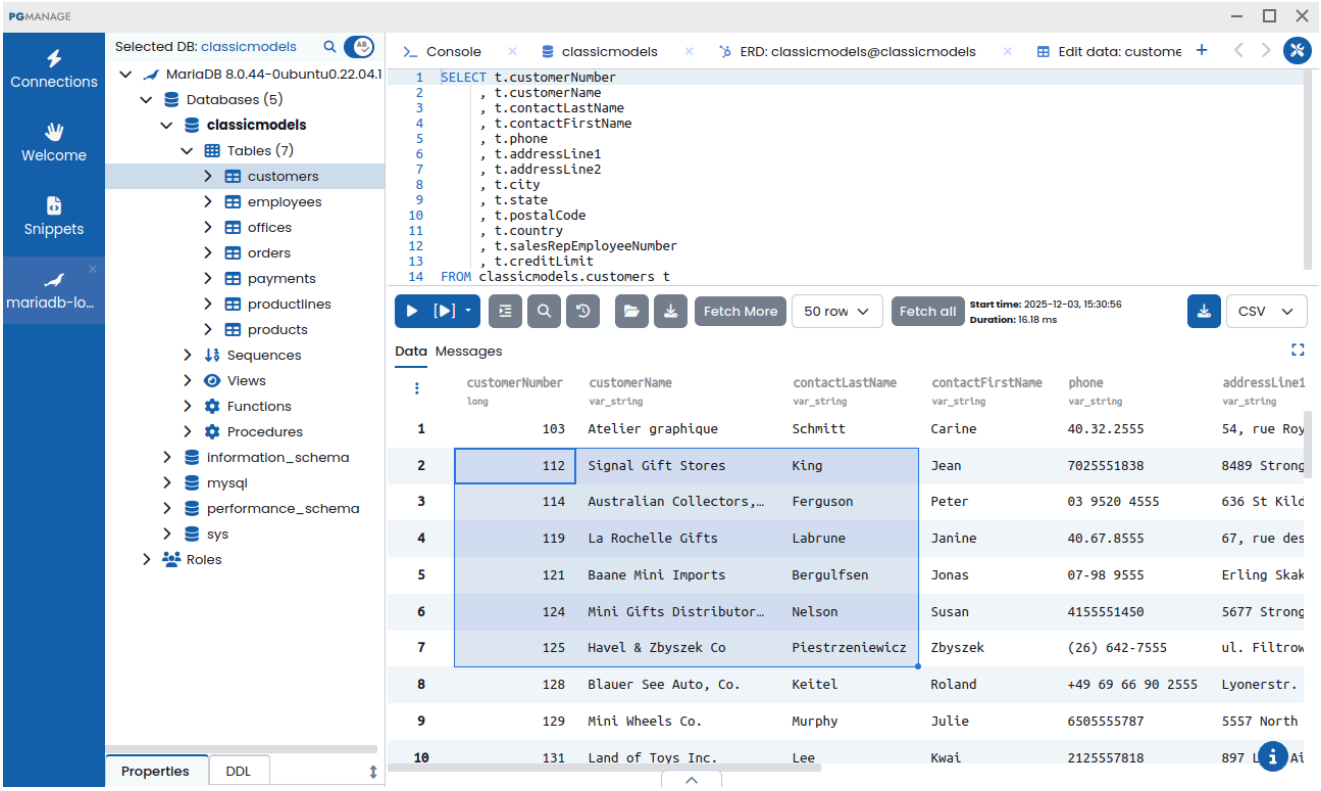
Visit ocelot.ca for more information and to download.

This page is licensed: CC BY-SA / Gnu FDL

PgManage

> **Note:**
>
> PgManage is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

PgManage is a modern SQL editor database management toolkit.



App Screenshot

PgManage supports MariaDB along many other databases.

Features:

Desktop or Browser-based: Runs as desktop application or can be installed as a webapp and used in a browser.

Modern Interface: The UI is optimized to be easy to use efficient to navigate.

Multiple Workspaces: Work with many database sessions at once and easily switch between them

Secure: Sensitive information like DB passwords, SSH keys etc. is stored in an encrypted form and protected by Master Password.

Schema and Table Editors: Create/alter tables and manage data using intuitive and clean UI.

Smart SQL Editor: Context-aware code completion, error annotations, powerful search and replace.

Light or Dark: Different themes to choose from.

Tabbed Workspace: Keep multiple editors and other tools open and easily switch between them.

Quick Search: Easily find an object in DB Explorer using a fuzzy search dialog.

Tunneling: Connect to your databases via SSH tunnel if it is not directly accessible.

phpMyAdmin

> **Note:**
>
> phpMyAdmin is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

phpMyAdmin is a web-based tool for administering MariaDB and MySQL.

It requires a web server, PHP, and a browser.

Read more at phpmyadmin.net.

This page is licensed: CC BY-SA / Gnu FDL

Querious

> **Note:**
>
> Querious is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

Querious is a database administration tool for macOS.

It can be purchased and downloaded at querious.

This page is licensed: CC BY-SA / Gnu FDL

SB Data Generator

> **Note:**
>
> SB Data Generator is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

Generate and populate databases with large volumes of realistic test data.

SB Data Generator is a simple and powerful GUI tool for creating large volumes of realistic test data to populate selected tables or entire databases. The tool reverses your database and displays tables and columns, so you can

assign to them multiple data generator templates. It includes multiple built-in generators that allow populating MariaDB database tables with realistic data of various types.

Key Benefits:

- Understand your database structure by visualizing the ER Diagram (tables, columns, relationships, keys, sequences, indexes, and triggers).
- Ability to generate a large volume of realistic test data.
- Preview what data is generated before populating the database with test data.
- Multiple built-in generators available with the ability to create custom data generators.
- Generate test data for most popular DBMS including MariaDB and MySQL.

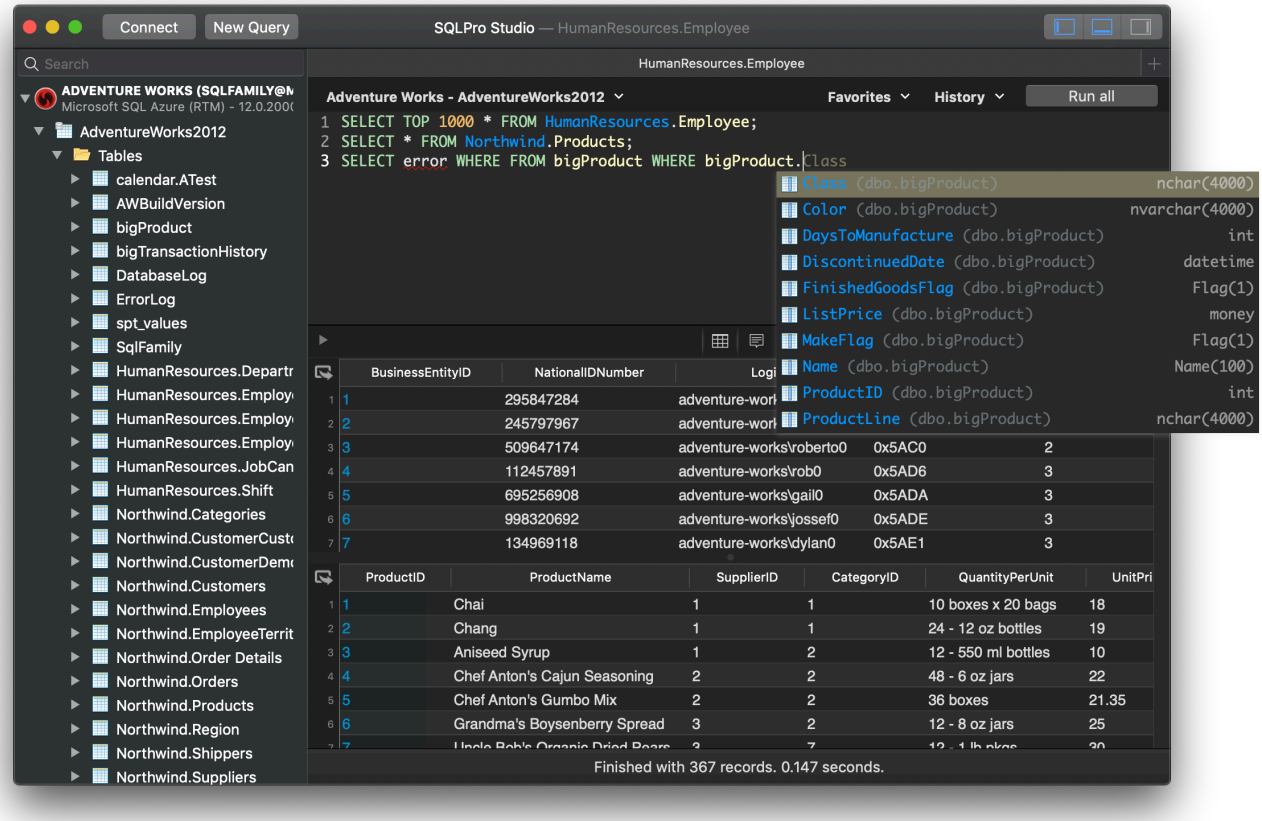
Learn more about SB Data Generator.

This page is licensed: CC BY-SA / Gnu FDL

SQLPro Studio

> **Note:**
>
> SQLPro Studio is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

SQLPro Studio is a fully native database client for macOS macOS and iOS. It supports database management systems such as MariaDB, MySQL, and Postgres.



SQLPro UI

Features include:

- Syntax highlighting & Autocomplete (sometimes called intellisense).
- Customizable themes allowing the query editor to be completely customized.
- The ability to run multiple queries at one time (and a customizable run query shortcut).
- Improved query error detection (errors in queries is underlined red).
- Full dark mode & light mode support, along with custom themes.

Other features include:

- Complete SSH Tunnel support.
- Inline data filtering.
- Exporting & Exporting options to CSV, JSON & XML.

This page is licensed: CC BY-SA / Gnu FDL

SQLyog

> **Note:**
>
> SQLyog is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

SQLyog is a GUI tool to manage MySQL and MariaDB servers and databases in physical, virtual, and cloud environments. DBAs, developers, and database architects alike, use SQLyog to visually compare, optimize, and document schemas.

Key Features:

- Automatically synchronize data,
- Visually compare data, and
- Import external data.

Additional Highlights:

- Runs on Microsoft Windows with no dependencies on runtimes (such as Microsoft .NET and Java) and database abstraction layers (such as ODBC and JDBC).
- Distributed as a free Community edition and as a paid, proprietary Ultimate edition.

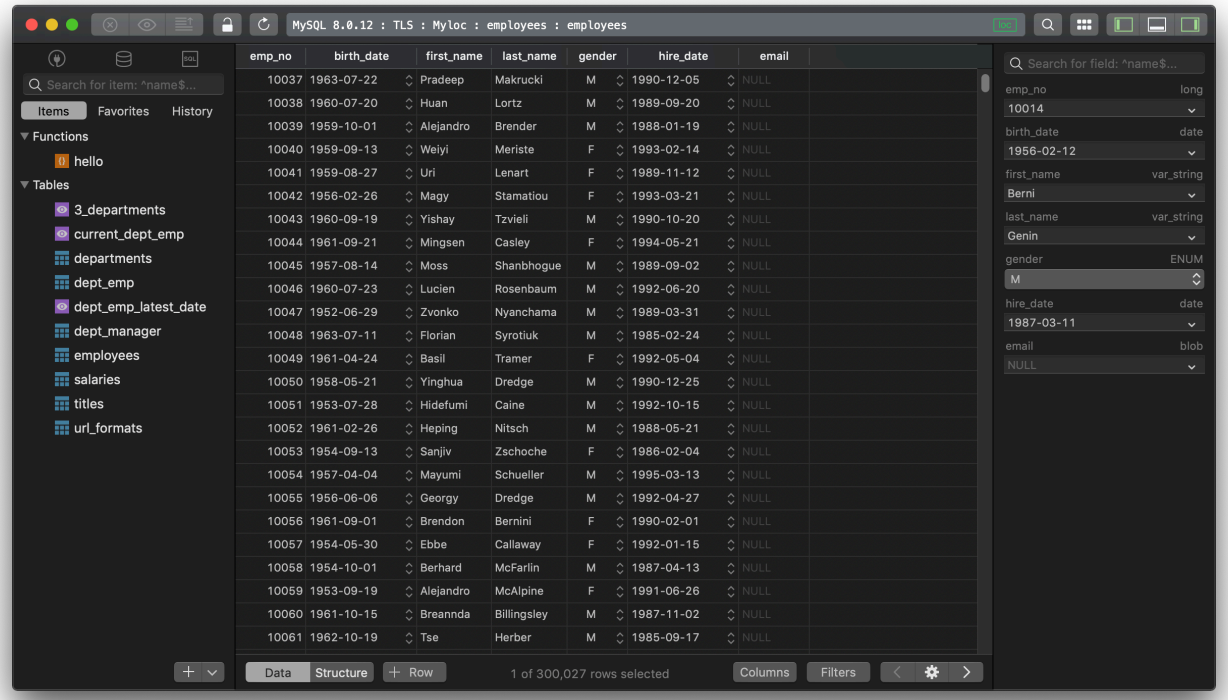
More information can be found here.

This page is licensed: CC BY-SA / Gnu FDL

TablePlus

> **Note:**
>
> TablePlus is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

TablePlus is an application with a clean user interface that allows developers to simultaneously manage databases in a very fast and secure way. It supports many popular database management systems like MariaDB, MySQL, and Postgres.



TablePlus is available for macOS, Windows, iOS, and Linux.

Some notable features:

- Native build.
- Convenient query editor.
- Multi Tabs & Code Review.
- Can connect to multiples databases simultaneously.

TablePlus is available for free, but users can purchase a license to remove some limitations and customize the tool for higher needs on TablePlus website.

This page is licensed: CC BY-SA / Gnu FDL

TOAD Edge

> **Note:**
>
> Toad Edge is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

Toad Edge is a database management application that allows you to perform database administration tasks with ease.

Toad Edge allows you to:

- Connect to your MySQL database, view, explore and edit database structure, database objects and properties.
- Manage database objects, easily add, edit or drop objects in Object Explorer.
- Manage data stored in your database, add, edit or remove records.
- Write complex SQL code comfortably in Worksheet.
- Compare and synchronize databases using powerful Schema Compare.
- Obtain detailed information about your databases.

More information can be found here.

This page is licensed: CC BY-SA / Gnu FDL

Valentina Studio

> **Note:**
>
> Valentina Studio is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

Valentina Studio is a graphical front end for MariaDB with a free version, and a Pro version that adds advanced features.

Free Valentina Studio offers the following features:

- natively available on macOS, Windows & Linux,
- a feature rich, visual SQL Editor with powerful search functionality,
- SQLDIFF,
- a highly productive Data Editor,
- support for many data sources,
- ODBC import,
- Schema Editor with powerful visual diagramming features, Diagram Editor; import diagrams from MySQL Workbench,
- Report Viewer with printing, export to PDF and HTML (local reports and from Valentina Server),
- Forms Client for working with visual forms and MariaDB (locally and from Valentina Server),
- Free supports most popular data sources, MariaDB, MySQL, SQL Server, SQLite, PostgreSQL and more.

Use the Valentina Studio FREE vs Valentina Studio PRO feature matrix to see which version is best for your needs or download to immediately evaluate.

MariaDB Direct Query Adapter For Microsoft Power BI

MariaDB Direct Query Adapter for Power BI enables Microsoft Power BI Desktop users to remotely connect to and query their MariaDB database including on MariaDB Cloud without downloading the entire data set to their local machine.

MariaDB Direct Query Adapter is a Microsoft certified connector for Microsoft Power BI Desktop.

About

Microsoft Power BI Desktop is a free business intelligence tool available as a downloadable desktop client. Built for analysts, Microsoft Power BI provides state-of-the-art interactive visualizations, with industry-leading data query and modeling built-in. It is one of the top business intelligence tools in use globally.

MariaDB database products support analytics and data warehousing in addition to transactional databases. Customers can meet the challenges from complex workloads using a single stack. MariaDB Enterprise Server includes pluggable smart storage engines to meet specific workload needs and connectors for high-performance data access by applications.

MariaDB Enterprise ColumnStore is a columnar storage engine designed to handle the extremely large data sets and ad hoc queries of analytical workloads. Data is written to disk by column rather than row and is automatically partitioned. Columnar data storage is designed to deliver real time analysis on billions of rows. MariaDB Enterprise ColumnStore is a plugin storage engine and is included with MariaDB Enterprise Server.

MariaDB Direct Query Adapter enables Power BI users to work with remote data without the need to download it onto the local machine. Downloading analytical data sets can present challenges such as download speed and inadequate memory on a local machine, and even a powerful laptop or desktop is outperformed by the processing power of a high end server or MPP system. MariaDB's Direct Query Adapter enables users to avoid these limitations and provides robust querying and data visualization from any location.

Requirements

MariaDB Direct Query Adapter for Microsoft Power BI requires:

- Microsoft Power BI Desktop
- MariaDB ODBC Connector v3.1.10 or later.

Download and Install

To use MariaDB Direct Query Adapter with Microsoft Power BI Desktop:

1. Check the system requirements for Microsoft Power BI Desktop.
2. Download Microsoft Power BI Desktop using the Microsoft instructions.
3. Download MariaDB ODBC Connector.
4. Select MariaDB ODBC Connector v3.1.10 or later for Windows.
5. Click on the download or choose "Open" to start the MariaDB ODBC Connector Setup Wizard.
6. Click "Next".
7. Read and accept the terms and agreement.
8. Click "Next".
9. Choose "Typical" for installation type and click "Install".
10. When asked if you want to allow this app to makes changes to your device, click "Yes".
11. If you have older versions of MariaDB ODBC Connector 64-bit, select "Make User DSN's for older Connector version to use this version" and click "Finish". Otherwise, just click "Finish".

Connect

Connect to your remote MariaDB database from Power BI Desktop using the MariaDB Direct Query Adapter.

1. Open Microsoft Power BI Desktop.
2. From the Power BI home screen, choose Get Data->More. Enter "MariaDB". Select MariaDB from the menu and click "Connect".
3. Enter the data source. This is an IP address and port number, or in the case of MariaDB Cloud, it is the qualified domain name and port number.
4. Select "DirectQuery" and click "OK".
5. Enter your user name and password and click "Connect".

You are now connected to your remote MariaDB database and can use Microsoft Power BI to run queries without the need to download the data locally.

Queries

The MariaDB Direct Query Adapter for Power BI interacts with the SQL layer. It is upstream of the storage engine, so queries can be done regardless of the underlying storage engine.

For example, MariaDB Direct Query Adapter for Microsoft Power BI can be used to query data on a row-based transactional database using the InnoDB storage engines or a column-based data warehouse using the MariaDB Enterprise ColumnStore storage engine to deliver real time analysis of billions of rows of data.

Relationships

Power BI depends on relationships for data analysis. These relationships are automatically established for row-based databases, for example those using the InnoDB storage engine.

Because column-based storage engines such as MariaDB Enterprise ColumnStore do not use indexes, relationships must be set up manually. For more about creating relationships in Power BI see Create and Manage Relationships in Power BI.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Logging Tools

See mariadb-binlog.

Use mariadb-binlog to process binary log files. This utility is essential for examining replication events, recovering from data loss, and auditing changes in your MariaDB Server.

See mariadb-dumpslow.

Summarize and analyze the MariaDB slow query log with mariadb-dumpslow (formerly mysqldumpslow), grouping similar queries to surface the slowest statements.

Using mariadb-binlog

> **Note:**
>
> Previously, the client was called `mysqlbinlog`. It can still be accessed under this name, via a symlink in Linux, or an alternate binary in Windows.

Overview

The MariaDB server's binary log is a set of files containing "events" which represent modifications to the contents of a MariaDB database.

Events are written in a binary (that is, non-human-readable) format. The `mariadb-binlog` utility is used to view these events in plain text.

Run mariadb-binlog from a command line:

```
mariadb-binlog [options] binlog-filename [binlog-filename ...]
```

See mariadb-binlog Options for details on the available options.

Usage

Display the contents of a binary log file named `mariadb-bin.000152` like this:

```
mariadb-binlog mariadb-bin.000152
```

Processing a Single Log File

The logging format is determined by the value of the binlog_format system variable. If you are using statement-based logging, the output includes the SQL statement, the ID of the server the statement was executed on, a timestamp, and how much time the statement took to execute. If you are using row-based logging, the output of an event will not include an SQL statement, but will instead output how individual rows were changed.

The output from `mariadb-binlog` can be used as input to the `mariadb` client to redo the statements contained in a binary log. This is useful for recovering after a server crash (replace *binlog-filename* with the name of a binary log file):

```
mariadb-binlog binlog-filename | mysql -u root -p
```

If you would like to view and possibly edit the file before applying it to your database, use the `-r` flag to redirect the output to a file (replace *outputfile* with the name of a file to store the output, and *binlog-filename* with the name of a binary log file):

```
mariadb-binlog -r outputfile binlog-filename
```

In the output file, delete any statements you don't want executed (such as an accidental `DROP DATABASE`). Once you are satisfied with the contents, you can execute it:

```
mariadb -u root -p --binary-mode < outputfilename
```

Be careful to process multiple log files in a single connection, especially if one or more of them have any `CREATE TEMPORARY TABLE ...` statements. Temporary tables are dropped when the mariadb client terminates, so if you are processing multiple log files one at a time (i.e. multiple connections), and one log file creates a temporary table and then a subsequent log file refers to the table, you get an 'unknown table' error.

Processing Multiple Log Files

To execute multiple log files using a single connection, list them all on the `mariadb-binlog` command line:

```
mariadb-binlog mariadb-bin.000001 mariadb-bin.000002 | mariadb -u root -p --binary-mode
```

If you need to manually edit the binlogs before executing them, combine them all into a single file before processing:

```
mariadb-binlog mariadb-bin.000001 > /tmp/mariadb-bin.sql
mariadb-binlog mariadb-bin.000002 >> /tmp/mariadb-bin.sql
# make any edits
mariadb -u root -p -e "source /tmp/mariadb-bin.sql"
```

mariadb-binlog Options

> **Note:**
>
> Previously, the client was called `mysqlbinlog`. It can still be accessed under this name, via a symlink in Linux, or an alternate binary in Windows.

Options

mariadb-binlog is a utility included with MariaDB for processing binary log and relay log files.

The following options are supported by mariadb-binlog. They can be specified on the command line or in option files.

-?, –help

Display a help statement.

> **CURRENT**
>
> **–base64-output=_name_**
>
> Determine when the output statements should be base64-encoded `BINLOG` statements. Options (case-insensitive) include `auto`, `unspec`, `never` ,and `decode-rows`. `never` neither prints base64 encodings nor verbose event data, and exits on error if a row-based event is found. This option is useful for binlogs that are entirely statement-based. `decode-rows` decodes row events into commented SQL statements if the `--verbose` option is also given. It can enhance the debugging experience with large binary log files, as the raw data is omitted. Unlike `never`, mariadb-binlog does not exit with an error if a row event is found. `auto` (synonymous with `unspec`) outputs base64 encoded entries for row-based and format description events; it should be used when `ROW`-format events are processed for re-executing on the MariaDB server. This behavior is presumed, such that `auto` is the default value when no option specification is provided. The other option values are intended only for debugging or testing purposes because they may produce output that does not include all events in executable form.
>
> **< 10.6 / 10.5.10**
>
> **–base64-output[=_name_]**
>
> Determine when the output statements should be base64-encoded BINLOG statements. Options (case-insensitive) include `auto`, `unspec`, `always` (deprecated), `never` , and `decode-rows`. `never` disables it and works only for binlogs without row-based events; `decode-rows` decodes row events into commented SQL statements if the `--verbose` option is also given. Unlike `never`, `mariadb-binlog` does not exit with an error if a row event is found `auto` or `unspec`, the default, prints base64 only when necessary (for instance, for row-based events and format description events), and is the only safe behavior if you intend to use the output of `mariadb-binlog` to re-execute binary log file contents. The other option values are intended only for debugging or testing purposes, because they may produce output that does not include all events in executable form. `always` prints base64 whenever possible, and is for debugging only and should not be used in a production system. If this option is not given, the default is `auto`; if it is given with no argument, `always` is used.

Default value: `auto`.

–binlog-row-event-max-size=*val*

The maximum size in bytes of a row-based binary log event. Should be a multiple of 256. Minimum 256, maximum `18446744073709547520`. Default value: `4294967040` (4GB)

–character-sets-dir=*name*

Directory where the character sets are.

-d, –database=*name*

Output entries from the binary log (local log only) that occur while the name has been selected as the default database by USE. Only one database can be specified. The effects depend on whether the statement-based or row-based logging format is in use. For statement-based logging, the server only logs statements where the default database is *name*. The default database is set with the USE statement. For row-based logging, the server logs any updates to any tables in the named database, irrespective of the current database. Ignored in `--raw` mode.

[options], –debug[=options]

In a debug build, write a debugging log. A typical debug options string is `d:t:o,file\_name`. Default value: `d:t:o,/tmp/mariadb-binlog.trace`

–debug-check

Print some debug info at exit. Default value: `FALSE`

–debug-info

Print some debug info and memory and CPU info at exit. Default value: `FALSE`

–default-auth=*name*

Default authentication client-side plugin to use.

–defaults-extra-file=*name*

Read the file name, which can be the full path or the path relative to the current directory, after the global files are read.

–defaults-file=*name*

Only read default options from the given file name, which can be the full path or the path relative to the current directory.

–defaults-group-suffix=*str*

Also read groups with a suffix of *str*. For example, since `mariadb-binlog` normally reads the `[client]` and `[mysqlbinlog]` groups, `--defaults-group-suffix=x` would cause it to also read the groups `\[mysqlbinlog\_x]` and `\[client\_x]`.

-D, –disable-log-bin

Disable binary log. This is useful if you enabled `--to-last-log` and are sending the output to the same MariaDB server. This way, you could avoid an endless loop. You would also like to use it when restoring after a crash to avoid duplication of the statements you already have. The `SUPER` privilege is needed to use this option. Default value: `FALSE`

–do-domain-ids=*name*

A list of positive integers, separated by commas, that form a whitelist of domain ids. Any log event with a GTID that originates from a domain id specified in this list is displayed. Cannot be used with `--ignore-domain-ids`. When used with `--ignore-server-ids` or `--do-server-ids`, the result is the intersection between the two datasets. Available from MariaDB 10.9.

–do-server-ids=*name*

A list of positive integers, separated by commas, that form a whitelist of server ids. Any log event originating from a server id specified in this list is displayed. Cannot be used with `--ignore-server-ids`. When used with `--ignore-domain-ids` or `do-domain-ids`, the result is the intersection between the two datasets. Alias for `--server-id`. Available from MariaDB 10.9.

-B, –flashback

Support flashback mode. Default value: `FALSE`

-F, –force-if-open

Force if binlog was not closed properly. Defaults to `ON`; use `--skip-force-if-open` to disable. Default value: `TRUE`

-f, –force-read

If `mariadb-binlog` reads a binary log event that it does not recognize, it prints a warning, ignores the event, and continues. Without this option, `mariadb-binlog` stops if it reads such an event. Default value: `FALSE`

–gtid-strict-mode

Process binlog according to `gtid-strict-mode` specification. The start, stop positions are verified to satisfy the start < stop comparison condition. Sequence numbers of any GTID domain must comprise a monotonically growing sequence. Defaults to `ON`; use `--skip-gtid-strict-mode` to disable. Available from MariaDB 10.8. Default value: `TRUE`

-H, –hexdump

Augment output with hexadecimal and ASCII event dump. Default value: `FALSE`

-h, –host=*name*

Get the binlog from the MariaDB server on the given host.

–ignore-domain-ids=*name*

A list of positive integers, separated by commas, that form a blacklist of domain ids. Any log event with a GTID that originates from a domain id specified in this list is hidden. Cannot be used with `--do-domain-ids`. When used with `--ignore-server-ids` or `--do-server-ids`, the result is the intersection between the two datasets. Available from MariaDB 10.9.

–ignore-server-ids=*name*

A list of positive integers, separated by commas, that form a blacklist of server ids. Any log event originating from a server id specified in this list is hidden. Cannot be used with `--do-server-ids`. When used with `--ignore-domain-ids` or `--do-domain-ids`, the result is the intersection between the two datasets. Available from MariaDB 10.9.

-l path, –local-load=*path*

Prepare local temporary files for LOAD DATA INFILE in the specified directory. The temporary files are not automatically removed.

–no-defaults

Don't read default options from any option file.

-o value, –offset=*value*

Skip the first value entries in the log. Default value: `0`

–open_files_limit=#

Reserve file descriptors for usage by mariadb-binlog. Default value: `64`

-p[*passwd*], –password[=*passwd*]

Password to connect to the remote server. The password can be omitted, allow it to be entered from the prompt, or an option file can be used to avoid the security risk of passing a password on the command line.

–plugin-dir=*dir_name*

Directory for client-side plugins.

-P *num*, –port=*num*

Port number to use for connection or `0` for default to, in order of preference, `my.cnf`, `$MYSQL_TCP_PORT`, `/etc/services`, built-in default (`3306`). Default value: `0`

–position=#

Removed. Use `--start-position` instead.

–print-defaults

Print the program argument list from all option files and exit.

–print-row-count

Print row counts for each row of events. (Defaults to `ON`; use `--skip-print-row-count` to disable.) Default value: `TRUE`

–print-row-event-positions

Print row event positions. Defaults to on; use `--skip-print-row-event-positions` to disable.) Default value: `TRUE`

print-table-metadata

Print metadata stored in `Table_map_log_event`.

–protocol=*name*

The protocol of the connection (`tcp`, `socket`, `pipe`, `memory`).

–raw

Requires `-R`. Output raw binlog data instead of SQL statements. Output files are named after server logs.

-R, –read-from-remote-server

Read binary logs from a remote MariaDB server rather than reading a local log file. Any connection parameter options are ignored unless this option is given as well. These options are `--host`, `--password`, `--port`, `--protocol`, `--socket`, and `--user`. This option requires that the remote server be running. It works only for binary log files on the remote server, not relay log files. Default value: `FALSE`

-r name, –result-file=*name*

Direct output to a given file. With `--raw`, this is a prefix for the file names.

–rewrite-db=*name*

Updates to a database with a different name than the original. Example: `rewrite-db='from->to'`. For events that are logged as statements, rewriting the database constitutes changing a statement's default database from `db1` to `db2`. There is no statement analysis or rewrite of any kind; that is, if you specify `db1.tbl` in the statement explicitly, that occurrence won't be changed to `db2.tbl`. Row-based events are rewritten correctly to use the new database name. Filtering (for instance, with `--database=name`) happens before the database rewrites have been performed. If you use this option on the command line and `>` has a special meaning to your command interpreter, quote the value (for instance, `--rewrite-db="oldname->newname"`).

–server-id=*idnum*

Extract only binlog entries created by the server having the given id. From MariaDB 10.9, an alias for `--do-server-ids`. Default value: `0`

–set-charset=*character_set*

Add `SET NAMES character_set` to the output to specify the character set to be used for processing log files.

–shared-memory-base-name=*name*

Shared-memory *name* to use for Windows connections using shared memory to a local server (started with the `--shared-memory` option). Case-sensitive. Default value: `MYSQL`

-s, –short-form

Just show regular queries: no extra info and no row-based events. This is for testing only, and should not be used in production systems. If you want to suppress base64-output, consider using `--base64-output=never` instead. Default value: `FALSE`

–skip-annotate-row-events

Skip all Annotate_rows events in the mariadb-binlog output (by default, `mariadb-binlog` prints `Annotate_rows` events if the binary log contains them).

-S, –socket=*name*

For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

–ssl

Enables TLS. TLS is also enabled even without setting this option when certain other TLS options are set. The `--ssl` option does not enable verifying the server certificate by default. In order to verify the server certificate, you must specify the `--ssl-verify-server-cert` option. Default value: `FALSE`

–ssl-ca=*name*

Defines a path to a PEM file that should contain one or more X509 certificates for trusted Certificate Authorities (CAs) to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option implies the `--ssl` option.

–ssl-capath=*name*

Defines a path to a directory that contains one or more PEM files that should each contain one X509 certificate for a trusted Certificate Authority (CA) to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the openssl rehash command. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option is only supported if the client was built with OpenSSL or yaSSL. If the client was built with GnuTLS or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms. This option implies the `--ssl` option.

–ssl-cert=*name*

Defines a path to the X509 certificate file to use for TLS. This option requires that you use the absolute path, not a relative path. This option implies the `--ssl` option.

–ssl-cipher=*name*

List of permitted ciphers or cipher suites to use for TLS. This option implies the `--ssl` option.

–ssl-crl=*name*

Defines a path to a PEM file that should contain one or more revoked X509 certificates to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL or Schannel. If the client was built with yaSSL or GnuTLS, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.

–ssl-crlpath=*name*

Defines a path to a directory that contains one or more PEM files that should each contain one revoked X509 certificate to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the openssl rehash command. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL. If the client was built with yaSSL, GnuTLS, or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.

–ssl-key=*name*

Defines a path to a private key file to use for TLS. This option requires that you use the absolute path, not a relative path. This option implies the `--ssl` option.

–ssl-verify-server-cert

Enables server certificate verification. This option is disabled by default. Default value: `FALSE`

–start-datetime=*datetime*

If specified, start reading the binlog at the first event having a datetime equal to or later than the argument; the argument must be a date and time in the local time zone, in any format accepted by the MariaDB server for DATETIME and TIMESTAMP types, for example: `2014-12-25 11:25:56` (you should probably use quotes for your shell to set it properly). This option is useful for point-in-time recovery.

-j pos, –start-position=*pos*

Start reading the binlog at this position. Type can either be a positive integer or, from MariaDB 10.8, a GTID list. When using a positive integer, the value only applies to the first binlog passed on the command line. In GTID mode, multiple GTIDs can be passed as a comma-separated list, where each must have a unique domain id. The list represents the GTID binlog state that the client (another "replica" server) is aware of. Therefore, each GTID is exclusive; only events after a given sequence number are printed to allow users to receive events after their current state. Default value: `4`

> **Warning:**
>
> Options `--start-position` and `--stop-position` currently compare Sequence Numbers only per Domain ID and ignore Server IDs. This is incorrect, as it is different from the Replication design for GTIDs, which compares per Domain–Server ID pair. MDEV-37231 tracks this bug.

–stop-datetime=*name*

If specified, stop reading the binlog at the first event having a datetime equal to or posterior to the argument; the argument must be a date and time in the local time zone, in any format accepted by the MariaDB server for `DATETIME` and `TIMESTAMP` types, for example: `2014-12-25 11:25:56` (you should probably use quotes for your shell to set it properly). Ignored in `--raw` mode.

> **≥ 10.11.14**
>
> Emit a warning if the specified time is not found within the specified binlogs.

–stop-never

Wait for more data from the server (and thus requires `-R` or `--read-from-remote-server`) instead of stopping at the end of the last log. Implies `--to-last-log`.

–stop-never-slave-server-id

The replica server_id used for `--read-from-remote-server` `--stop-never`.

–stop-position=*position*

If specified, stop reading the binlog at this *position*. Type can either be a positive integer or, from MariaDB 10.8, a GTID list. When using a positive integer, the value only applies to the last binlog passed on the command line. In GTID mode, multiple GTIDs can be passed as a comma-separated list, where each must have a unique domain id. Each GTID is inclusive; only events up to the given sequence numbers are printed. Ignored in `--raw` mode.

> **≥ 10.11.14**
>
> Emit a warning if the specified position or GTID is not within the specified binlogs.
>
> **≥ 10.5.27**
>
> Emit a warning if the specified position is beyond the end of the last binlog.

> **Warning:**
>
> Options `--start-position` and `--stop-position` currently compare Sequence Numbers only per Domain ID and ignore Server IDs. This is incorrect, as it is different from the Replication design for GTIDs, which compares per Domain–Server ID pair. MDEV-37231 tracks this bug.

-T, –table

List entries for just this table (affects only row events).

–tls-version=*name*

This option accepts a comma-separated list of TLS protocol versions. A TLS protocol version will only be enabled if it is present in this list. All other TLS protocol versions will not be permitted. See Secure Connections Overview: TLS Protocol Versions for more information. Default value: `TLSv1.1,TLSv1.2,TLSv1.3`

-t, –to-last-log

Requires `-R` or `--read-from-remote-server`. Does not stop at the end of the requested binlog but rather continues printing until the end of the last binlog of the MariaDB server. If you send the output to the same MariaDB server, that may lead to an endless loop. Default value: `FALSE`

-u, –user=*username*

Connect to the remote server as *username*.

-v, –verbose

Reconstruct SQL statements out of row events. `-v -v` adds comments on column data types.

-V, –version

Print version and exit.

–verify-binlog-checksum

Verify binlog event checksums when reading a binlog file.

Option Files

In addition to reading options from the command line, `mariadb-binlog` can also read options from option files. If an unknown option is provided to `mariadb-binlog` in an option file, it is ignored.

The following options relate to how MariaDB command line tools handle option files. They must be given as the first argument on the command line:

Option	Description
–print-defaults	Print the program argument list and exit.
–no-defaults	Don't read default options from any option file.
–defaults-file=#	Only read default options from the given file #.
–defaults-extra-file=#	Read this file after the global files are read.
–defaults-group-suffix=#	In addition to the default option groups, also read option groups with this suffix.

`mariadb-binlog` is linked with MariaDB Connector/C. However, MariaDB Connector/C does not handle the parsing of option files for this client. That is performed by the server's option file parsing code. See MDEV-19035 for more information.

Option Groups

`mariadb-binlog` reads options from the following option groups from the option files:

Group	Description
[mysqlbinlog]	Options read by mariadb-binlog, which includes both MariaDB Server and MySQL Server.
[mariadb-binlog]	Options read by mariadb-binlog.
[client]	Options read by all MariaDB and MySQL client programs, which include both MariaDB and MySQL clients. For example, mysqldump.
[client-server]	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which are common between the server and the clients.
[client-mariadb]	Options read by all MariaDB client programs.

This page is licensed: CC BY-SA / Gnu FDL

Annotate_rows_log_event

> **Note:**
>
> The terms *master* and *slave* have historically been used in replication, and MariaDB has begun the process of adding *primary* and *replica* synonyms. The old terms will continue to be used to maintain backward compatibility - see MDEV-18777 to follow progress on this effort.

Overview

`Annotate_rows` events accompany `row` events and describe the query which caused the row event.

In the binary log, each `Annotate_rows` event precedes the corresponding Table map event or the first of the Table map events, if there are more than one (for instance, in a case of multi-delete or insert delayed).

Example

```
master> DROP DATABASE IF EXISTS test;
master> CREATE DATABASE test;
master> USE test;
master> CREATE TABLE t1(a int);
master> INSERT INTO t1 VALUES (1), (2), (3);
master> CREATE TABLE t2(a int);
master> INSERT INTO t2 VALUES (1), (2), (3);
master> CREATE TABLE t3(a int);
master> INSERT DELAYED INTO t3 VALUES (1), (2), (3);
master> DELETE t1, t2 FROM t1 INNER JOIN t2 INNER JOIN t3
    ->        WHERE t1.a=t2.a AND t2.a=t3.a;

master> SHOW BINLOG EVENTS IN 'master-bin.000001';

Options

The following options control the behavior of `Annotate_rows_log_event`.

Master Option: `--binlog-annotate-row-events`

This option tells the master to write `Annotate_rows` events to the binary log. See binlog_annotate_row_events for a detailed description of the variable.

Session values allow to annotate only some selected statements:

```
...
SET SESSION binlog_annotate_row_events=ON;
... statements to be annotated ...
SET SESSION binlog_annotate_row_events=OFF;
... statements not to be annotated ...
```

Replica Option: `--replicate-annotate-row-events`

This option tells the replica to reproduce `Annotate_row` events received from the master in its own binary log (sensible only when used in tandem with the `log-slave-updates` option).

See replicate_annotate_row_events for a detailed description of the variable.

mariadb-binlog Option: `--skip-annotate-row-events`

This option tells mariadb-binlog to skip all `Annotate_row` events in its output (by default, mariadb-binlog prints `Annotate_row` events, if the binary log contains them).

Example of mariadb-binlog Output

```
...> mariadb-binlog.exe -vv -R --user=root --port=3306 --host=localhost master-bin.000001

mysqlbinlog

`mysqlbinlog` is a client tool which is called `mariadb-binlog` now. It can still be accessed under its original name via a symlink in Linux, or an alternate binary in Windows.

This page is licensed: CC BY-SA / Gnu FDL

mariadb-dumpslow

> **Note:**
>
> Previously, the client was called `mysqldumpslow`. It can still be accessed under this name, via a symlink in Linux, or an alternate binary in Windows.

`mariadb-dumpslow` is a tool to examine the slow query log.

It parses the slow query log files, printing a summary result. Normally, `mariadb-dumpslow` groups queries that are similar, except for the particular values of number and string data values. It “abstracts” these values to N and ´S´ when displaying summary output. The `-a` and `-n` options can be used to modify value abstracting behavior.

Usage

```
mariadb-dumpslow [ options... ] [ logs... ]
```

Options

`-a`

Don’t abstract all numbers to N and strings to ‘S’.

`-d`, **`--debug`**

Debug mode.

`-g`` *pattern*

Grep: only consider statements that include this string *pattern*.

`--help`

Display help.

`-h`` *hostname*

Hostname of db server for -slow.log filename (can be a wildcard). The Default is `''`, that is, match all hosts.

`-i`` *name*

Name of server instance (if using mysql.server startup script).

`-l`

Don't subtract lock time from total time.

`-j`, **`--json`**

Stores the dumped data in JSON format. Available from MariaDB 12.1.

`-n`` *number*

Abstract numbers with at least this *number* of digits within names.

`-r`

Reverse the sort order (largest last instead of first).

`-s`` *order*

What to sort by (`aa`, `ae`, `al`, `ar`, `at`, `a`, `c`, `e`, `l`, `r`, `t`). The default is `at`. The meaning of the abbreviations is:

- `aa` – average rows affected
- `ae` – aggregated number of rows examined
- `al` – average lock time
- `ar` – average rows sent
- `at` – average query time
- `a` – rows affected
- `c` – count
- `e` – rows examined
- `l` – lock time
- `r` – rows sent
- `t` – query time:

`-t`` *number*

Just show the top *number of queries*.

`-v`, **`--verbose`**

Verbose mode.

mariadb Client

See mariadb Command-Line Client.

Complete MariaDB command-line client guide. Complete reference for server connections, query execution, data import, and batch processing for production use.

See mysql Command-Line Client.

The mysql command-line client is the former name of the mariadb SQL shell, still available as a symlink or alternate binary for compatibility.

This page is licensed: CC BY-SA / Gnu FDL

mariadb Command-Line Client

`mariadb` is a simple SQL shell with GNU readline capabilities.

> **CURRENT**
>
> The command-line client is called `mariadb`. On Unix system, a symlink named `mysql` is available. On Windows, an alternative binary named `mysql.exe` is available.
>
> **< 10.5**
>
> The command-line client is called `mysql`.

Overview

`mariadb` supports interactive and non-interactive use. When used interactively, query results are presented in an ASCII-table format. When used non-interactively (for example, as a filter), the result is presented in tab-separated format. The output format can be changed using command options.

If you have problems due to insufficient memory for large result sets, use the `--quick` option. This forces mariadb to retrieve results from the server a row at a time rather than retrieving the entire result set and buffering it in memory before displaying it. This is done by returning the result set using the `mysql_use_result()` C API function in the client/server library rather than `mysql_store_result()`.

Invoke the client from the prompt of your command interpreter (for instance, `cmd` on Windows, `Terminal` on macOS) as follows:

```
mariadb db_name
```

Alternatively, start the client and log on to MariaDB server:

```
mariadb --user=user_name --password=your_password db_name
```

Type an SQL statement, end it with a semicolon (`;`), `\g`, or `\G` , and press `Enter`.

Typing `Control-C` causes `mariadb` to attempt to kill the current statement. If this cannot be done, or `Control-C` is typed again before the statement is killed, `mariadb` exits.

You can execute SQL statements in a script file (batch file) like this:

```
mariadb db_name < script.sql > output.tab
```

Usage

The client's general syntax is:

```
mariadb <options>
```

Options

`mariadb` supports the following options:

`-?, --help`

Display help and exit.

`-I, --help`

Synonym for `-?`

`--abort-source-on-error`

Abort ‘source filename’ operations in case of errors.

`--auto-rehash`

Enable automatic rehashing. This option is on by default, which enables database, table, and column name completion. Use `--disable-auto-rehash`, `--no-auto-rehash` or `skip-auto-rehash` to disable rehashing. That causes mariadb to start faster, but you must issue the rehash command if you want to use name completion. To complete a name, enter the first part and press Tab. If the name is unambiguous, mariadb completes it. Otherwise, you can press Tab again to see the possible names that begin with what you have typed so far. Completion does not occur if there is no default database.

`-A, --no-auto-rehash`

No automatic rehashing. One has to use ‘rehash’ to get table and field completion. This gives a quicker start of mariadb and disables rehashing on reconnect.

`--auto-vertical-output`

Automatically switch to vertical output mode if the result is wider than the terminal width.

`-B, --batch`

Print results using tab as the column separator, with each row on a new line. With this option, mariadb does not use the history file. Batch mode results in nontabular output format and escaping of special characters. Escaping may be disabled by using raw mode; see the description for the `--raw` option. (Enables `--silent`.)

`--binary-mode`

By default, `ASCII '\0'` is disallowed and `\r\n` is translated to `\n`. This switch turns off both features, and also turns off parsing of all client commands except `\C` and `DELIMITER`, in non-interactive mode (for input piped to mariadb or loaded using the `source` command). This is necessary when processing output from mariadb-binlog that may contain blobs.

`--character-sets-dir=name`

Directory for character set files.

`--column-names`

Write column names in results. (Defaults to `ON`; use `--skip-column-names` to disable.)

`--column-type-info`

Display column type information.

`-c, --comments`

Preserve comments. Send comments to the server. The default is `--skip-comments` (discard comments), enable with `--comments`.

`-C, --compress`

Compress all information sent between the client and the server if both support compression.

`--connect-expired-password`

Notify the server that this client is prepared to handle expired password sandbox mode even if `--batch` was specified.

`--connect-timeout=`*`num`*

Number of seconds before connection timeout. Defaults to `0`.

`-D, --database=`*`name`*

Database to use.

`-#[`*`options`*`], --debug[=`*`options`*`]`

On debugging builds, write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o,/tmp/mysql.trace`.

`--debug-check`

Check memory and open file usage at exit.

`-T, --debug-info`

Print some debug info at exit.

`--default-auth=`*`plugin`*

Default authentication client-side plugin to use.

`--default-character-set=`*`name`*

Set the default character set. A common issue that can occur when the operating system uses utf8 or another multibyte character set is that output from the mariadb client is formatted incorrectly, due to the fact that the MariaDB client uses the latin1 character set by default. You can usually fix such issues by using this option to force the client to use the system character set instead. If set to `auto` the character set is taken from the client environment (`LC_CTYPE` on Unix).

`--defaults-extra-file=`*`file`*

Read this *file* after the global files are read. Must be given as the first option.

`--defaults-file=`*`file`*

Only read default options from the given *file*. Must be given as the first option.

`--defaults-group-suffix=`*`suffix`*

In addition to the given groups, also read groups with this *suffix*.

`--delimiter=`*`name`*

Delimiter to be used. The default is the semicolon (`;`).

`--enable-cleartext-plugin`

Obsolete option. Exists only for MySQL compatibility.

`-e, --execute=`*`name`*

Execute statement and quit. Disables `--force` and history file. The default output format is like that produced with `--batch`.

`-f, --force`

Continue even if we get an SQL error. Sets `--abort-source-on-error` to `0`.

`-h, --host=`*`host`*

Connect to *host*.

`-H, --html`

Produce HTML output.

`-U, --i-am-a-dummy`

Synonym for option `--safe-updates`, `-U`.

`-i, --ignore-spaces`

Ignore space after function names. Allows one to have spaces (including tab characters and new line characters) between function name and '('. The drawback is that this causes built in functions to become reserved words.

`--init-command=str`

SQL Command to execute when connecting to the MariaDB server. Will automatically be re-executed when reconnecting.

`--line-numbers`

Write line numbers for errors. (Defaults to `ON`; use `--skip-line-numbers` to disable.)

`--local-infile`

Enable or disable LOCAL capability for LOAD DATA INFILE. With no value, the option enables `LOCAL`. The option may be given as `--local-infile=0` or `--local-infile=1` to explicitly disable or enable `LOCAL`. Enabling `LOCAL` has no effect if the server does not also support it.

`--max-allowed-packet=`*`num`*

The maximum packet length to send to or receive from server. The default is 16MB, the maximum 1GB.

`--max-join-size=`*`num`*

Automatic limit for rows in a join when using `--safe-updates`. Default is `1000000`.

`-G, --named-commands`

Enable named commands. Named commands mean mariadb's internal commands (see below) . When enabled, the named commands can be used from any line of the query, otherwise only from the first line, before an enter. Long-format commands are allowed, not just short-format commands. For example, `quit` and `\q` are both recognized. Disable with `--disable-named-commands`. This option is disabled by default.

`--net-buffer-length=`*`num`*

The buffer size for TCP/IP and socket communication. Default is 16KB.

`-b, --no-beep`

Turn off beep on error.

`--no-defaults`

Don't read default options from any option file. Must be given as the first option.

`-o, --one-database`

Ignore statements except those that occur while the default database is the one named on the command line. This filtering is limited, and based only on USE statements. This is useful for skipping updates to other databases in the binary log.

`--pager[=name]`

Pager to use to display results (Unix only). If you don't supply an option, the default pager is taken from your ENV variable PAGER. Valid pagers are *less*, *more*, *cat [> filename]*, etc. See interactive help (\h) also. This option does not work in batch mode. Disable with `--disable-pager`. This option is disabled by default.

`-p, --password[=`*`password`*`]`

Password to use when connecting to server. If you use the short option form (`-p`), you cannot have a space between the option and the password. If you omit the password value following the `--password` or `-p` option on the command line, mariadb prompts for one. Specifying a password on the command line should be considered insecure. You can use an option file to avoid giving the password on the command line.

`--plugin-dir=`*`name`*

Directory for client-side plugins.

`-P, --port=`*`num`*

Port number to use for connection or `0` for default to, in order of preference, `my.cnf`, `$MYSQL_TCP_PORT`, `/etc/services`, built-in default (`3306`).

`--print-defaults`

Print the program argument list and exit. Must be given as the first option.

`--progress-reports`

Get progress reports for long running commands (such as ALTER TABLE). (Defaults to `ON`; use `--skip-progress-reports` to disable.)

`--prompt=`*`name`*

Set the mariadb prompt to this value. See prompt command for options.

`--protocol=`*`name`*

The protocol to use for connection (`tcp`, `socket`, `pipe`, `memory`).

`-q, --quick`

Don't cache result, print it row by row. This may slow down the server if the output is suspended. Doesn't use history file.

`--quick-max-column-width=N`

> **CURRENT**
>
> Maximal field length limit in case of `--quick`.
>
> **< 11.7.1 / 11.6.2 / 11.4.4 / 10.11.10 / 10.6.20 / 10.5.27**
>
> This option is not available.

`-r, --raw`

For tabular output, the "boxing" around columns enables one column value to be distinguished from another. For nontabular output (such as is produced in batch mode or when the `--batch` or `--silent` option is given), special characters are escaped in the output so they can be identified easily. Newline, tab, NUL, and backslash are written as `\n`, `\t`, `\0`, and `\\`. The `--raw` option disables this character escaping.

`--reconnect`

Reconnect if the connection is lost. This option is enabled by default. Disable with `--disable-reconnect` or `skip-reconnect`.

`-U, --safe-updates`

Allow only those UPDATE and DELETE statements that specify which rows to modify by using key values. If you have set this option in an option file, you can override it by using `--safe-updates` on the command line. See using the –safe-updates option for more.

`--sandbox`

> **CURRENT**
>
> Disallow commands that access the file system (except `\P` without an argument and `\e`). Disabled commands include system (`\!`), tee (`\T`), pager with an argument(`\P`` ``` *foo*), source (`\.`). Using a disabled command is an error, which can be ignored with `--force`. A sandbox command (`\-`) enables the sandbox mode until EOF (current file or the session, if interactive).
>
> **< 11.4.2 / 11.2.4 / 11.1.5 / 11.0.6 / 10.11.8 / 10.6.18 / 10.5.25**
>
> This option is not available.

`--script-dir=`*`name`*

> **CURRENT**
>
> Sets an alternative directory path for searching scripts invoked via the source command.
>
> **< 12.0**

> This option is not available.

`--secure-auth`

Refuse client connecting to server if it uses old (pre-MySQL4.1.1) protocol. Defaults to `FALSE`.

`--select-limit=`*`num`*

Automatic limit for `SELECT` when using `--safe-updates`. Default `1000`.

`--server-arg=`*`name`*

Send embedded server this as a parameter.

`--shared-memory-base-name=`*`name`*

Shared-memory name to use for Windows connections using shared memory to a local server (started with the `--shared-memory` option). Case-sensitive.

`--show-serveroutput`

Enables displaying of `DBMS_OUTPUT` messages. See this page for details.

`--show-warnings`

Show warnings after every statement. Applies to interactive and batch mode.

`--sigint-ignore`

Ignore `SIGINT` signals (usually `CTRL-C`).

`-s, --silent`

Be more silent. This option can be given multiple times to produce less and less output. This option results in nontabular output format and escaping of special characters. Escaping may be disabled by using raw mode; see the description for the `--raw` option.

`--skip-auto-rehash`

Disable automatic rehashing. See `--auto-rehash`.

`-N, --skip-column-names`

Don't write column names in results. See `--column-names`.

`--skip-comments`

Discard comments. Set by default, see `--comments` to enable.

`-L`, `--skip-line-numbers`

Don't write line number for errors. See `--line-numbers`.

`--skip-progress-reports`

Disables getting progress reports for long running commands. See `--progress-reports`.

`--skip-reconnect`

Don't reconnect if the connection is lost. See `--reconnect`.

`-S, --socket=name`

For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use. The socket file can exist in different locations depending on setup. Common locations include:

- Debian-based, Ubuntu: `/var/run/mysqld/mysqld.sock`
- SUSE: `/var/run/mysql/mysql.sock`
- Red Hat: `/var/lib/mysql/mysql.sock`
- Other: `/tmp/mysql.sock`

`--ssl`

> **CURRENT**
>
> Enables TLS. TLS is also enabled even without setting this option when certain other TLS options are set. The `--ssl` option does not enable verifying the server certificate by default. In order to verify the server certificate, the user must specify the `--ssl-verify-server-cert` option.
>
> TLS with `--ssl` is enabled by default.
>
> **< 10.10**
>
> Enables TLS. TLS is also enabled even without setting this option when certain other TLS options are set. The `--ssl` option does not enable verifying the server certificate by default. In order to verify the server certificate, the user must specify the `--ssl-verify-server-cert` option.

`--ssl-ca=name`

Defines a path to a PEM file that should contain one or more X509 certificates for trusted Certificate Authorities (CAs) to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option implies the `--ssl` option.

`--ssl-capath=name`

Defines a path to a directory that contains one or more PEM files that should each contain one X509 certificate for a trusted Certificate Authority (CA) to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the openssl rehash command. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option is only supported if the client was built with OpenSSL or yaSSL. If the client was built with GnuTLS or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms. This option implies the `--ssl` option.

`--ssl-cert=name`

Defines a path to the X509 certificate file to use for TLS. This option requires that you use the absolute path, not a relative path. This option implies the `--ssl` option.

`--ssl-cipher=name`

List of permitted ciphers or cipher suites to use for TLS. This option implies the `--ssl` option.

`--ssl-crl=name`

Defines a path to a PEM file that should contain one or more revoked X509 certificates to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL or

Schannel. If the client was built with yaSSL or GnuTLS, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.

`--ssl-crlpath=`*`name`*

Defines a path to a directory that contains one or more PEM files that should each contain one revoked X509 certificate to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the openssl rehash command. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL. If the client was built with yaSSL, GnuTLS, or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.

`--ssl-key=`*`name`*

Defines a path to a private key file to use for TLS. This option requires that you use the absolute path, not a relative path. This option implies the `--ssl` option.

`--ssl-verify-server-cert`

> **CURRENT**
>
> Enables server certificate verification. This option is enabled by default. Use `--disable-ssl` or `--disable-ssl-verify-server-cert` to revert this behavior.
>
> **< 11.4**
>
> Enables server certificate verification. This option is disabled by default.

`-t, --table`

Display output in table format. This is the default for interactive use, but can be used to produce table output in batch mode.

`--tee=`*`name`*

Append everything into outfile. See interactive help (`\h`) also. Does not work in batch mode. Disable with `--disable-tee`. This option is disabled by default.

`--tls-version=`*`name`*

This option accepts a comma-separated list of TLS protocol versions. A TLS protocol version will only be enabled if it is present in this list. All other TLS protocol versions will not be permitted. See Secure Connections Overview: TLS Protocol Versions for more information.

`--ssl-fp=`*`name`*

Server certificate fingerprint (implies `--ssl`).

`--ssl-fplist=`*`name`*

File with accepted server certificate fingerprints, one per line (implies `--ssl`).

`-n, --unbuffered`

Flush buffer after each query.

`-u`, `--user=` ***`name`***

User for login if not current user.

`-v, --verbose`

Write more. (`-v -v -v` gives the table output format).

`-V, --version`

Output version information and exit.

`-E, --vertical`

Print the output of a query (rows) vertically. Use the `\G` delimiter to apply to a particular statement if this option is not enabled.

`-w, --wait`

If the connection cannot be established, wait and retry instead of aborting.

`-X`, `--xml`

Produce XML output. See the mariadb-dump –xml option for more.

Option Files

In addition to reading options from the command line, `mariadb` can also read options from option files. If an unknown option is provided to `mariadb` in an option file, then it is ignored.

The following options relate to how MariaDB command line tools handles option files. They must be given as the first argument on the command line:

Option	Description
–print-defaults	Print the program argument list and exit.
–no-defaults	Don't read default options from any option file.
–defaults-file=#	Only read default options from the given file #.
–defaults-extra-file=#	Read this file after the global files are read.
–defaults-group-suffix=#	In addition to the default option groups, also read option groups with this suffix. If not set, MariaDB checks the $MYSQL_GROUP_SUFFIX environment variable. From MariaDB 12.0.1, MariaDB 11.8.2, MariaDB 11.4.6, MariaDB 10.11.12, `$MARIADB_GROUP_SUFFIX` is also checked, and takes precedence if both are set.

`mariadb` is linked with MariaDB Connector/C. However, MariaDB Connector/C does not handle the parsing of option files for this client. That is performed by the server option file parsing code. See MDEV-19035 for more information.

Option Groups

`mariadb` reads options from the following option groups from option files:

Group	Description
[mysql]	Options read by mysql, which includes both MariaDB Server and MySQL Server.

Group	Description
[mariadb-client]	Options read by mariadb.
[client]	Options read by all MariaDB and MySQL client programs, which includes both MariaDB and MySQL clients. For example, mysqldump.
[client-server]	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients.
[client-mariadb]	Options read by all MariaDB client programs.

Delimiters

The default delimiter in the mariadb client is the semicolon.

When creating stored programs from the command line, it is likely you will need to differentiate between the regular delimiter and a delimiter inside a BEGIN END block. Consider the following example:

```
CREATE FUNCTION FortyTwo() RETURNS TINYINT DETERMINISTIC
BEGIN
 DECLARE x TINYINT;
 SET x = 42;
 RETURN x;
END;
```

If you enter the above line by line, the mariadb client will treat the first semicolon, at the end of the `DECLARE x TINYINT` line, as the end of the statement. Since that's only a partial definition, it will throw a syntax error, as follows:

```
CREATE FUNCTION FortyTwo() RETURNS TINYINT DETERMINISTIC
BEGIN
DECLARE x TINYINT;
ERROR 1064 (42000): You have an error in your SQL syntax;
check the manual that corresponds to your MariaDB server version
 for the right syntax to use near '' at line 3
```

The solution is to specify a distinct delimiter for the duration of the process, using the `DELIMITER`. The delimiter can be any set of characters you choose, but it needs to be a distinctive set of characters that won't cause further confusion. `//` is a common choice, and used throughout the documentation.

Here's how the function can be entered, using the new delimiter:

```
DELIMITER //

CREATE FUNCTION FortyTwo() RETURNS TINYINT DETERMINISTIC
BEGIN
  DECLARE x TINYINT;
  SET x = 42;
  RETURN x;
END

//

DELIMITER ;
```

At the end, the delimiter is restored to the default semicolon. The `\g` and `\G` delimiters can always be used, even when a custom delimiter is specified.

Specify Which Protocol to Use

You can force which protocol are used to connect to the `mariadbd` server, by giving the `protocol` option one of the following values: `tcp`, `socket`, `pipe`, or `memory`.

> **CURRENT**
>
> A connection property specified via the command line (e.g. `--port=3306`) forces its type. The protocol that matches the respective connection property is used. For instance, a TCP/IP connection is created when `--port` is specified.
>
> **< 10.6.1**
>
> If `protocol` is not specified, command-line connection properties that do not force protocol are ignored.

If multiple or no connection properties are specified via the command line, the following happens on Unix and Windows systems:

Unix

- If `hostname` is not specified or `hostname` is `localhost`, Unix sockets are used.
- In other cases (`hostname` is given and it's not `localhost`) then a TCP/IP connection through the `port` option is used.

> **Warning:**
>
> `localhost` is a special value. Using `127.0.0.1` is not the same thing. The latter will connect to the `mariadbd` server through TCP/IP.

Windows

- If `shared-memory-base-name` is specified and `hostname` is not specified or `hostname` is `localhost`, then the connection will happen through shared memory.
- If `shared-memory-base-name` is not specified and `hostname` is not specified or `hostname` is `localhost`, then the connection will happen through windows named pipes.
- Named pipes will also be used if the `libmysql` / `libmariadb` client library detects that the client doesn't support TCP/IP.
- In other cases, a TCP/IP connection through the `port` option is used.

Test Which Protocol is Used

The `status` command shows you information about which protocol is used:

```
shell> mariadb test

Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 3
Server version: 11.4.1-MariaDB MariaDB Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [test]> status;
--------------
mysql  Ver 15.1 Distrib 10.0.25-MariaDB, for Linux (x86_64) using readline 5.2

Connection id:          10
Current database:       test
Current user:           monty@localhost
...
Connection:             Localhost via UNIX socket
...
UNIX socket:            /tmp/mysql-dbug.sock
```

mariadb Commands

There are also a number of commands that can be run inside the client. Note that all text commands must be first on the line and end with a semicolon (`;`).

Command	Description
-	Enables sandbox mode until EOF (current file or the session, if interactive). From MariaDB 10.5.25, MariaDB 10.6.18, MariaDB 10.11.8, MariaDB 11.0.6, MariaDB 11.1.5, MariaDB 11.2.4, MariaDB 11.4.2.
?, ?	Synonym for `help'.
clear, \c	Clear the current input statement.
connect,	Reconnect to the server. Optional arguments are db and host.
delimiter, \d	Set statement delimiter.
edit, \e	Edit command with $EDITOR.
ego, \G	Send command to mariadb server, display result vertically.
exit, \q	Exit mariadb. Same as quit.
go, \g	Send command to mariadb server.
help, \h	Display this help.
nopager,	Disable pager, print to stdout.
noserveroutput, \o	Disables displaying of `DBMS_OUTPUT` messages. See this page for details.
notee,	Don't write into outfile.
pager, \P	Set PAGER [to_pager]. Print the query results via PAGER.
print, \p	Print current command.
prompt,	Change your mariadb prompt.
quit, \q	Quit mariadb.
rehash, #	Rebuild completion hash.
serveroutput, \O	Enables displaying of `DBMS_OUTPUT` messages. See this page for details.
source, .	Execute an SQL script file. Takes a file name as an argument. Usually looks in the working directory, unless, from MariaDB 12.0, a path is given with `--script-dir`.

Command	Description
status, \s	Get status information from the server.
system, !	Execute a system shell command. Only works in Unix-like systems.
tee, \T	Set outfile [`to_outfile`]. Append everything into given outfile.
use, \u	Use another database. Takes database name as argument.
charset, \C	Switch to another charset. Might be needed for processing binlog with multi-byte charsets.
warnings, \W	Show warnings after every statement.
nowarning, \w	Don't show warnings after every statement.

The mysql_history File

On Unix, the mariadb client writes a record of executed statements to a history file. By default, this file is named `.mysql_history` and is created in your home directory. To specify a different file, set the value of the `MYSQL_HISTFILE` environment variable.

The `.mysql_history` file should be protected with a restrictive access mode because sensitive information might be written to it, such as the text of SQL statements that contain passwords.

If you do not want to maintain a history file, first remove `.mysql_history` if it exists, and use either of the following techniques:

- Set the `MYSQL_HISTFILE` variable to `/dev/null`. To cause this setting to take effect each time you log in, put the setting in one of your shell's startup files.
- Create `.mysql_history` as a symbolic link to `/dev/null`:

```
shell> ln -s /dev/null $HOME/.mysql_history
```

You need do this only once.

prompt Command

The prompt command reconfigures the default prompt `\N [\d]>`. The string for defining the prompt can contain the following special sequences.

Option	Description
\c	A counter that increments for each statement you issue.
\D	The full current date.
\d	The default database.
\h	The server host.
\l	The current delimiter.
\m	Minutes of the current time.
\n	A newline character.
\O	The current month in three-letter format (Jan, Feb, …).
\o	The current month in numeric format.
\P	am/pm.
\p	The current TCP/IP port or socket file.
\R	The current time, in 24-hour military time (0–23).

Option	Description
\r	The current time, standard 12-hour time (1–12).
\S	Semicolon.
\s	Seconds of the current time.
\t	A tab character.
\U	Your full user_name@host_name account name.
\u	Your user name.
\v	The server version.
\w	The current day of the week in three-letter format (Mon, Tue, …).
\Y	The current year, four digits.
\y	The current year, two digits.
_	A space.
\	A space (a space follows the backslash).
’	Single quote.
”	Double quote.
\\	A literal “” backslash character.
\x	x, for any “x” not listed above.

mariadb Tips

This section describes some techniques that can help you use `mariadb` more effectively.

Displaying Query Results Vertically

Some query results are much more readable when displayed vertically, instead of in the usual horizontal table format. Queries can be displayed vertically by terminating the query with `\G` instead of a semicolon (`;`). For example, longer text values that include newlines often are much easier to read with vertical output:

```
mariadb> SELECT * FROM mails WHERE LENGTH(txt) < 300 LIMIT 300,1\G
*************************** 1. row ***************************
  msg_nro: 3068
    date: 2000-03-01 23:29:50
time_zone: +0200
mail_from: Monty
    reply: monty@no.spam.com
  mail_to: "Thimble Smith" <tim@no.spam.com>
      sbj: UTF-8
      txt: >>>>> "Thimble" == Thimble Smith writes:
Thimble> Hi.  I think this is a good idea.  Is anyone familiar
Thimble> with UTF-8 or Unicode? Otherwise, I´ll put this on my
Thimble> TODO list and see what happens.
Yes, please do that.
Regards,
Monty
    file: inbox-jani-1
    hash: 190402944
1 row in set (0.09 sec)
```

Using the –safe-updates Option

For beginners, a useful startup option is `--safe-updates` (or `--i-am-a-dummy`, which has the same effect). It is helpful for cases when you might have issued a `DELETE FROM tbl_name` statement but forgotten the `WHERE` clause.

Normally, such a statement deletes all rows from the table. With `--safe-updates`, you can delete rows only by specifying the key values that identify them. This helps prevent accidents.

When you use the `--safe-updates` option, mariadb issues the following statement when it connects to the MariaDB server:

```
SET sql_safe_updates=1, sql_select_limit=1000, sql_max_join_size=1000000;
```

The SET statement has the following effects:

- You are not allowed to execute an UPDATE or DELETE statement unless you specify a key constraint in the `WHERE` clause or provide a `LIMIT` clause (or both). For example:

```
UPDATE tbl_name SET not_key_column=val WHERE key_column=val;
UPDATE tbl_name SET not_key_column=val LIMIT 1;
```

- The server limits all large `SELECT` results to 1,000 rows unless the statement includes a `LIMIT` clause.
- The server aborts multiple-table `SELECT` statements that probably need to examine more than 1,000,000 row combinations.

To specify limits different from 1,000 and 1,000,000, you can override the defaults by using the `--select_limit` and `--max_join_size` options:

```
mariadb --safe-updates --select_limit=500 --max_join_size=10000
```

Disabling mariadb Auto-Reconnect

If the mariadb client loses its connection to the server while sending a statement, it immediately and automatically tries to reconnect once to the server and send the statement again. However, even if mariadb succeeds in reconnecting, your first connection has ended and all your previous session objects and settings are lost: temporary tables, the autocommit mode, and user-defined and session variables. Also, any current transaction rolls back. This behavior may be dangerous for you, as in the following example where the server was shut down and restarted between the first and second statements without you knowing it:

```
mariadb> SET @a=1;
Query OK, 0 rows affected (0.05 sec)
mariadb> INSERT INTO t VALUES(@a);
ERROR 2006: MySQL server has gone away
No connection. Trying to reconnect...
Connection id:    1
Current database: test
Query OK, 1 row affected (1.30 sec)
mariadb> SELECT * FROM t;
+------+
| a    |
+------+
| NULL |
+------+
```

The `@a` user variable has been lost with the connection, and after that, the reconnection it is undefined. If it is important to have mariadb terminate with an error if the connection has been lost, you can start the mariadb client with the `--skip-reconnect` option.

mysql Command-Line Client

> **Note:**
>
> The client is now called `mariadb`. The old name, `mysql`, can still be used, via a symlink in Linux, or an alternate binary in Windows.

`mysql` is a simple SQL shell with GNU readline capabilities.

This page is licensed: GPLv2

Networking Tools

See resolveip.

Resolve host names to IP addresses and the reverse with the resolveip utility, useful when configuring host-based privileges.

This page is licensed: CC BY-SA / Gnu FDL

resolveip

resolveip is a utility for resolving IP addresses to host names and vice versa.

Usage

```
resolveip [OPTIONS] hostname or IP-address
```

Options

Option	Description
Option	Description
-?, –help	Display help and exit.
-I, –info	Synonym for –help.
-s, –silent#	Be more silent.
-V, –version	Display version information and exit.

Examples

```
shell> resolveip mariadb.org
IP address of mariadb.org is 166.78.144.191
```

```
resolveip 166.78.144.191
Host name of 166.78.144.191 is mariadb.org
```

mariadb-check

Overview

`mariadb-check` is a maintenance tool that allows you to check, repair, analyze and optimize multiple tables from the command line.

> **Note:**
>
> Previously, the client was called `mysqlcheck`. It can still be accessed under this name, via a symlink in Linux, or an alternate binary in Windows.

It is essentially a command-line interface to the CHECK TABLE, REPAIR TABLE, ANALYZE TABLE, and OPTIMIZE TABLE statements, and so, unlike myisamchk and aria_chk, requires the server to be running.

> **Warning:**
>
> This tool does not work with partitioned tables.

Usage

```
./client/mariadb-check [OPTIONS] database [tables]
```

OR

```
./client/mariadb-check [OPTIONS] --databases DB1 [DB2 DB3...]
```

OR

```
./client/mariadb-check [OPTIONS] --all-databases
```

`mariadb-check` can be used to `CHECK` (`-c`, `-m`, `-C`), `REPAIR` (`-r`), `ANALYZE` (`-a`), or `OPTIMIZE` (`-o`) tables. Some of the options (like `-e` or `-q`) can be used in combination.

> **Warning:**
>
> Not all options are supported by all storage engines.

The `-c`, `-r`, `-a`, and `-o` options are exclusive to each other.

The `--check` option is used by default, if no other options were specified. You can change the default behavior by making a symbolic link to the binary, or copying it somewhere with another name, the alternatives are:

Tool	Default Option
mysqlrepair	The default option is `-r` (`--repair`).
mysqlanalyze	The default option is `-a` (`--analyze`).
mysqloptimize	The default option is `-o` (`--optimize`).

Options

`mariadb-check` supports the following options:

Option	Description
-A, –all-databases	Check all the databases. This is the same as `--databases` with all databases selected.
-1, –all-in-1	Instead of issuing one query for each table, use one query per database, naming all tables in the database in a comma-separated list.
-a, –analyze	Analyze given tables.
–auto-repair	If a checked table is corrupted, automatically fix it. Repairing is done after all tables have been checked.
–character-sets-dir=name	Directory where character set files are installed.
-c, –check	Check table for errors.
-C, –check-only-changed	Check only tables that have changed since last check or haven't been closed properly.
-g, –check-upgrade	Check tables for version-dependent changes. May be used with `--auto-repair` to correct tables requiring version-dependent updates. Automatically enables the `--fix-db-names` and `--fix-table-names` options. Used when upgrading.
–compress	Compress all information sent between the client and server if both support compression.
-B, –databases	Check several databases. Note that normally mariadb-check treats the first argument as a database name, and following arguments as table names. With this option, no tables are given, and all name arguments are regarded as database names.
## , –debug[=name]	Output debug log. Often this is `d:t:o,filename`.
–debug-check	Check memory and open file usage at exit.
–debug-info	Print some debug info at exit.
–default-auth=plugin	Default authentication client-side plugin to use.

Option	Description
–default-character-set=name	Set the default character set.
-e, –extended	Used with `--check`, it ensures that the table is fully consistent, but this takes a long time. Used with `--repair`, it forces the usage of the old, slow, repair mechanism with keycache method, instead of the much faster repair by sorting.
-F, –fast	Check only tables that haven't been closed properly.
–fix-db-names	Convert database names to the format used since MySQL 5.1. Only database names that contain special characters are affected. Used when upgrading from an old MySQL version.
–fix-table-names	Convert table names (including views) to the format used since MySQL 5.1. Only table names that contain special characters are affected. Used when upgrading from an old MySQL version.
–flush	Flush each table after check. This is useful if you don't want to have the checked tables take up space in the caches after the check.
-f, –force	Continue even if we get an SQL error.
-?, –help	Display this help message and exit.
-h name, –host=name	Connect to the given host.
-m, –medium-check	Faster than extended-check, but only finds 99.99 percent of all errors. This should be good enough for most cases.
-o, –optimize	Optimize tables.
-p, –password[=name]	Password to use when connecting to the server. If you use the short option form (`-p`), you cannot have a space between the option and the password. If you omit the password value following the `--password` or `-p` option on the command line, mariadb-check prompts for one. Specifying a password on the command line should be considered insecure. You can use an option file to avoid giving the password on the command line.
-Z, –persistent	When using `ANALYZE TABLE` (`--analyze`), it uses the `PERSISTENT FOR ALL` option, which forces Engine-independent Statistics for this table to be updated.
-W, –pipe	On Windows, connect to the server via a named pipe. This option applies only if the server supports named-pipe connections.
–plugin-dir	Directory for client-side plugins.

Option	Description
-P num, –port=num	Port number to use for connection or `0` for default to, in order of preference, `my.cnf`, `$MYSQL_TCP_PORT`, `/etc/services`, built-in default (`3306`).
–process-tables	Perform the requested operation (check, repair, analyze, optimize) on tables. Enabled by default. Use `--skip-process-tables` to disable.
–process-views[=val]	Perform the requested operation (only CHECK VIEW or REPAIR VIEW). Possible values are `NO`, `YES` (correct the checksum, if necessary, add the mariadb-version field), `UPGRADE_FROM_MYSQL` (same as `YES` and toggle the algorithm `MERGE<->TEMPTABLE`.
–protocol=name	The connection protocol (tcp, socket, pipe, memory) to use for connecting to the server. Useful when other connection parameters would cause a protocol to be used other than the one you want.
-q, –quick	If you are using this option with `CHECK TABLE`, it prevents the check from scanning the rows to check for wrong links. This is the fastest check. If you are using this option with `REPAIR TABLE`, it tries to repair only the index tree. This is the fastest repair method for a table.
-r, –repair	Can fix almost anything except unique keys that aren't unique.
–shared-memory-base-name	Shared-memory name to use for Windows connections using shared memory to a local server (started with the `--shared-memory` option). Case sensitive.
-s, –silent	Print only error messages.
–skip-database	Don't process the database (case sensitive) specified as argument.
-S name, –socket=name	For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use.
–ssl	Enables TLS. TLS is also enabled even without setting this option when certain other TLS options are set. The `--ssl` option does not enable verifying the server certificate by default. In order to verify the server certificate, you must specify the `--ssl-verify-server-cert` option.
–ssl-ca=name	Defines a path to a PEM file that should contain one or more X509 certificates for trusted Certificate Authorities (CAs) to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option implies the `--ssl` option.
–ssl-capath=name	Defines a path to a directory that contains one or more PEM files that should each contain one X509 certificate for a trusted Certificate Authority (CA) to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the openssl rehash command. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option is only supported if the client was built with OpenSSL or yaSSL. If the client was built with GnuTLS or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms. This option implies the `--ssl` option.
–ssl-cert=name	Defines a path to the X509 certificate file to use for TLS. This option requires that you use the absolute path, not a relative path. This option implies the `--ssl` option.

Option	Description
–ssl-cipher=name	List of permitted ciphers or cipher suites to use for TLS. This option implies the `--ssl` option.
–ssl-crl=name	Defines a path to a PEM file that should contain one or more revoked X509 certificates to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL or Schannel. If the client was built with yaSSL or GnuTLS, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.
–ssl-crlpath=name	Defines a path to a directory that contains one or more PEM files that should each contain one revoked X509 certificate to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the openssl rehash command. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL. If the client was built with yaSSL, GnuTLS, or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.
–ssl-key=name	Defines a path to a private key file to use for TLS. This option requires that you use the absolute path, not a relative path. This option implies the `--ssl` option.
–ssl-verify-server-cert	Enables server certificate verification. This option is disabled by default.
–tables	Overrides the `--databases` or `-B` option such that all name arguments following the option are regarded as table names.
–use-frm	For repair operations on MyISAM tables, get table structure from .frm file, so the table can be repaired even if the .MYI header is corrupted.
-u, –user=name	User for login if not current user.
-v, –verbose	Print info about the various stages. You can give this option several times to get even more information. See mariadb-check and verbose, below.
-V, –version	Output version information and exit.
–write-binlog	Write `ANALYZE`, `OPTIMIZE`, and `REPAIR TABLE` statements to the binary log. Enabled by default; use `--skip-write-binlog` when commands should not be sent to replication slaves.

Option Files

In addition to reading options from the command line, `mariadb-check` can also read options from option files. If an unknown option is provided to `mariadb-check` in an option file, it is ignored.

The following options relate to how MariaDB command line tools handles option files. They must be given as the first argument on the command line:

Option	Description
–print-defaults	Print the program argument list and exit.
–no-defaults	Don't read default options from any option file.
–defaults-file=#	Only read default options from the given file `#`.

Option	Description
–defaults-extra-file=#	Read this file after the global files are read.
–defaults-group-suffix=#	In addition to the default option groups, also read option groups with this suffix.

`mariadb-check` is linked with MariaDB Connector/C. However, MariaDB Connector/C does not yet handle the parsing of option files for this client. That is still performed by the server option file parsing code. See MDEV-19035 for more information.

Option Groups

`mariadb-check` reads options from the following option groups from option files:

Group	Description
[mysqlcheck]	Options read by mysqlcheck, which includes both MariaDB Server and MySQL Server.
[mariadb-check]	Options read by mariadb-check.
[client]	Options read by all MariaDB and MySQL client programs, which includes both MariaDB and MySQL clients. For example, mysqldump.
[client-server]	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients.
[client-mariadb]	Options read by all MariaDB client programs.

Notes

Default Values

To see the default values for the options and the arguments you get from configuration files, you can do:

```
./client/mariadb-check --print-defaults
./client/mariadb-check --help
```

mariadb-check and auto-repair

When running `mariadb-check` with `--auto-repair` (as done by mariadb-upgrade), `mariadb-check` will first check all tables and then in a separate phase repair those that failed the check.

mariadb-check and all-databases

`mariadb-check --all-databases` will ignore the internal log tables general_log and slow_log as these can't be checked, repaired or optimized.

mariadb-check and verbose

Using one `--verbose` option will give you more information about what mariadb-check is doing.

Using two `--verbose` options will also give you connection information.

If you use three `--verbose` options you will also get, on stdout, all ALTER, RENAME, and CHECK commands that mariadb-check executes.

Sequences

From MariaDB 12.0, `mariadb-check` supports sequences.

This page is licensed: CC BY-SA / Gnu FDL

mariadb-convert-table-format

`mariadb-convert-table-format` converts the tables in a database to use a particular storage engine (MyISAM by default).

> **Note:**
>
> Previously, the client was called `mysql_convert_table_format`. It can still be accessed under this name, via a symlink in Linux, or an alternate binary in Windows.

Usage

```
mariadb-convert-table-format [options] db_name
```

Description

`mariadb-convert-table-format` is written in Perl and requires that the DBI and DBD::mysql Perl modules be installed. Invoke `mariadb-convert-table-format` like this:

```
shell> mariadb-convert-table-format [options]db_name
```

The `db_name` argument indicates the database containing the tables to be converted.

Options

`mariadb-convert-table-format` supports the options described in the following list:

Option	Description
-?, –help	Display help and exit.
-e, –engine=ENGINE	Specify the storage engine that the tables should be converted to use. The default is MyISAM if this option is not given.
-f, –force	Continue even if errors occur.
-h, –host=host_name	Connect to the MariaDB server on the given host. Default localhost.
-p, –password=password	The password to use when connecting to the server. Note that the password value is not optional for this option, unlike for other client programs. Specifying the password on the command line is generally considered insecure.
-P, –port=port_num	The TCP/IP port number to use for the connection.
-S, –socket=path	For connections to localhost, the Unix socket file to use.
-u, –user=user_name	The MariaDB user name to use when connecting to the server.
-v, –verbose	Verbose mode. Print more information about what the program does.
-V, –version	Display version information and exit.

This page is licensed: CC BY-SA / Gnu FDL

mariadb-fix-extensions

`mariadb-fix-extensions` converts the extensions for MyISAM (or ISAM) table files to their canonical forms.

> **Note:**
>
> Previously, the client was called `mysql_fix_extensions`. It can still be accessed under this name, via a symlink in Linux, or an alternate binary in Windows.

It looks for files with extensions matching any lettercase variant of `.frm`, `.myd`, `.myi`, `.isd`, and `.ism` and renames them to have extensions of `.frm`, `.MYD`, `.MYI`, `.ISD`, and `.ISM`, respectively. This can be useful after transferring the files from a system with case-insensitive file names (such as Windows) to a system with case-sensitive file names.

Invoke `mariadb-fix-extensions` as follows, where `data_dir` is the path name to the MariaDB data directory:

```
mariadb-fix-extensions data_dir
```

Testing Tools

See mariadb-slap.

Load-test MariaDB with mariadb-slap by emulating many concurrent clients running a set of queries repeatedly (formerly mysqlslap).

See mariadb-stress-test.

Stress-test a MariaDB server by running test scenarios repeatedly with mariadb-stress-test (a symlink to mysql-stress-test).

See mariadb-test.

MariaDB uses mariadb-test to test functionality. It is an all-in-one test framework doing unit, regression, and conformance testing

This page is licensed: CC BY-SA / Gnu FDL

mariadb-slap

`mariadb-slap` is a tool for load-testing MariaDB. It allows you to emulate multiple concurrent connections, and run a set of queries multiple times.

Prior to MariaDB 10.5, the client was called `mysqlslap`. It can still be accessed under this name, via a symlink in Linux, or an alternate binary in Windows.

It returns a benchmark including the following information:

- Average number of seconds to run all queries;
- Minimum number of seconds to run all queries;
- Maximum number of seconds to run all queries;
- Number of clients running queries;
- Average number of queries per client.

Using mariadb-slap

The command to use `mariadb-slap` and the general syntax is:

```
mariadb-slap [options]
```

Options

`mariadb-slap` supports the following options:

Option	Description
-a, –auto-generate-sql	Generate SQL statements automatically when they are not supplied in files or via command options.
–auto-generate-sql-add-autoincrement	Add an AUTO_INCREMENT column to auto-generated tables.
–auto-generate-sql-execute-number=num	Specify how many queries to generate automatically.
–auto-generate-sql-guid-primary	Add GUID based primary keys to auto-generated tables.
–auto-generate-sql-load-type=name	Specify the test load type. The allowable values are read (scan tables), write (insert into tables), key (read primary keys), update (update primary keys), or mixed (half inserts, half scanning selects). The default is mixed.
–auto-generate-sql-secondary-indexes=num	Number of secondary indexes to add to auto-generated tables. By default, none are added.
–auto-generate-sql-unique-query-number=num	Number of unique queries to generate for automatic tests. For example, if you run a key test that performs 1000 selects, you can use this option with a value of 1000 to run 1000 unique queries, or with a value of 50 to perform 50 different selects. The default is 10.
–auto-generate-sql-unique-write-number=num	Number of unique queries to generate for auto-generate-sql-write-number.
–auto-generate-sql-write-number=num	Number of row inserts to perform for each thread. The default is 100.

Option	Description
–commit=num	Number of statements to execute before committing. The default is 0.
-C, –compress	Use compression in server/client protocol if both support it.
-c name, –concurrency=name	Number of clients to simulate for query to run.
–create=name	File or string containing the statement to use for creating the table.
–create-schema=name	Schema to run tests in.
–csv[=name]	Generate comma-delimited output to named file or to standard output if no file is named.
-d, –debug[=options]	For debug builds, write a debugging log. A typical debug_options string is d:t:o,file_name. The default is d:t:o,/tmp/mariadb-slap.trace.
–debug-check	Check memory and open file usage at exit.
-T, –debug-info	Print some debug info at exit.
–default-auth=name	Default authentication client-side plugin to use.
–defaults-extra-file=name	Read this file after the global files are read. Must be given as the first option.
–defaults-file=name	Only read default options from the given file name Must be given as the first option.
-F name, –delimiter=name	Delimiter to use in SQL statements supplied in file or command line.
–detach=num	Detach (close and reopen) connections after the specified number of requests. The default is 0 (connections are not detached).
-e name, –engine=name	Comma separated list of storage engines to use for creating the table. The test is run for each engine. You can also specify an option for an engine after a #:#, for example memory:max_row=2300.
-?, –help	Display help and exit.
-h name, –host=name	Connect to the MariaDB server on the given host.
–init-command=name	SQL Command to execute when connecting to the MariaDB server. Will automatically be re-executed when reconnecting.

Option	Description
-i num, –iterations=num	Number of times to run the tests.
–no-defaults	Don’t read default options from any option file. Must be given as the first option.
–no-drop	Do not drop any schema created during the test after the test is complete.
-x name, –number-char-cols=name	Number of VARCHAR columns to create in table if specifying –auto-generate-sql.
-y name, –number-int-cols=name	Number of INT columns to create in table if specifying –auto-generate-sql.
–number-of-queries=num	Limit each client to approximately this number of queries. Query counting takes into account the statement delimiter. For example, if you invoke as follows, mariadb-slap –delimiter=“;” –number-of-queries=10 –query=“use test;insert into t values(null)”, the #; delimiter is recognized so that each instance of the query string counts as two queries. As a result, 5 rows (not 10) are inserted.
–only-print	Do not connect to the databases, but instead print out what would have been done.
-p[password], –password[=password]	Password to use when connecting to server. If password is not given it’s asked from the command line. Specifying a password on the command line should be considered insecure. You can use an option file to avoid giving the password on the command line.
-W, –pipe	On Windows, connect to the server via a named pipe. This option applies only if the server supports named-pipe connections.
–plugin-dir=name	Directory for client-side plugins.
-P num, –port=num	Port number to use for connection.
–post-query=name	Query to run or file containing query to execute after tests have completed. This execution is not counted for timing purposes.
–post-system=name	system() string to execute after tests have completed. This execution is not counted for timing purposes.
–pre-query=name	Query to run or file containing query to execute before running tests. This execution is not counted for timing purposes.
–pre-system=name	system() string to execute before running tests. This execution is not counted for timing purposes.
–print-defaults	Print the program argument list and exit. Must be given as the first option.
–protocol=name	The protocol to use for connection (tcp, socket, pipe, memory).

Option	Description
-q name, –query=name	Query to run or file containing query to run.
–shared-memory-base-name	Shared-memory name to use for Windows connections using shared memory to a local server (started with the –shared-memory option). Case-sensitive.
-s, –silent	Run program in silent mode - no output.
-S, –socket=name	For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use.
–ssl	Enables TLS. TLS is also enabled even without setting this option when certain other TLS options are set. The –ssl option will not enable verifying the server certificate by default. In order to verify the server certificate, the user must specify the –ssl-verify-server-cert option.
–ssl-ca=name	Defines a path to a PEM file that should contain one or more X509 certificates for trusted Certificate Authorities (CAs) to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option implies the –ssl option.
–ssl-capath=name	Defines a path to a directory that contains one or more PEM files that should each contain one X509 certificate for a trusted Certificate Authority (CA) to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the openssl rehash command. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option is only supported if the client was built with OpenSSL or yaSSL. If the client was built with GnuTLS or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms. This option implies the –ssl option.
–ssl-cert=name	Defines a path to the X509 certificate file to use for TLS. This option requires that you use the absolute path, not a relative path. This option implies the –ssl option.
–ssl-cipher=name	List of permitted ciphers or cipher suites to use for TLS. This option implies the –ssl option.
–ssl-crl=name	Defines a path to a PEM file that should contain one or more revoked X509 certificates to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL or Schannel. If the client was built with yaSSL or GnuTLS, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.
–ssl-crlpath=name	Defines a path to a directory that contains one or more PEM files that should each contain one revoked X509 certificate to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the openssl rehash command. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL. If the client was built with yaSSL, GnuTLS, or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.
–ssl-key=name	Defines a path to a private key file to use for TLS. This option requires that you use the absolute path, not a relative path. This option implies the –ssl option.
–ssl-verify-server-cert	Enables server certificate verification. This option is disabled by default.
-u, –user=name	User for login if not current user.
-v, –verbose	More verbose output; you can use this multiple times to get even more verbose output.

Option	Description
-V, –version	Output version information and exit.

Option Files

In addition to reading options from the command line, `mariadb-slap` can also read options from option files. If an unknown option is provided to `mariadb-slap` in an option file, then it is ignored.

The following options relate to how MariaDB command line tools handles option files. They must be given as the first argument on the command line:

Option	Description
–print-defaults	Print the program argument list and exit.
–no-defaults	Don't read default options from any option file.
–defaults-file=#	Only read default options from the given file #.
–defaults-extra-file=#	Read this file after the global files are read.
–defaults-group-suffix=#	In addition to the default option groups, also read option groups with this suffix.

`mariadb-slap` is linked with MariaDB Connector/C. However, MariaDB Connector/C does not yet handle the parsing of option files for this client. That is still performed by the server option file parsing code. See MDEV-19035 for more information.

Option Groups

`mariadb-slap` reads options from the following option groups from option files:

Group	Description
[mysqlslap]	Options read by mariadb-slap, which includes both MariaDB Server and MySQL Server.
[mariadb-slap]	Options read by mariadb-slap. Available starting with MariaDB 10.4.6.
[client]	Options read by all MariaDB and MySQL client programs, which includes both MariaDB and MySQL clients. For example, mysqldump.
[client-server]	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients.
[client-mariadb]	Options read by all MariaDB client programs.

Examples

Create a table with data, and then query it with 40 simultaneous connections 100 times each.

```
mariadb-slap
 --delimiter=";"
 --create="CREATE TABLE t (a int);INSERT INTO t VALUES (5)"
 --query="SELECT * FROM t"
 --concurrency=40
 --iterations=100

Benchmark
    Average number of seconds to run all queries: 0.010 seconds
    Minimum number of seconds to run all queries: 0.009 seconds
    Maximum number of seconds to run all queries: 0.020 seconds
    Number of clients running queries: 40
    Average number of queries per client: 1
```

Using files to store the create and query SQL. Each file can contain multiple statements separated by the specified delimiter.

```
mariadb-slap
 --create=define.sql
 --query=query.sql
 --concurrency=10
 --iterations=20
 --delimiter=";"

Benchmark
    Average number of seconds to run all queries: 0.002 seconds
    Minimum number of seconds to run all queries: 0.002 seconds
    Maximum number of seconds to run all queries: 0.004 seconds
    Number of clients running queries: 10
    Average number of queries per client: 1
```

mariadb-stress-test

`mariadb-stress-test` is a symlink to `mysql-stress-test`, the script for assisting with adding users or databases or changing passwords in MariaDB.

> **CURRENT**
>
> `mysql-stress-test` is the symlink, and `mariadb-stress-test` the binary name.
>
> **< 10.5.2**
>
> `mysql-stress-test` is the binary name.

mariadb-stress-test.pl is a Perl script that performs stress-testing of the MariaDB server. It requires a version of Perl that has been built with threads support.

Syntax

```
mariadb-stress-test.pl [options]
```

Options

Option	Description
–help	Display a help message and exit.
–abort-on-error=N	Causes the program to abort if an error with severity less than or equal to N was encountered. Set to 1 to abort on any error.
–check-tests-file	Periodically check the file that lists the tests to be run. If it has been modified, reread the file. This can be useful if you update the list of tests to be run during a stress test.
–cleanup	Force cleanup of the working directory.
–log-error-details	Log error details in the global error log file.
–loop-count=N	In sequential test mode, the number of loops to execute before exiting.
–mysqltest=path	The path name to the mysqltest program.

Option	Description
–server-database=db_name	The database to use for the tests. The default is test.
–server-host=host_name	he host name of the local host to use for making a TCP/IP connection to the local server. By default, the connection is made to localhost using a Unix socket file.
–server-logs-dir=path	This option is required. path is the directory where all client session logs is stored. Usually this is the shared directory that is associated with the server used for testing.
–server-password=password	The password to use when connecting to the server.
–server-port=port_num	The TCP/IP port number to use for connecting to the server. The default is 3306.
–server-socket=file_name	For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use. The default is /tmp/mysql.sock.
–server-user=user_name	The MariaDB user name to use when connecting to the server. The default is root.
–sleep-time=N	The delay in seconds between test executions.
–stress-basedir=path	This option is required and specified the path is the working directory for the test run. It is used as the temporary location for result tracking during testing.
–stress-datadir=path	The directory of data files to be used during testing. The default location is the data directory under the location given by the –stress-suite-basedir option.
–stress-init-file[=path]	file_name is the location of the file that contains the list of tests to be run once to initialize the database for the testing. If missing, the default file is stress_init.txt in the test suite directory.
–stress-mode=mode	This option indicates the test order in stress-test mode. The mode value is either random to select tests in random order or seq to run tests in each thread in the order specified in the test list file. The default mode is random.
–stress-suite-basedir=path	This option is required and specifies the directory that has the t and r subdirectories containing the test case and result files. This directory is also the default location of the stress-test.txt file that contains the list of tests. (A different location can be specified with the –stress-tests-file option.)
–stress-tests-file[=file_name]	Use this option to run the stress tests. file_name is the location of the file that contains the list of tests. If omitted, the default file is stress-test.txt in the stress suite directory. (See –stress-suite-basedir.)
–suite=suite_name	Run the named test suite. The default name is main (the regular test suite located in the mysql-test directory).
–test-count=N	The number of tests to execute before exiting.
–test-duration=N	The duration of stress testing in seconds.
–threads=N	The number of threads. The default is 1.
–verbose	Verbose mode. Print more information about what the program does

mariadb-test Overview

Basics

The client program `mariadb-test` executes a *test file* and compares the produced output with the *result file*. If the files match, the test is passed; otherwise, the test has failed. This approach can be used to test any SQL statement, as well as other executables (with the `exec` command).

The complete process of testing is governed and monitored by the *mariadb-test-run.pl* driver script, or *mtr* for short (for convenience, `mtr` is created as a symbolic link to `mariadb-test-run.pl`). The `mtr` script is responsible for preparing the test environment, creating a list of all tests to run, running them, and producing the report at the end. It can run many tests in parallel, execute tests in an order which minimizes server restarts (as they are slow), run tests in a debugger or under `valgrind` or `strace`, and so on.

Test files are located in *suites*. A *suite* is a directory which contains test files, result files, and optional configuration files. The `mtr` script looks for suites in the `mariadb-test/suite` directory, and in the `mariadb-test` subdirectories of plugins and storage engine directories. For example, the following are all valid suite paths:

```
mariadb-test/suite/rpl
```

```
mariadb-test/suite/handler
```

```
storage/example/mariadb-test/demo
```

```
plugin/auth_pam/mariadb-test/pam
```

In almost all cases, the suite directory name is the suite name. A notable historical exception is the *main* suite, which is located directly in the `mariadb-test` directory.

Test files have a `.test` extension and can be placed directly in the suite directory (for example, `mariadb-test/suite/handler/interface.test`) or in the `t` subdirectory (e.g. `mariadb-test/suite/rpl/t/rpl_alter.test` or `mariadb-test/t/grant.test`). Similarly, result files have the `.result` extension and can be placed either in the suite directory or in the `r` subdirectory.

A test file can include other files (with the `source` command). These included files can have any name and may be placed anywhere, but customarily they have a `.inc` extension and are located either in the suite directory or in the `inc` or `include` subdirectories (for example, `mariadb-test/suite/handler/init.inc` or `mariadb-test/include/start_slave.inc`).

Other files which affect testing, while not being tests themselves, are:

- `disabled.def`
- `suite.opt`
- other `*.opt` files
- `my.cnf`
- other `*.cnf` files
- `combinations`
- other `*.combinations` files
- `suite.pm`
- `*.sh` files
- `*.require` files
- `*.rdiff` files
- `valgrind.supp`

See Auxiliary files for details on these.

Overlays

In addition to regular suite directories, `mtr` supports *overlays*. An *overlay* is a directory with the same name as an existing suite, but which is located in a storage engine or plugin directory. For example, `storage/myisam/mariadb-test/rpl` could be a *myisam* overlay of the *rpl* suite in `mariadb-test/suite/rpl`.
And `plugin/daemon_example/mariadb-test/demo` could be a *daemon_example* overlay of the *demo* suite in `storage/example/mariadb-test/demo`. As a special exception, an overlay of the main suite, should be called `main`, as in `storage/pbxt/mariadb-test/main`.

An overlay is like a second transparent layer in a graphics editor. It can obscure, extend, or modify the background image. Also, one may notice that an overlay is very close to a *UnionFS*, but implemented in perl inside `mtr`.

An overlay can replace almost any file in the overlaid suite, or add new files. For example, if some overlay of the main suite contains a `include/have_innodb.inc` file, then all tests that include it will see and use the overlaid version. Or, an overlay can create a `t/create.opt` file (even though the main suite does not have such a file), and `create.test` is executed with the specified additional options.

But adding an overlay never affects how the original suite is executed. That is, `mtr` always executes the original suite as if no overlay was present. Additionally, it executes a combined “union” of the overlay and the original suite. When doing that, `mtr` takes care to avoid re-executing tests that are not changed in the overlay. For example, creating `t/create.opt` in the overlay of the main suite will only cause `create.test` to be executed in the overlay. But creating `suite.opt` affects all tests — and it will cause all tests to be re-executed with the new options.

Combinations

In certain cases it makes sense to run a specific test or a group of tests several times with different server settings. This can be done using so-called *combinations*. Combinations are groups of settings that are used alternatively. A

combinations file defines these alternatives using `my.cnf` syntax, for example:

```
[row]
binlog-format=row
[stmt]
binlog-format=statement
[mix]
binlog-format=mixed
```

All tests where this combinations file applies is run three times: Once for the combination called “row”, and `--binlog-format=row` on the server command line, once for the “stmt” combination, and once for the “mix” combination.

More than one combinations file may be applicable to a given test file. In this case, `mtr` runs the test for all possible combinations of the given combinations. A test that uses replication (three combinations as above) and InnoDB (two combinations - innodb and xtradb), is run six times.

Sample Output

The typical `mtr` output looks like this:

```
==========================================================================
TEST                                WORKER RESULT   TIME (ms) or COMMENT
--------------------------------------------------------------------------
rpl.rpl_row_find_row_debug               [ skipped ]  Requires debug build
main-pbxt.connect                        [ skipped ]  No PBXT engine
main-pbxt.mysqlbinlog_row                [ disabled ]  test expects a non-transactional engine
rpl.rpl_savepoint 'mix,xtradb'           w2 [ pass ]    238
rpl.rpl_stm_innodb 'innodb_plugin,row'   w1 [ skipped ]  Neither MIXED nor STATEMENT binlog format
binlog.binlog_sf 'stmt'                  w2 [ pass ]      7
unit.dbug                                w2 [ pass ]      1
maria.small_blocksize                    w1 [ pass ]     23
sys_vars.autocommit_func3 'innodb_plugin' w1 [ pass ]      5
sys_vars.autocommit_func3 'xtradb'       w1 [ pass ]      6
main.ipv6                                w1 [ pass ]    131
...
```

Every test is printed as “suitename.testname”, and a suite name may include an overlay name (like in `main-pbxt`). After the test name, `mtr` prints combinations that were applied to this test, if any.

A similar syntax can be used on the `mtr` command line to specify what tests to run:

$ ./mtr innodb	**$ ./mtr main.innodb**
$ ./mtr innodb	search for innodb test in every suite from the default list, and run all that was found.
$ ./mtr main.innodb	run the innodb test from the main suite
$ ./mtr main-pbxt.innodb	run the innodb test from the pbxt overlay of the main suite
$ ./mtr main-.innodb	run the innodb test from the main suite and all its overlays.
$ ./mtr main.innodb,xtradb	run the innodb test from the main suite, only in the xtradb combination
$ ./mtr –suite=rpl	Run all test in the rpl suite (found in the suite/rpl directory)
$ ./mtr –suite=mroonga/storage	Run all test in the mroonga/wrapper suite (found in the storage/mroonga/mysql-test/mroonga/storage directory)

Plugin Support

The `mtr` driver has special support for MariaDB plugins.

First, on startup it copies or symlinks all dynamically-built plugins into `var/plugins`. This allows one to have many plugins loaded at the same time. For example, you can load Federated and InnoDB engines together. Also, `mtr`

creates environment variables for every plugin with the corresponding plugin name. For example, if the InnoDB engine was built, `$HA_INNODB_SO` is set to `ha_innodb.so` (or `ha_innodb.dll` on Windows). The test can safely use the corresponding environment variable on all platforms to refer to a plugin file; it always has the correct platform-dependent extension.

Second, when combining server command line options (which may come from many different sources) into one long list before starting `mariadbd`, mtr treats `--plugin-load` specially. Normal server semantics is to use the latest value of any particular option on the command line. If one starts the server with, for example, `--port=2000 --port=3000`, the server will use the last value for the port, that is 3000. To allow different `.opt` files to require different plugins, mtr goes through the assembled server command line, and joins all `--plugin-load` options into one. Additionally it removes all empty `--plugin-load` options. For example, suppose a test is affected by three `.opt` files which contain, respectively:

```
--plugin-load=$HA_INNODB_SO
```

```
--plugin-load=$AUTH_PAM_SO
```

```
--plugin-load=$HA_EXAMPLE_SO
```

Assuming the Example engine was not built (`$HA_EXAMPLE_SO` is empty), the server gets this:

```
--plugin-load=ha_innodb.so:auth_pam.so
```

Instead of this:

```
--plugin-load=ha_innodb.so --plugin-load=auth_pam.so --plugin-load=
```

Third, to allow plugin sources to be simply copied into the `plugin/` or `storage/` directories, and still not affect existing tests (even if new plugins are statically linked into the server), mtr automatically disables all optional plugins on server startup. A plugin is optional if it can be disabled with the corresponding `--skip-XXX` server command line option. Mandatory plugins, like MyISAM or MEMORY, do not have `--skip-XXX` options (for instance, there is no `--skip-myisam` option). This `mtr` behavior means that no plugin, statically or dynamically built, has any effect on the server unless it was explicitly enabled. A convenient way to enable a given plugin *XXX* for specific tests is to create a `have_XXX.opt` file which contains the necessary command line options, and a `have_XXX.inc` file which checks whether a plugin was loaded. Then any test that needs this plugin can source the `have_XXX.inc` file and have the plugin loaded automatically.

mtr Communication Procedure

`mtr` is first creating the server socket (`master`). After that, `workers` are created using `fork()`.

For each worker, the `run_worker()` function is called, which is executing the following:

- Creates a new socket to connect to `server_port` obtained from the `master`.
- Initiate communication with the `master` using `START` command.
- `master` sends first test from list of tests supplied by the user and immediately sends command `TESTCASE` to the `worker`.
- `worker` gets command `TESTCASE` and processes test case, by calling `run_testcase()` function which starts(/restarts if needed) the server and sends `TESTRESULT` (in case of restart `WARNINGS` command is issued to the `master` in case some warnings/error logs are found).
- `master` accepts `TESTRESULT` command and run `mtr_report_test()` function which check does the test fail and also generates the new command `TESTCASE` if some new test case exist.

- If there is no other test case `master` sends `BYE` command which gets accepted by the `worker` which is properly closing the connection.

Options

From MariaDB Server 11.8.3, you can start `mtr` with the `--enable_serveroutput` option to enable `DBMS_OUTPUT` messages. Disable displaying those messages with `--disable_serveroutput`. See this page for details.

A new package procedure was added, `DBMS_OUTPUT.GET_LINES_RESULT()`. It reuses the SQL code fetching lines from the `DBMS_OUTPUT` buffer. All buffer lines are returned in a single result set. This procedure is MariaDB-specific; it does not exist in Oracle. This workaround is needed in MariaDB, instead of using the `GET_LINES()` function, because MariaDB does not support fetching arrays in the client-server protocol.

Installing MinIO for Usage With mariadb-test-run

When testing the S3 storage engine with the s3 test suite, mariadb-test-run needs access to Amazon S3 compatible storage.

The easiest way to achieve this is to install MinIO, an open source S3 compatible storage.

Here is a shell script that you can use to install MinIO with the right credentials for mariadb-test-run.
This should work on most Linux systems as the binaries are statically linked.
You can alternatively download MinIO binaries directly from here.

```
# Where to install the MinIO binaries and where to store the data
install=/my/local/minio
data=/tmp/shared

# Get the MinIO binaries. You can skip this test if you already have MinIO installed.
mkdir -p $install
wget https://dl.min.io/server/minio/release/linux-amd64/minio -O $install/minio
wget https://dl.min.io/client/mc/release/linux-amd64/mc -O $install/mc
chmod a+x $install/minio $install/mc

# Setup MinIO for usage with mariadb-test-run
MINIO_ACCESS_KEY=minio MINIO_SECRET_KEY=minioadmin $install/minio server $data 2>&1 &
$install/mc config host add local http://127.0.0.1:9000 minio minioadmin
$install/mc mb --ignore-existing local/storage-engine
```

Now you can run the S3 test suite:

```
cd "mysql-source-dir"/mariadb-test
./mariadb-test-run --suite=s3
```

If there is an issue while running the test suite, you can see the files created by MinIO with:

```
$install/mc ls -r local/storage-engine
```

or

```
ls $data/storage-engine
```

If you want to use MinIO with different credentials or you want to run the test against another S3 storage you ave to update the update the following files:

```
mariadb-test/suite/s3/my.cnf
mariadb-test/suite/s3/slave.cnf
```

This page is licensed: CC BY-SA / Gnu FDL

mariadb-test Auxiliary Files

The mariadb-test framework utilizes many other files that affect the testing process, in addition to test and result files.

`disabled.def` file

This file can be used to disable certain tests temporarily. For example, if one test fails and you are working on that, you may want to push the changeset that disables the test into the test suite so that other tests won't be disturbed by this failure.

The file contains test names and a comment (that should explain why the test was disabled), separated by a colon. Lines that start with a hash sign
(`#`) are ignored. A typical `disabled.def` may look like this (note that a hash sign in the middle of a line does not start a comment):

```
# List of disabled tests
# test name : comment
rpl_redirect : Fails due to bug#49978
events_time_zone  : need to fix the timing
```

During testing, mtr will print disabled tests like this:

```
...
rpl.rpl_redirect              [ disabled ]  Fails due to bug#49978
rpl.events_time_zone          [ disabled ]  need to fix the timing
...
```

This file should be located in the suite directory.

`suite.opt` file

This file lists server options that is added to the `mariadbd` command line for every test of this suite. It can refer to environment variables with the `$NAME` syntax. Shell meta-characters should be quoted. For example

```
--plugin-load=$AUTH_PAM_SO
--max-connections=40 --net_read_timeout=5
"--replicate-rewrite-db=test->rewrite"
```

Note that options may be put either on one line or on separate lines. It is a good idea to start an option name with the `--loose-` prefix if the server may or may not recognize the option depending on the configuration.
An unknown option in the `.opt` file will stop the server from starting, and the test is aborted.

This file should be located in the suite directory.

other `*.opt` files

For every test or include file `somefile.test` or `somefile.inc`, mtr will look for `somefile.opt`, `somefile-master.opt` and `somefile-slave.opt`.
These files have exactly the same syntax as the `suite.opt` above. Options from these files will also be added to the server command line (all servers started for this test, only master, or only slave respectively) for all affected tests, for example, for all tests that include `somefile.inc` directly or indirectly.

A typical usage example is `include/have_blackhole.inc` and `include/have_blackhole.opt`. The latter contains the necessary command line options to load the Blackhole storage engine, while the former verifies that the engine

was really loaded. Any test that needs the Blackhole engine needs only to start from `source include/have_blackhole.inc;` and the engine will be automatically loaded for the test.

`my.cnf` file

This is not the `my.cnf` file that tests from this suite will use, but rather a *template* of it. It is converted later to an actual `my.cnf`. If a suite contains no `my.cnf` template, a default template,
— `include/default_my.cnf`
— is used. Or `suite/rpl/my.cnf` if the test includes `master-slave.inc` (it's one of the few bits of the old MySQL `mysql-test-run` magic that we have not removed yet). Typically a suite template will not contain a complete server configuration, but rather start from

```
!include include/default_my.cnf
```

and then add the necessary modifications.

The syntax of `my.cnf` template is the same of a normal `my.cnf` file, with a few extensions and assumptions. They are:

- For any group with the name `[mysqld.N]`, where N is a number, mtr will start one `mysqld` process. Usually one needs to have only `[mysqld.1]` group, and `[mysqld.2]` group for replication tests.
- There can be groups with non-standard names (`[foo]`, `[bar]`, whatever), not used by `mysqld`. The `suite.pm` files (see below) may use them somehow.
- Values can refer to each other using the syntax `@groupname.optionname`
  — these references be expanded as needed. For example

```
[mysqld.2]
master-port= @mysqld.1.port
```

- it sets the value of the `master-port` in the `[mysqld.2]` group to the value of `port` in the `[mysqld.1]` group.
- An option name may start with a hash sign `#`. In the resulting `my.cnf` it will look like a comment, but it still can be referred to. For example:

```
[example]
#location = localhost:@mysqld.1.port
bar = server:@example.#location/data
```

- There is the `[ENV]` group. It sets values for the environment variables.
  For example

```
[ENV]
MASTER_MYPORT = @mysqld.1.port
```

- Also, one can refer to values of environment variables via this group:

```
[mysqld.1]
user = @ENV.LOGNAME
```

- There is the `[OPT]` group. It allows to invoke functions and generate values. Currently it contains only one option
  — `@OPT.port`. Every time this option is referred to in some other group in the `my.cnf` template, a new unique port number is generated. It will not match any other port number used by this test run.
  For example

```
[ENV]
SPHINXSEARCH_PORT = @OPT.port
```

This file should be located in the suite directory.

other `*.cnf` files

For every test file `somefile.test` (but for not included files) mtr will look for `somefile.cnf` file. If such a file exists, it is used as a template instead of suite `my.cnf` or a default `include/default_my.cnf` templates.

`combinations` file

The `combinations` file defines few sets of alternative configurations, and every test in this suite is run many times - once for every configuration.
This can be used, for example, to run all replication tests in the *rpl* suite for all three binlog format modes (row, statement, and mixed). A corresponding `combinations` file would look as following:

```
[row]
binlog-format=row

[stmt]
binlog-format=statement

[mix]
binlog-format=mixed
```

It uses `my.cnf` file syntax, with groups (where group names define combination names) and options. But, despite the similarity, it is not a `my.cnf` template, and it cannot use the templating extensions. Instead, options from the `combinations` file are added to the server command line. In this regard, combination file is closer to `suite.opt` file. And just like it, combination file can use environment variables using the `$NAME` syntax.

Not all tests will necessarily run for all combinations. A particular test may require to be run only in one specific combination. For example, in replication, if a test can only be run with the row binlog format, it will have `--binlog-format=row` in one of the `.opt` files. In this case, mtr will notice that server command line already has an option that matches one of the combinations, and will skip all other combinations for this particular test.

The `combinations` file should be located in the suite directory.

other `*.combinations` files

Just like with the `*.opt` files, mtr will use `somefile.combinations` file for any `somefile.test` and `somefile.inc` that is used in testing. These files have exactly the same format as a suite `combinations` file.

This can cause many combination files affecting one test file (if a test includes two `.inc` files, and both of them have corresponding `.combinations` files). In this case, mtr will run the test for all combinations of combinations from both files. In MariaDB 5.5, for example, `rpl_init.inc` adds combinations for row/statement/mixed, and `have_innodb.inc` adds combinations for innodb/xtradb. Thus any replication test that uses innodb is run six times.

`suite.pm` file

This (optional) file is a perl module. It must declare a package that inherits from `My::Suite`.

This file must normally end with `bless {}` — that is it must return an object of that class. It can also return a string — in this case all tests in the suite is skipped, with this string being printed as a reason (for example “PBXT engine was not compiled”).

A suite class can define the following methods:

- `config_files()`
- `is_default()`
- `list_cases()`
- `servers()`
- `skip_combinations()`
- `start_test()`

A `config_files()` method returns a list of additional config files (besides `my.cnf`), that this suite needs to be created. For every file it specifies a function that will create it, when given a `My::Config` object. For example:

```
sub config_files {(
    'config.ini' => \&write_ini,
    'new.conf'   => \&do_new
)}
```

A `servers()` method returns a list of processes that needs to be started for this suite. A process is specified as a [regex, hash] pair. The regular expression must match a section in the `my.cnf` template (for example, `qr/mysqld\./` corresponds to all `mysqld` processes), the hash contains these options:

SORT	a number. Processes are started in the order of increasing SORT values (and stopped in the reverse order). mysqld has number 300.
START	a function to start a process. It takes two arguments, My::Config::Group and My::Test. If START is undefined a process will not be started.
WAIT	a function to wait for the process to be started. It takes My::Config::Group as an argument. Internally mtr first invokes START for all processes, then WAIT for all started processes.

```
sub servers {(
    qr/^foo$/ => { SORT => 200,  # start foo before mysqld
                   START => \&start_foo,
                   WAIT => \&wait_foo }
)}
```

See the *sphinx* suite for a working example.

A `list_cases()` method returns a complete list of tests for this suite. By default it is the list of files that have `.test` extension, but without the extension. This list is filtered by mtr, subject to different mtr options (`--big-test`, `--start-from`, etc), the suite object does not have to do it.

A `start_test()` method starts one test process, by default it is `mariadb-test`. See the *unit* suite for a working example of `list_cases()` and `start_test()` methods.

A `skip_combinations()` method returns a hash that maps file names (where combinations are defined) to a list of combinations that should be skipped. As a special case, it can disable a complete file by using a string instead of a hash. For example

```
sub skip_combinations {(
    'combinations' => [ 'mix', 'rpl' ],
    'inc/many.combinations' => [ 'a', 'bb', 'c' ],
    'windows.inc' => "Not on windows",
)}
```

The last line will cause all tests of this suite that include `windows.inc` to be skipped with the reason being “Not on windows”.

An `is_default()` method returns 1 if this particular suite should be run by default, when the `mariadb-test-run.pl` script is run without explicitly specified test suites or test cases.

`*.sh` files

For every test file `sometest.test` mtr looks for `sometest-master.sh` and `sometest-slave.sh`. If either of these files is found, it is run before the test itself.

`*.require` files

These files are obsolete. Do not use them anymore. If you need to skip a test use the `skip` command instead.

`*.rdiff` files

These files also define what the test result should be. But unlike `*.result` files, they contain a patch that should be applied to one result file to create a new result file. This is very useful when a result of some test in one combination differs slightly from the result of the same test, but in another combination. Or when a result of a test in an overlay differs from the test result in the overlaid suite.

It is quite difficult to edit `.rdiff` files to update them after the test file has changed. But luckily, it is never needed. When a test fails, mtr creates a `.reject` file. Having it, one can create `.rdiff` file as easy as (for example)

```
diff -u main/foo.result main/foo.reject > main/foo,comb.rdiff
or
diff -u main/foo.result main/foo,comb.reject > main/foo,comb.rdiff
```

Some example:

```
diff -u main/innodb_ext_key.result main/innodb_ext_key,off.reject > main/innodb_ext_key,off.rdiff

diff -u suite/sys_vars/r/sysvars_server_notembedded.result
suite/sys_vars/r/sysvars_server_notembedded,32bit.reject >
suite/sys_vars/r/sysvars_server_notembedded,32bit.rdiff
```

Note: This will also add a timestamp in the .rdiff file, so if you are submitting a patch you could remove it manually. If the same .rdiff file is used for multiple combinations, then it would be good to omit in the header that would identify the combination, to allow git to pack the repository better. Example:

```
--- testname.result
+++ testname.reject
```

Because a combination can be part of the `.result` or `.rdiff` file name, mtr has to look in many different places for a test result. For example, consider a test `foo.test` in the combination pair `aa,bb`, that is run in the overlay *rty* of the suite *qwe*, in other words, for the test that mtr prints as

```
qwe-rty.foo 'aa,bb'                    [ pass ]
```

For this test a result can be in

- either `.rdiff` or `.result` file
- either in the overlay "`rty/`" or in the overlaid suite "`qwe/`"
- with or without combinations in the file name ("`,a`", "`,b`", "`,a,b`", or nothing)

which means any of the following 15 file names can be used:

1. `rty/r/foo,aa,bb.result`
2. `rty/r/foo,aa,bb.rdiff`
3. `qwe/r/foo,aa,bb.result`
4. `qwe/r/foo,aa,bb.rdiff`

5. `rty/r/foo,aa.result`
6. `rty/r/foo,aa.rdiff`
7. `qwe/r/foo,aa.result`
8. `qwe/r/foo,aa.rdiff`
9. `rty/r/foo,bb.result`
10. `rty/r/foo,bb.rdiff`
11. `qwe/r/foo,bb.result`
12. `qwe/r/foo,bb.rdiff`
13. `rty/r/foo.result`
14. `rty/r/foo.rdiff`
15. `qwe/r/foo.result`

They are listed, precisely, in the order of preference, and mtr will walk that list from top to bottom and the first file that is found is used.

If this found file is a `.rdiff`, mtr continues walking down the list until the first `.result` file is found. A `.rdiff` is applied to that `.result`.

`valgrind.supp` file

This file defines valgrind suppressions, and it is used when mtr is started with a `--valgrind` option.

mariadb-test-run.pl Options

Syntax

```
./mariadb-test-run.pl [ OPTIONS ] [ TESTCASE ]
```

Where the test case can be specified as: `testcase[.test]` Runs the test case named 'testcase' from all suites.

```
path-to-testcase
[suite.]testcase[,combination]
```

Examples

`aliasmain.alias` 'main' is the name of the suite for the 't' directory.

```
rpl.rpl_invoked_features,mix,xtradb_plugin
suite/rpl/t/rpl.rpl_invoked_features
```

Options

Options to Control What Engine/Variation to Run

Option	Description
–embedded-server	Use the embedded server, i.e., no mysqld daemons.

Option	Description
–ps-protocol	Use the binary protocol between client and server.
–cursor-protocol	Use the cursor protocol between client and server (implies –ps-protocol).
–view-protocol	Create a view to execute all non- updating queries.
–sp-protocol	Create a stored procedure to execute all queries.
–compress	Use the compressed protocol between client and server if both support it.
–ssl	If mariadb-test-run.pl is started with the –ssl option, it sets up a secure connection for all test cases. In this case, if mysqld does not support TLS, mariadb-test-run.pl exits with an error message: Couldn't find support for SSL.
–skip-ssl	Don't start the server with support for TLS connections.
–vs-config	Visual Studio configuration used to create executables (default: MTR_VS_CONFIG environment variable).
–parallel=num	How many parallel tests should be run. Default is 1, use –parallel=auto for auto-setting of num.
–defaults-file=	Use a fixed config template for all tests.
–defaults_extra_file=	Extra config template to add to all generated configs.
–combination=	Extra options to pass to mysqld. The value should consist of one or more comma-separated mysqld options. This option is similar to –mysqld but should be given two or more times. mariadb-test-run.pl executes multiple test runs, using the options for each instance of –combination in successive runs. If –combination is given only once, it has no effect. For test runs specific to a given test suite, an alternative to the use of –combination is to create a combinations file in the suite directory. The file should contain a section of options for each test run.
–dry-run	Don't run any tests; print the list of tests that were selected for execution.

Options to Control Directories to Use

Option	Description
–tmpdir=DIR	The directory where temporary files are stored (default: ./var/tmp). The environment variable MYSQL_TMP_DIR is set to the path for this directory, whether it has the default value or has been set explicitly. This may be referred to in tests.
–vardir=DIR	The directory where files generated from the test run is stored (default: ./var). Specifying a ramdisk or tmpfs will speed up tests. The environment variable MYSQLTEST_VARDIR is set to the path for this directory, whether it has the default value or has been set explicitly. This may be referred to in tests.

Option	Description
–mem	Run testsuite in “memory” using tmpfs or ramdisk. This can decrease test times significantly, in particular if you would otherwise be running over a remote file system. Attempts to find a suitable location using a built-in list of standard locations for tmpfs (/dev/shm). The option can also be set using the environment variable MTR_MEM=[DIR]. If DIR is given, it is added to the beginning of the list of locations to search, so it takes precedence over any built-in locations. Once you have run tests with –mem within a mariadb-testdirectory, a soflink var will have been set up to the temporary directory, and this is reused the next time, until the soflink is deleted. Thus, you do not have to repeat the –mem option next time.
–client-bindir=PATH	Path to the directory where client binaries are located.
–client-libdir=PATH	Path to the directory where client libraries are located.

Options to Control What Test Suites or Cases to Run

Option	Description
–force	Normally, mariadb-test-run.pl exits if a test case fails. –force causes execution to continue regardless of test case failure.
–with-ndbcluster-only	Run only tests that include “ndb” in the filename.
–skip-ndb[cluster]	Skip all tests that need a cluster. Default.
–do-test=PREFIX or REGEX	Run test cases with names prefixed with PREFIX or that fulfil the REGEX. For example, –do-test=testa matches tests that begin with testa, –do-test=main.testa matches tests in the main test suite that begin with testa, and –do-test=main.*testa matches test names that contain main followed by testa with anything in between. In the latter case, the pattern match is not anchored to the beginning of the test name, so it also matches names such as xmainytestz.
–skip-test=PREFIX or REGEX	Skip test cases with names prefixed with PREFIX or that fulfil the REGEX. See -do-test for examples.
–start-from=PREFIX	Sorts the list of names of the test cases to be run, and then starts with the test prefixed with PREFIX, where the prefix may be suite.testname or just testname.
–suite[s]=NAME1,...,NAMEN	Comma separated list of suite names to run. The default, as of MariaDB 10.4.5, is:“main-, archive-, binlog-, binlog_encryption-, csv-, compat/oracle-, encryption-, federated-, funcs_1-, funcs_2-, gcol-, handler-, heap-, innodb-, innodb_fts-, innodb_gis-, innodb_zip-, json-, maria-, mariadb-backup-, multi_source-, optimizer_unfixed_bugs-, parts-, perfschema-, plugins-, roles-, rpl-, sys_vars-, sql_sequence-, unit-, vcol-, versioning-,period-”.
–skip-rpl	Skip the replication test cases.
–big-test	Allow tests marked as “big” to run. Tests can be thus marked by including the line –source include/big_test.inc, and they will only be run if this option is given, or if the environment variable BIG_TEST is set to 1. Repeat this option twice to run only “big” tests. This is typically used for tests that take a very long time to run, or that use many resources, so that they are not suitable for running as part of a normal test suite run.
–staging-run	Run a limited number of tests (no slow tests). Used for running staging trees with valgrind.
–enable-disabled	Ignore any disabled.def file, and also run tests marked as disabled. Success or failure of those tests is reported the same way as other tests.

Option	Description
–print-testcases	Don't run the tests, but print details about all the selected tests, in the order they would be run.
–skip-test-list=FILE	Skip the tests listed in FILE. Each line in the file is an entry and should be formatted as: <TESTNAME>:<COMMENT>.

Options That Specify Ports

Option	Description
–[mtr-]port-base=num	Base for port numbers. Ports from this number to number+9 are reserved. Should be divisible by 10; if not it is rounded down. May be set with the environment variable MTR_PORT_BASE. If this value is set and is not "auto", it overrides build-thread.
–[mtr-]build-thread=num	Specify a unique number to calculate port number(s) from. Can be set in the environment variable MTR_BUILD_THREAD. Set MTR_BUILD_THREAD="auto" to automatically acquire a build thread id that is unique to the current host. The more logical –port-base is supported as an alternative.

Options For Test Case Authoring

Option	Description
–record TESTNAME	(Re)generate the result file for TESTNAME.
–check-testcases	Check testcases for side-effects. This is done by checking the system state before and after each test case; if there is any difference, a warning to that effect is written, but the test case will not be marked as failed because of it. This check is enabled by default. Use –nocheck-testcases to disable.
mark-progress	Log line number and elapsed time to <testname>.progress

Options That Pass On Options

Option	Description
–mysqld=ARGS	Specify additional arguments to "mysqld"
–mysqltest=ARGS	Specify additional arguments to "mariadb-test". Use additional –mysqld-env options to set more than one variable.

Options to Run Test On Running Server

Option	Description
extern option=value	Use an already running server. The option/value pair is what is needed by the mariadb client to connect to the server. Each –extern option can only take one option/value pair as an argument, so you need to repeat –extern for each pair needed. Example: ./mariadb-test-run.pl –extern socket=var/tmp/mysqld.1.sock alias. Note: If a test case has an .opt file that requires the server to be restarted with specific options, the file will not be used. The test case likely will fail as a result.

Options For Debugging the Product

In `mariadb-test-run.pl`, there is a concept of a "debugger". A "debugger" is a tool that `mariadb-test-run.pl` will execute instead of `mariadbd`. This tool will then start `mariadbd` and can control its execution as it wants. The following "debuggers" are supported:

name	Description
gdb	GNU debugger
ddd	GUI frontend for gdb

name	Description
dbx	Dbx_(debugger)
devenv	Visual Studio debugger
windbg	WinDbg
lldb	Debugger from LLVM project
valgrind	Detects memory management problems and more
strace	syscall tracer
rr	“record and replay” — record the program execution and then replay it forward, backward, or in any other direction

Every “debugger” from the list above supports the following set of options (replace XXX below with a debugger name)

Option	Description
–XXX	Start mariadbd process under a debugger
–client-XXX	Start mariadb-test process under a debugger
–boot-XXX	Before running tests, mariadb-test-run executes mariadbd to bootstrap, prepare the datadir. This option causes this bootstrapping mariadbd process to be run under a debugger.
–manual-XXX	Don’t start anything; instead, print the command that the user needs to run to start mariadbd under a debugger. Then wait.

Every option from the above accepts an optional argument. It can be used to specify additional command-line options to pass to the tool. Or additional commands that the tool will run on startup. Or both. Commands are separated from each other and from options with a semicolon. For example:

```
./mtr 1st --strace
./mtr 1st --client-rr=--chaos
./mtr 1st --manual-gdb='b mysql_parse;r'
./mtr 1st --boot-gdb='--quiet --tui;b mysql_parse;r'
```

Misc Debugging Related Options

Option	Description
–debug	Dump trace output for all servers and client programs.
–debug-common	Same as –debug, but sets the ‘d’ debug flags to “query,info,error,enter,exit”
–debug-server	Use the debug version of the server, but without turning on tracing.
–max-save-core	Limit the number of core files saved (to avoid filling up disks for a heavily crashing server). Defaults to 5, set to 0 for no limit. Set its default with MTR_MAX_SAVE_CORE.
–max-save-datadir	Limit the number of datadir saved (to avoid filling up disks for a heavily crashing server). Defaults to 20, set to 0 for no limit. Set its default with MTR_MAX_SAVE_DATDIR.
–max-test-fail	Limit the number of test failures before aborting the current test run. Defaults to 10, set to 0 for no limit. Set its default with MTR_MAX_TEST_FAIL.

Misc Options

Option	Description
–user=USER	User for connecting to mysqld (default: root)

Option	Description
–comment=STR	Write STR to the output within lines filled with #, as a form of banner.
–timer	Show test case execution time. Use no-timer to disable.
–verbose	More verbose output (use multiple times for even more)
–verbose-restart	Write when and why servers are restarted between test cases.
–start	Only initialize and start the servers, using the startup settings for the first specified test case. Example: ./mariadb-test-run.pl –start alias & start-dirty. Only start the servers (without initialization) for the first specified test case
–start-and-exit	Same as –start, but mariadb-test-run terminates and leaves just the server running.
–start-dirty	This is similar to –start, but will skip the database initialization phase and assume that database files are already available. Usually, this means you must have run another test first.
–user-args	In combination with start* and no test name, drops arguments to mysqld except those specified with –mysqld (if any).
–wait-all	If –start or –start-dirty option is used, wait for all servers to exit before finishing the process. Otherwise, it will terminate if one (of several) servers is restarted.
–fast	Do not perform a controlled shutdown when servers need to be restarted or at the end of the test run. This is equivalent to using –shutdown-timeout=0.
–force-restart	Always restart servers between tests.
–parallel=N	Run tests in N parallel threads (default 1). Use parallel=auto for auto-setting of N.
–repeat=N	Run each test N number of times.
–retry=N	If a test fails, it is retried up to a maximum of N runs (default 1). Retries are also limited by the maximum number of failures before stopping, set with the –retry-failure option. This option has no effect unless –force is also used; without it, test execution will terminate after the first failure. The –retry and –retry-failure options do not affect how many times a test repeated with –repeat may fail in total, as each repetition is considered a new test case, which may in turn be retried if it fails.
–retry-failure=N	When using the –retry option to retry failed tests, stop when N failures have occurred (default 2). Setting it to 0 or 1 effectively turns off retries.
–reorder	Reorder tests to get fewer server restarts. This is the default behavior. There is no guarantee that a particular set of tests will always end up in the same order. Use -no-reorder to disable.
–help	Display help text.
–testcase-timeout=MINUTES	Max test case run time in minutes (default 15).
–suite-timeout=MINUTES	Max test suite run time in minutes (default 360).
–shutdown-timeout=SECONDS	Max number of seconds to wait for server shutdown before killing servers (default 10).
–warnings	Scan the log files for warnings and report any suspicious ones; if any are found, the test is marked as failed. Use –nowarnings to turn off.

Option	Description
–stop-file=file	If this file is detected, mariadb-test will not start new tests until the file is removed (also the MTR_STOP_FILE environment variable).
–stop-keep-alive=sec	Works with –stop-file, print messages every second when mariadb-test is waiting to remove the file (for buildbot) (also MTR_STOP_KEEP_ALIVE environment variable).
–sleep=SECONDS	Passed to mariadb-test; it is used as a fixed sleep time.
–debug-sync-timeout=NUM	Set default timeout for WAIT_FOR debug sync actions. Disable facility with NUM=0.
–gcov	Collect coverage information after the test. The result is a dgcov file per source and header file, and a last_changes.dgcov file in the vardir with the coverage for the uncommitted changes, if any (or the last commit).
–gprof	Collect profiling information using the gprof profiling tool.
–experimental=	Specify a file that contains a list of test cases that should be displayed with the [exp-fail] code rather than [fail] if they fail. For an example of a file that might be specified via this option, see mariadb-test/collections/default.experimental.
–report-features	First, run a “test” that reports MariaDB features, displaying the output of SHOW ENGINES and SHOW VARIABLES. This can be used to verify that binaries are built with all required features.
–timestamp	Print the timestamp before each test report line, showing when the test ended.
–timediff	Used with –timestamp, also print the time passed since the previous test started.
–max-connections=N	Maximum number of simultaneous server connections that may be used per test. Default is 128. Minimum is 8, maximum is 5120. Corresponds to the same option for mariadb-test.
–default-myisam	Set default storage engine to MyISAM for non-innodb tests. This is needed after switching the default storage engine to InnoDB.
–report-times	Report how much time has been spent on different phases of test execution.
–stress=ARGS	Run stress test, providing options to mysql-stress-test.pl. Options are separated by a comma.
xml-report=	Output jUnit xml file of the results. From MariaDB 10.1.45, MariaDB 10.2.32, MariaDB 10.3.23, MariaDB 10.4.13, MariaDB 10.5.3
tail-lines=N	Number of lines of the result to include in a failure report. From MariaDB 10.3.4.

New Features for mysqltest in MariaDB

> **Note:**
>
> Note that not all MariaDB-enhancements are listed on this page. See mariadb-test and mariadb-test-embedded for a full set of options.

Startup Option –connect-timeout

```
--connect-timeout=N
```

This can be used to set the MYSQL_OPT_CONNECT_TIMEOUT parameter of mysql_options, to change the number of seconds before an unsuccessful connection attempt times out.

Test Commands for Handling Warnings During Prepare Statements

- `enable_prepare_warnings;`
- `disable_prepare_warnings;`

Normally, when running with the prepared statement protocol with warnings enabled and executing a statement that returns a result set (like SELECT), warnings that occur during the execute phase are shown, but warnings that occur during the prepare phase are ''not'' shown. The reason for this is that some warnings are returned both during prepare and execute; if both copies of warnings were shown, then test cases would show different number of warnings between prepared statement execution and normal execution (where there is no prepare phase).

The `enable_prepare_warnings` command changes this so that warnings from both the prepare and execute phase are shown, regardless of whether the statement produces a result set in the execute phase.
The `disable_prepare_warnings` command reverts to the default behaviour.

These commands only have effect when running with the prepared statement protocol (–ps-protocol) *and* with warnings enabled (enable_warnings). Furthermore, they only have effects for statements that return a result set (as for statements without result sets, warnings from are always shown when warnings are enabled).

The `replace_regex` command supports paired delimiters (like in perl, etc). If the first non-space character in the `replace_regex` argument is one of `(`, `[`, `{`, `<`, then the pattern should end with `)`, `]`, `}`, `>` accordingly. The replacement string can use its own pair of delimiters, not necessarily the same as the pattern. If the first non-space character in the `replace_regex` argument is not one of the above, then it should also separate the pattern and the replacement string and it should end the replacement string. Backslash can be used to escape the current terminating character as usual. The examples below demonstrate valid usage of `replace_regex`:

```
--replace_regex (/some/path)</another/path>
--replace_regex !/foo/bar!foobar!
--replace_regex {pat\}tern}/replace\/ment/i
```

Dumping “exec” output on errors only

Sometimes it is only interesting to see the output of a utility to stdout/stderr, if utility failed. In case of success, the output might be unpredictable, and contain timestamps, startup messages etc. mariadb-backup can be a good example of such utility.

mysqltest in MariaDB can helps in this situation. In the example below, the output of $XTRABACKUP is suppressed, however if `exec` fails, stdout and stderr both is dumped , to aid diagnostics:

```
--disable_result_log
exec $XTRABACKUP  --param1 --param2  # Note, do not use output redirection here
--enable_result_log
```

Pausing mariadb-test-run.pl

Sometimes you need to work when your computer is busy running mariadb-test-run.pl. The mariadb-test-run.pl script allows you to stop it temporarily so you can use your computer and then restart the tests when you’re ready.

There are two ways to enable this:

1. Command-line: The `--stop-file` and `--stop-keep-alive` options.
2. Environment Variables: If you are calling mariadb-test-run.pl indirectly (i.e from a script or program such as buildbot) you can set `MTR_STOP_FILE` and `MTR_STOP_KEEP_ALIVE`.

Keep Alive

If you plan on using this feature with other programs, such as buildbot, you should set the `MTR_STOP_KEEP_ALIVE` environment variable or the `--stop-keep-alive` command line option with a value in seconds. This will make the script print messages to whatever program is calling mariadb-test-run.pl at the interval you set to prevent timeouts.

If you are calling mariadb-test-run.pl directly, you do not need to specify a timeout.

The mariadb-test-run Stop File

The stop file is a temporary file that you create on your system when you want to pause the execution of mariadb-test-run. When enabled via the command line or environment variable options, mariadb-test-run will periodically check for the existence of the file and if it exists it will stop until the file is no longer present.

Examples

Command-line:

```
mariadb-test-run.pl --stop-file="/path/to/stop/file" --stop-keep-alive=120
```

Environment Variables:

```
export MTR_STOP_FILE="/path/to/stop/file"
export MTR_STOP_KEEP_ALIVE=120
mariadb-test-run.pl
```

The Debug Sync Facility

The Debug Sync Facility allows placement of synchronization points in the server code by using the DEBUG_SYNC macro:

```
open_tables(...)

DEBUG_SYNC(thd, "after_open_tables");

lock_tables(...)
```

When activated, a sync point can

- Emit a signal and/or
- Wait for a signal

Nomenclature	Description
signal	A value of a global variable that persists until overwritten by a new signal. The global variable can also be seen as a “signal post” or “flag mast”. Then the signal is what is attached to the “signal post” or “flag mast”.
emit a signal	Assign the value (the signal) to the global variable (“set a flag”) and broadcast a global condition to wake those waiting for a signal.
wait for a signal	Loop over waiting for the global condition until the global value matches the wait-for signal.

By default, all sync points are inactive. They do nothing (except to burn a couple of CPU cycles for checking if they are active).

A sync point becomes active when an action is requested for it.
To do so, put a line like this in the test case file:

```
SET DEBUG_SYNC= 'after_open_tables SIGNAL opened WAIT_FOR flushed';
```

This activates the sync point `'after_open_tables'`. It requests it to emit the signal `'opened'` and wait for another thread to emit the signal `'flushed'` when the thread's execution runs through the sync point.

For every sync point there can be one action per thread only. Every thread can request multiple actions, but only one per sync point. In other words, a thread can activate multiple sync points.

Here is an example how to activate and use the sync points:

```
--connection conn1
SET DEBUG_SYNC= 'after_open_tables SIGNAL opened WAIT_FOR flushed';
send INSERT INTO t1 VALUES(1);
    --connection conn2
    SET DEBUG_SYNC= 'now WAIT_FOR opened';
    SET DEBUG_SYNC= 'after_abort_locks SIGNAL flushed';
    FLUSH TABLE t1;
```

When `conn1` runs through the `INSERT` statement, it hits the sync point `'after_open_tables'`. It notices that it is active and executes its action. It emits the signal `'opened'` and waits for another thread to emit the signal `'flushed'`.

`conn2` waits immediately at the special sync point `'now'` for another thread to emit the `'opened'` signal.

A signal remains in effect until it is overwritten. If `conn1` signals `'opened'` before `conn2` reaches `'now'`, `conn2` will still find the `'opened'` signal. It does not wait in this case.

When `conn2` reaches `'after_abort_locks'`, it signals `'flushed'`, which lets `conn1` awake.

Normally the activation of a sync point is cleared when it has been executed. Sometimes it is necessary to keep the sync point active for another execution. You can add an execute count to the action:

```
SET DEBUG_SYNC= 'name SIGNAL sig EXECUTE 3';
```

This sets the signal point's activation counter to 3. Each execution decrements the counter. After the third execution the sync point becomes inactive.

One of the primary goals of this facility is to eliminate sleeps from the test suite. In most cases it should be possible to rewrite test cases so that they do not need to sleep. (But this facility cannot synchronize multiple processes.) However, to support test development, and as a last resort, sync point waiting times out. There is a default timeout, but it can be overridden:

```
SET DEBUG_SYNC= 'name WAIT_FOR sig TIMEOUT 10 EXECUTE 2';
```

`TIMEOUT 0` is special: If the signal is not present, the wait times out immediately.

When a wait timed out (even on `TIMEOUT 0`), a warning is generated so that it shows up in the test result.

You can throw an error message and kill the query when a synchronization point is hit a certain number of times:

```
SET DEBUG_SYNC= 'name HIT_LIMIT 3';
```

Or combine it with signal and/or wait:

```
SET DEBUG_SYNC= 'name SIGNAL sig EXECUTE 2 HIT_LIMIT 3';
```

Here the first two hits emit the signal, the third hit returns the error message and kills the query.

For cases where you are not sure that an action is taken and thus cleared in any case, you can force to clear (deactivate) a sync point:

```
SET DEBUG_SYNC= 'name CLEAR';
```

If you want to clear all actions and clear the global signal, use:

```
SET DEBUG_SYNC= 'RESET';
```

This is the only way to reset the global signal to an empty string.

For testing of the facility itself you can execute a sync point just as if it had been hit:

```
SET DEBUG_SYNC= 'name TEST';
```

Formal Syntax

The string to "assign" to the DEBUG_SYNC variable can contain:

```
RESET |
<sync point name> TEST |
<sync point name> CLEAR |
<sync point name> {{SIGNAL <signal name> |
                   WAIT_FOR <signal name> [TIMEOUT <seconds>]}
                   [EXECUTE <count>] &| HIT_LIMIT <count>}
```

Here '&|' means 'and/or'. This means that one of the sections separated by '&|' must be present or both of them.

Activation/Deactivation

With a MariaDB for debug build, it can be enabled by a mysqld command line option:

```
--debug-sync-timeout[=default_wait_timeout_value_in_seconds]
```

`'default_wait_timeout_value_in_seconds'` is the default timeout for the `WAIT_FOR` action. If set to zero, the facility stays disabled.

The facility is enabled by default in the test suite, but can be disabled with:

```
mariadb-test-run.pl ... --debug-sync-timeout=0 ...
```

Likewise the default wait timeout can be set:

```
mariadb-test-run.pl ... --debug-sync-timeout=10 ...
```

The command line option influences the readable value of the debug_sync system variable.

- If the facility is not compiled in, the system variable does not exist.
- If `--debug-sync-timeout=0` the value of the variable reads as `"OFF"`.
- Otherwise the value reads as `"ON - current signal: "` followed by the current signal string, which can be empty.

The readable variable value is the same, regardless if read as a global or session value.

Setting the debug_sync system variable requires the `'SUPER'` privilege. You can never read back the string that you assigned to the variable, unless you assign the value that the variable already has. But that would give a parse error. A syntactically correct string is parsed into a debug sync action and stored apart from the variable value.

Implementation

Pseudo code for a sync point:

```
#define DEBUG_SYNC(thd, sync_point_name)
        if (unlikely(opt_debug_sync_timeout))
          debug_sync(thd, STRING_WITH_LEN(sync_point_name))
```

The sync point performs a binary search in a sorted array of actions for this thread.

The `SET DEBUG_SYNC` statement adds a requested action to the array or overwrites an existing action for the same sync point. When it adds a new action, the array is sorted again.

A typical synchronization pattern

There are quite a few places in MariaDB and MySQL where we use a synchronization pattern like this:

```
mysql_mutex_lock(&mutex);
thd->enter_cond(&condition_variable, &mutex, new_message);
#if defined(ENABLE_DEBUG_SYNC)
if (!thd->killed && !end_of_wait_condition)
   DEBUG_SYNC(thd, "sync_point_name");
#endif
while (!thd->killed && !end_of_wait_condition)
  mysql_cond_wait(&condition_variable, &mutex);
thd->exit_cond(old_message);
```

Here are some explanations:

`thd->enter_cond()` is used to register the condition variable and the mutex in `thd->mysys_var`. This is done to allow the thread to be interrupted (killed) from its sleep. Another thread can find the condition variable to signal and mutex to use for synchronization in this thread's `THD::mysys_var`.

`thd->enter_cond()` requires the mutex to be acquired in advance.

`thd->exit_cond()` unregisters the condition variable and mutex and releases the mutex.

If you want to have a Debug Sync point with the wait, please place it behind `enter_cond()`. Only then you can safely decide, if the wait is taken. Also you will have `THD::proc_info` correct when the sync point emits a signal. `DEBUG_SYNC` sets its own proc_info, but restores the previous one before releasing its internal mutex. As soon as another thread sees the signal, it does also see the proc_info from before entering the sync point. In this case it is "new_message", which is associated with the wait that is to be synchronized.

In the example above, the wait condition is repeated before the sync point. This is done to skip the sync point, if no wait takes place.
The sync point is before the loop (not inside the loop) to have it hit once only. It is possible that the condition variable is signaled multiple times without the wait condition to be true.

A bit off-topic: At some places, the loop is taken around the whole synchronization pattern:

```
while (!thd->killed && !end_of_wait_condition)
{
  mysql_mutex_lock(&mutex);
  thd->enter_cond(&condition_variable, &mutex, new_message);
  if (!thd->killed [&& !end_of_wait_condition])
  {
    [DEBUG_SYNC(thd, "sync_point_name");]
    mysql_cond_wait(&condition_variable, &mutex);
  }
  thd->exit_cond(old_message);
}
```

Note that it is important to repeat the test for thd->killed after `enter_cond()`. Otherwise the killing thread may kill this thread after it tested `thd->killed` in the loop condition and before it registered the condition variable and mutex in `enter_cond()`. In this case, the killing thread does not know that this thread is going to wait on a condition variable. It would just set `THD::killed`. But if we would not test it again, we would go asleep though we are killed. If the killing thread would kill us when we are after the second test, but still before sleeping, we hold the mutex, which is registered in mysys_var.
The killing thread would try to acquire the mutex before signaling the condition variable. Since the mutex is only released implicitly in `mysql_cond_wait()`, the signaling happens at the right place. We have a safe synchronization.

Co-work with the DBUG facility

When running the MariaDB test suite with the `--debug-dbug` command line option, the Debug Sync Facility writes trace messages to the DBUG trace. The following shell commands proved very useful in extracting relevant information:

```
egrep 'query:|debug_sync_exec:' mysql-test/var/log/mysqld.1.trace
```

It shows all executed SQL statements and all actions executed by synchronization points.

Sometimes it is also useful to see, which synchronization points have been run through (hit) with or without executing actions. Then add `"|debug_sync_point:"` to the egrep pattern.

Synchronizing DEBUG_SYNC Actions

Tests may need additional synchronization mechanisms between `DEBUG_SYNC` actions, because certain combinations of actions can result in lost signals. More specifically, once a `SIGNAL` action is issued, it is stored in a global variable for any waiting threads to determine if they are depending on that signal for continuing. However, if a subsequent action overwrites that variable before a waiting thread is able to check against it, the original signal is lost. Examples of actions which would change the variable state are another `SIGNAL` or a `RESET`. Therefore, before issuing these commands, the test writer should verify the previous signal has been acknowledged. The following code snippets show an example of a problematic pattern and a potential solution.

```
SET DEBUG_SYNC='now SIGNAL sig';
SET DEBUG_SYNC='RESET'; # Problematic because sig can be cleared before a waiting thread can acknowledge
it
```

```
SET DEBUG_SYNC='now SIGNAL sig';

# Don't issue the RESET until we have proven the waiting thread has received the signal
let $wait_condition= select count(*)=0 from information_schema.processlist where state like "debug sync
point%";
source include/wait_condition.inc;

SET DEBUG_SYNC='RESET'; # Now this is safe
```

Memory and Disk Use With myisamchk

myisamchk's performance can be dramatically enhanced for larger tables by making sure that its memory-related variables are set to an optimum level.

By default, myisamchk will use very little memory (about 3MB is allocated), but can temporarily use a lot of disk space. If disk space is a limitation when repairing, the *–safe-recover* option should be used instead of *–recover*. However, if TMPDIR points to a memory file system, an out of memory error can easily be caused, as myisamchk places temporary files in TMPDIR. The *–tmpdir=path* option should be used in this case to specify a directory on disk.

myisamchk has the following requirements for disk space:

- When repairing, space for twice the size of the data file, available in the same directory as the original file. This is for the original file as well as a copy. This space is not required if the –quick option is used, in which case only the index file is re-created.
- Disk space in the temporary directory (TMPDIR or the tmpdir=path option) is needed for sorting if the –recover or –sort-recover options are used when not using –safe-recover). The space required is approximately (largest_key + row_pointer_length) * number_of_rows * 2. To get information about the length of the keys as well as the row pointer length, use myisamchk -dv table_name.
- Space for a new index file to replace the existing one. The old index is first truncated, so unless the old index file is not present or is smaller for some reason, no significant extra space is needed.

There are a number of system variables that are useful to adjust when running myisamchk. They will increase memory usage, and since some are per-session variables, you don't want to increase the general value, but you can either pass an increased value to myisamchk as a command line option, or with a [myisamchk] section in your my.cnf file.

- sort_buffer_size. By default this is 4M, but it's very useful to increase to make myisamchk sorting much faster. Since the server won't be running when you run myisamchk, you can increase substantially. 16M is usually a minimum, but values such as 256M are not uncommon if memory is available.
- key_buffer_size (which particularly helps with the –extend-check and –safe-recover options.
- read_buffer_size
- write_buffer_size

For example, if you have more than 512MB available to allocate to the process, the following settings could be used:

```
myisamchk
  --myisam_sort_buffer_size=256M
  --key_buffer_size=512M
  --read_buffer_size=64M
  --write_buffer_size=64M
...
```

MyISAM Database Management using GUI Client

Navigating the complexities of database management requires the right tools and know-how, especially when dealing with specialized storage engines like MyISAM in MySQL and MariaDB environments. This comprehensive guide demystifies the role and functionality of MyISAM clients, offering you a deep dive into their essential features and operations. From initiating CRUD operations to optimizing table performance, we cover it all. We also spotlight dbForge Studio for MySQL, a feature-rich IDE that simplifies your interactions with MyISAM tables and databases. Whether you're a seasoned DBA or a developer looking to sharpen your database skills, this article serves as your go-to resource for understanding MyISAM clients and maximizing their capabilities.

What is a MyISAM client?

A MyISAM client refers to a specialized application or module designed to interact with the MyISAM database storage engine. Its primary function is to facilitate essential database operations such as creating, reading, updating, and deleting data (commonly referred to as CRUD operations) through specific protocols, APIs, or query languages.

In the context of MyISAM, it's important to note that we are essentially referring to a MySQL/MariaDB client, as the MyISAM storage engine is an integral part of these database management systems. A MyISAM client plays a pivotal role in initiating database management processes, sending queries to databases, and handling subsequent responses.

In simpler terms, any MyISAM client serves as the interface that allows users to interact with MySQL/MariaDB. There is a wide range of available solutions catering to different needs, including lightweight command line utilities like **myisamchk**, versatile options like the MySQL Command-Line Client, and feature-rich IDEs based on graphical user interfaces, such as MySQL Workbench or dbForge Studio for MySQL.

The choice of the right client largely depends on user preferences, the specific work environment, and the tasks they need to accomplish.

How it works: a MyISAM client in action

To better understand the functionality of a MyISAM client, let's delve into a practical scenario where a user needs to compose and execute a query against the database and subsequently retrieve the results. Whether you opt for a command line or GUI client, the process unfolds as follows:

Step 1: Connection Setup

The client initiates a connection to a MySQL/MariaDB server using the necessary library or connector. During this setup, it provides authentication credentials and specifies the database to be accessed.

Step 2: Query Submission

The client sends SQL queries to the MySQL/MariaDB server, utilizing the appropriate database engine—in our case, MyISAM.

Note: Modern GUI-based database clients, like dbForge Studio for MySQL and MariaDB, enhance query writing by offering essential features such as code auto-completion, formatting, debugging, code snippet libraries, and visual query builders for constructing intricate queries through diagrams.

Step 3: Query Execution

The database system takes charge of parsing and executing the SQL query. When the query involves a table managed by the MyISAM storage engine, MyISAM handles the data and its storage particulars.

Step 4: Result Retrieval

Upon completing query processing, the results are transmitted back to the client. The client then handles these results as needed—whether it's displaying them to the user or employing them for further operations.

Step 5: Connection Closure

Once the interaction is finished, the client responsibly closes the connection.

Throughout this process, it's essential to note that the client does not directly engage with MyISAM or any other storage engines. Instead, it interacts with the MySQL/MariaDB server, which, in turn, utilizes MyISAM to manage data at its level.

dbForge Studio for MySQL and MariaDB as the MyISAM client

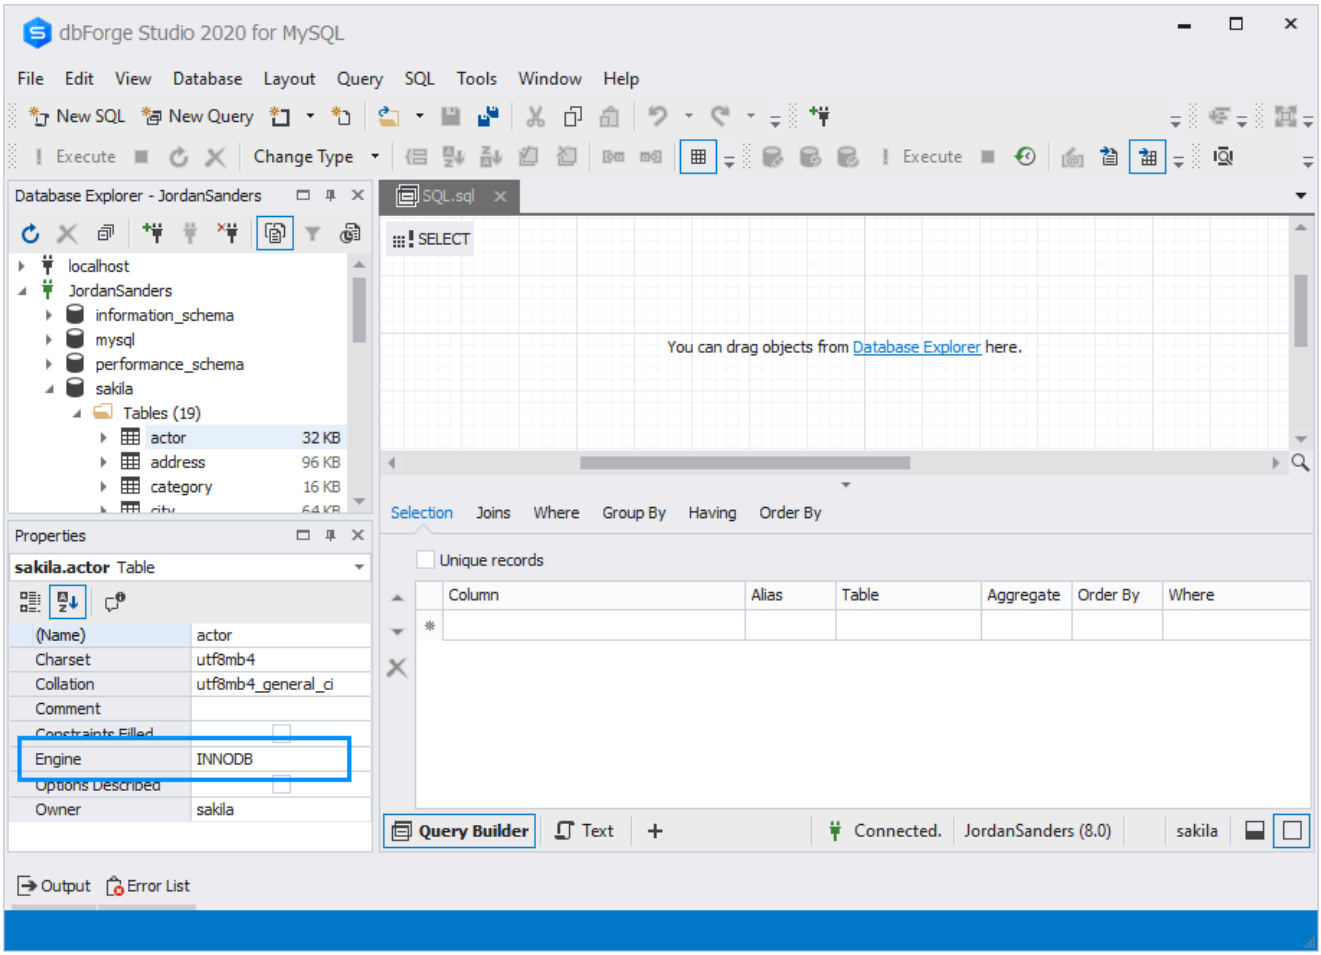
dbForge Studio for MySQL that is also a viable MariaDB tool offers full support for all MySQL storage engines, including MyISAM, and a user-friendly graphical interface that simplifies interactions with MyISAM tables. The functionality of the Studio makes it the common choice for professionals who prefer GUI tools over command line utilities.

It includes options available in the **myisamchk** utility and provides many more features to cover all database-related tasks on MySQL and MariaDB, no matter which storage engine those databases use.

Speaking of MyISAM tables, it is worth mentioning some basic operations.

Check what storage engine is used in the database

In dbForge Studio for MySQL, you can check the storage engine of the current database in a couple of clicks. Select the database in Database Explorer, right-click the necessary table, and select **Properties** from the shortcut menu. The output will present the information of the database engine among other data.



Check storage engine

Convert a table from InnoDB to MyISAM (and vice versa)

If you need to switch between database engines for some tables, you can use the standard ALTER TABLE command. dbForge Studio for MySQL allows executing SQL queries directly against the database.

To convert an InnoDB table to MyISAM, use the following command:

ALTER TABLE database_name.table_name ENGINE=MyISAM;

Img 1 – InnoDB, img 2 – MyISAM

The same ALTER TABLE command serves in the opposite situation where you want to convert MyISAM tables to InnoDB. You will need to specify ENGINE=InnoDB in that case.

MyISAM does not support foreign key constraints that are supported by InnoDB. In case you want to convert an InnoDB table having foreign keys into MyISAM, you will encounter an error. Make sure to drop those constraints before converting. There are more differences between MyISAM and InnoDB that should be considered when you deal with these two storage engines.

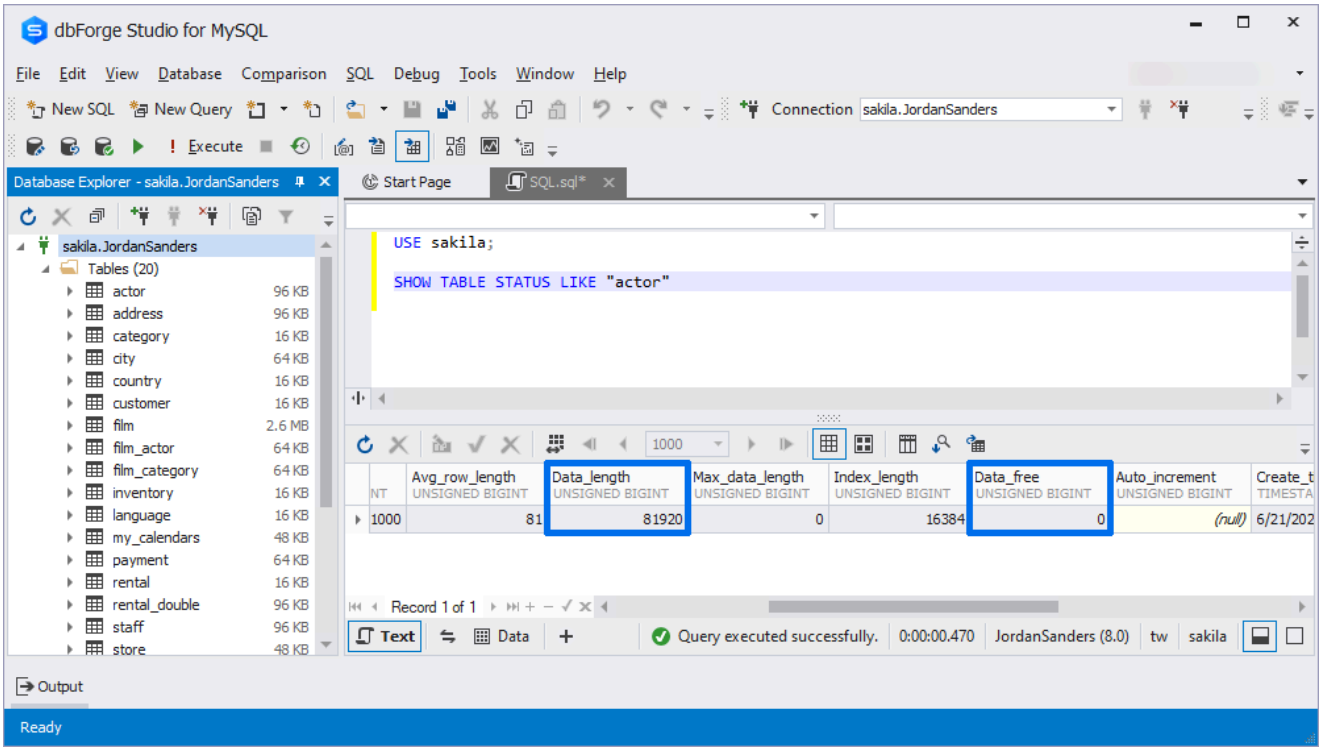
Optimize MyISAM tables

The primary function of myisamchk is to check, optimize, and repair MyISAM tables. This is crucial because frequent CRUD operations (CREATE, READ, DELETE, UPDATE) can lead to table corruption and a gradual decline in performance over time. dbForge Studio for MySQL includes a table maintenance tool that simplifies the process of identifying, analyzing, optimizing, and repairing tables.

To locate tables that require the administrator's attention, you can run the standard command in dbForge Studio for MySQL:

SHOW TABLE STATUS LIKE table_name;

This command provides detailed information about the table properties, including the total space occupied by the table and the total unused space (Data_length and Data_free columns, respectively). This helps users pinpoint tables that may be consuming excessive space and may be corrupted.



showtablestatus

This way, users can identify those tables that may take up too much space and be corrupted.

After detecting the MyISAM tables that require maintenance, you can apply the Studio's integrated table maintenance tool to those tables to fix the issues. To launch it, right-click the necessary table in Database Explorer and select **Table Maintenance**.

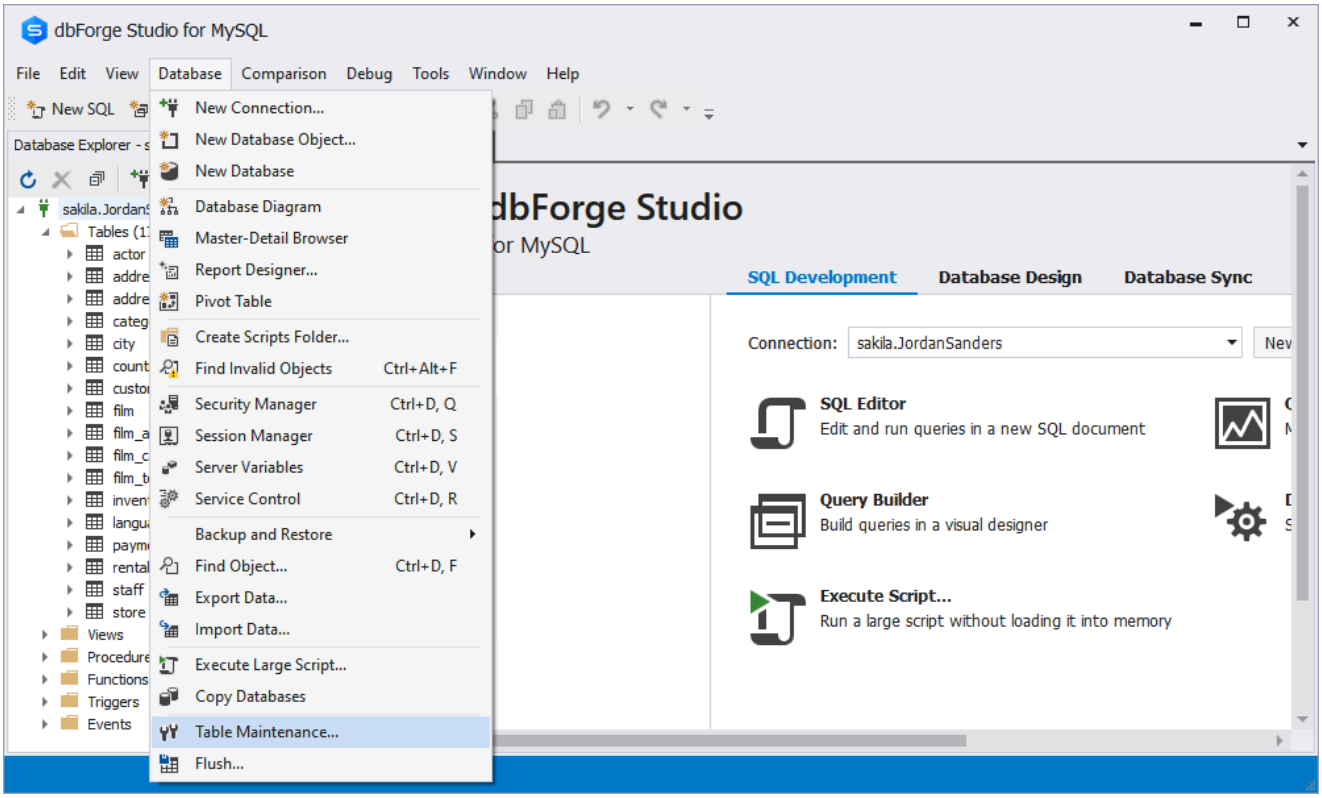


Table Maintenance

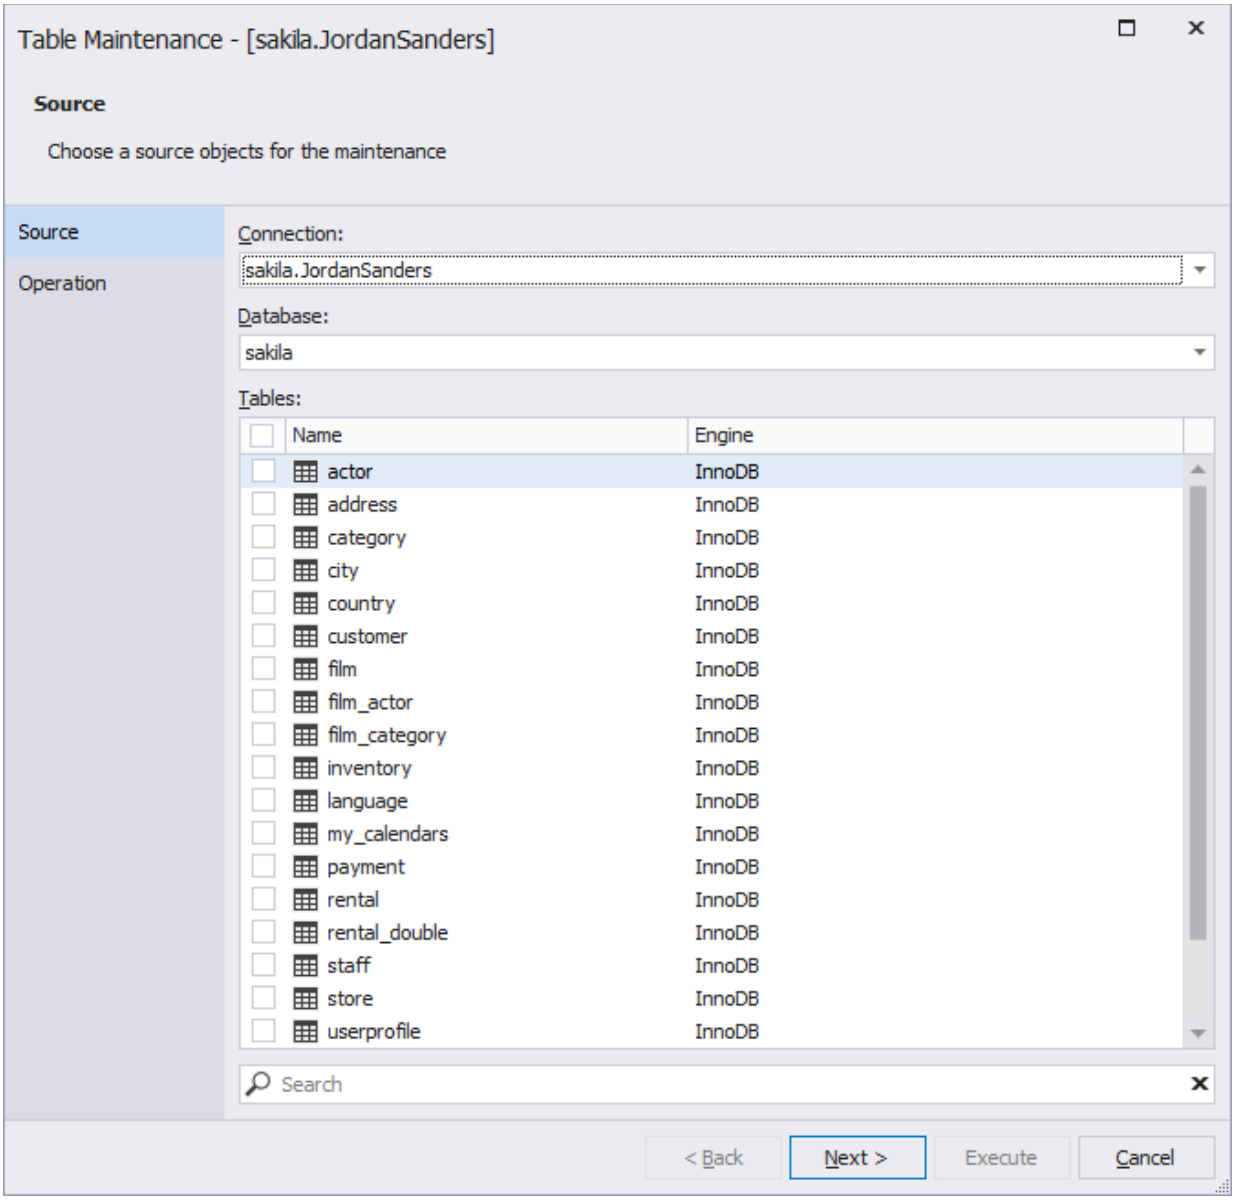
The table maintenance module offers the following options:



tablemaintenancewindow

- Analyze the table: This tool examines the key statistics of the table, helping to create more efficient query plans for optimal performance.
- Optimize the table: This option allows optimizing MyISAM tables for defragmentation, improving their performance.
- Check table errors: With this option, you can run diagnostic tests on tables, identifying and reporting all errors and corruption. It's worth noting that dbForge Studio provides flexible configuration for error checking, allowing users to determine the level of detail required. While a thorough scan for all possible errors may take time, it ensures that every issue is detected and reports 100% consistency.
- Checksum the table: This feature checks if the table has been modified, helping to maintain data integrity.
- Repair the table: This command is used to fix corrupted MyISAM tables. Applying this option may also recommend upgrading tables if necessary to rectify errors.

dbForge Studio streamlines all of these tasks with a single click. Users only need to specify the desired option and click **Execute**. This simplifies the process of maintaining MyISAM tables in MySQL databases.

More features of dbForge Studio for MySQL that can be applied to MyISAM tables and databases

The functionality of myisamchk is covered by one of many features available in dbForge Studio for MySQL. This multi-featured IDE offers a comprehensive toolset with flexible configuration and robust customization capacities to perform all database-related tasks in MySQL and MariaDB, no matter which database storage engine is used there. The following aspects are just several examples of the Studio's work:

- SQL Development: The functionality of this software client allows the users to construct and execute SQL queries and scripts, no matter the complexity, on databases using the MyISAM storage engine.
- Database Design: Users can both build database structures from scratch and modify existing ones, including creating and managing MyISAM tables and their respective indexes and keys.
- Database Administration: DBAs have access to essential tools for server connection management, performance monitoring, user account and privilege administration, and optimization and repair of tables using various storage engines.
- Data Management: Beyond basic data export and import tasks, dbForge Studio allows users to browse and edit data directly in the grid. You can also sort and filter data according to your specific needs.
- Backup and Restore: With support for MyISAM point-in-time backup and restore, the Studio can create backups of all types and restore them as needed. This ensures the safety, consistency, and stable performance of your databases.

Conclusion

Navigating the complexities of MyISAM storage engines doesn't have to be a daunting task. This article has provided you with an in-depth understanding of MyISAM clients and their integral role in MySQL and MariaDB database management. We've also showcased the unparalleled utility of dbForge Studio for MySQL, a one-stop IDE that simplifies everything from CRUD operations to advanced table maintenance. If you're keen on optimizing your database management processes, there's no better time to act.

Download a 30-day free trial of dbForge Studio to experience firsthand how this comprehensive tool can elevate your database operations to new heights.

myisam_ftdump

myisam_ftdump is a utility for displaying information about MyISAM FULLTEXT indexes. It will scan and dump the entire index, and can be a lengthy process.

If the server is running, make sure you run a FLUSH TABLES statement first.

Usage

```
myisam_ftdump <table_name> <index_num>
```

The table_name can be specified with or without the .MYI index extension.

The index number refers to the number of the index when the table was defined, starting at zero. For example, take the following table definition:

```
CREATE TABLE IF NOT EXISTS `employees_example` (
  `id` INT(11) NOT NULL AUTO_INCREMENT,
  `first_name` VARCHAR(30) NOT NULL,
  `last_name` VARCHAR(40) NOT NULL,
  `position` VARCHAR(25) NOT NULL,
  `home_address` VARCHAR(50) NOT NULL,
  `home_phone` VARCHAR(12) NOT NULL,
  `employee_code` VARCHAR(25) NOT NULL,
  `bio` text NOT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `employee_code` (`employee_code`),
  FULLTEXT (`bio`)
) ENGINE=MyISAM;
```

The fulltext index is `2`. The primary key is index `0`, and the unique key index `1`.

You can use *myisam_ftdump* to generate a list of index entries in order of frequency of occurrence as follows:

```
myisam_ftdump -c mytexttable 1 | sort -r
```

Options

Option	Description
-h, –help	Display help and exit.
-?, –help	Synonym for -h.
-c, –count	Calculate per-word stats (counts and global weights).
-d, –dump	Dump index (incl. data offsets and word weights).
-l, –length	Report length distribution.
-s, –stats	Report global stats.
-v, –verbose	Be verbose.

myisamchk Table Information

myisamchk can be used to obtain information about MyISAM tables, particularly with the *-d*, *-e*, *-i* and *-v* options.

Common options for gathering information include:

- myisamchk -d
- myisamchk -dv
- myisamchk -dvv
- myisamchk -ei
- myisamchk -eiv

The *-d* option returns a short description of the table and its keys. Running the option while the table is being updated, and with external locking disabled, may result in an error, but no damage is done to the table. Each extra *v* adds more output. *-e* checks the table thoroughly (but slowly), and the *-i* options adds statistical information,

-dvv output

The following table describes the output from the running myisamchk with the *-dvv* option:

Heading	Description
MyISAM file	Name and path of the MyISAM index file (without the extension)

Heading	Description
Record format	Storage format. One of packed (dynamic), fixed or compressed.
Character set	Default character set for the table.
File-version	Always 1.
Creation time	Time the data file was created
Recover time	Most recent time the file was reconstructed.
Status	Table status. One or more of analyzed, changed, crashed, open, optimized keys and sorted index pages.
Auto increment key	Index number of the table's auto-increment column. Not shown if no auto-increment column exists.
Last value	Most recently generated auto-increment value. Not shown if no auto-increment column exists.
Data records	Number of records in the table.
Deleted blocks	Number of deleted blocks that are still reserving space. Use OPTIMIZE TABLE to defragment.
Datafile parts	For dynamic tables, the number of data blocks. If the table is optimized, this will match the number of data records.
Deleted data	Number of bytes of unreclaimed deleted data, Use OPTIMIZE TABLE to reclaim the space.
Datafile pointer	Size in bytes of the data file pointer. The size of the data file pointer, in bytes.
Keyfile pointer	Size in bytes of the index file pointer.
Max datafile length	Maximum length, in bytes, that the data file could become.
Max keyfile length	Maximum length, in bytes, that the index file could become.
Recordlength	Space, in bytes, that each row takes.
table description	Description of all indexes in the table, followed by all columns
Key	Index number, starting with one. If not shown, the index is part of a multiple-column index.
Start	Where the index part starts in the row.
Len	Length of the index or index part. The length of a multiple-column index is the sum of the component lengths. Indexes of string columns is shorter than the full column length if only a string prefix is indexed.
Index	Whether an index value is unique or not. Either multip. or unique.
Type	Data type of the index of index part.
Rec/key	Record of the number of rows per value for the index or index part. Used by the optimizer to calculate query plans. Can be updated with myisamchk-a. If not present, defaults to 30.
Root	Root index block address.
Blocksize	Index block size, in bytes.
Field	Column number, starting with one. The first line will contain the position and number of bytes used to store NULL flags, if any (see Nullpos and Nullbit, below).

Heading	Description
Start	Column's byte position within the table row.
Length	Column length, in bytes.
Nullpos	Byte containing the flag for NULL values. Empty if column cannot be NULL.
Nullbit	Bit containing the flag for NULL values. Empty if column cannot be NULL.
Type	Data type - see the table below for a list of possible values.
Huff tree	Only present for packed tables, contains the Huffman tree number associated with the column.
Bits	Only present for packed tables, contains the number of bits used in the Huffman tree.

Data type	Description
constant	All rows contain the same value.
no endspace	No endspace is stored.
no endspace, not_always	No endspace is stored, and endspace compression is not always performed for all values.
no endspace, no empty	No endspace is stored, no empty values are stored.
table-lookup	Column was converted to an ENUM.
zerofill(N)	Most significant N bytes of the value are not stored, as they are always zero.
no zeros	Zeros are not stored.
always zero	Zero values are stored with one bit.

-eiv output

The following table describes the output from the running myisamchk with the *-eiv* option:

Heading	Description
Data records	Number of records in the table.
Deleted blocks	Number of deleted blocks that are still reserving space. Use OPTIMIZE TABLE to defragment.
Key	Index number, starting with one.
Keyblocks used	Percentage of the keyblocks that are used. Percentages is higher for optimized tables.
Packed	Percentage space saved from packing key values with a common suffix.
Max levels	Depth of the b-tree index for the key. Larger tables and longer key values result in higher values.
Records	Number of records in the table.
M.recordlength	Average row length. For fixed rows, is the actual length of each row.
Packed	Percentage saving from stripping spaces from the end of strings.
Recordspace used	Percentage of the data file used.
Empty space	Percentage of the data file unused.
Blocks/Record	Average number of blocks per record. Values higher than one indicate fragmentation. Use OPTIMIZE TABLE to defragment.
Recordblocks	Number of used blocks. Will match the number of rows for fixed or optimized tables.
Deleteblocks	Number of deleted blocks
Recorddata	Used bytes in the data file.
Deleted data	Unused bytes in the data file.
Lost space	Total bytes lost, such as when a row is updated to a shorter length.
Linkdata	Sum of the bytes used for pointers linking disconnected blocks. Each is four to seven bytes in size.

Examples

```
myisamchk -d /var/lib/mysql/test/posts

MyISAM file:         /var/lib/mysql/test/posts
Record format:       Compressed
Character set:       utf8mb4_unicode_ci (224)
Data records:                1680  Deleted blocks:                0
Recordlength:                2758
Using only keys '0' of 5 possibly keys

table description:
Key Start Len Index   Type
1   1     8   unique  ulonglong
2   2265  80  multip. varchar prefix
    63    80          varchar
    17    5           binary
    1     8           ulonglong
3   1231  8   multip. ulonglong
4   9     8   multip. ulonglong
5   387   764 multip. ? prefix
```

```
myisamchk -dvv /var/lib/mysql/test/posts

MyISAM file:         /var/lib/mysql/test/posts
Record format:       Compressed
Character set:       utf8mb4_unicode_ci (224)
File-version:        1
Creation time:       2015-08-10 16:26:54
Recover time:        2015-08-10 16:26:54
Status:              checked,analyzed,optimized keys
Auto increment key:              1  Last value:                  1811
Checksum:               2299272165
Data records:                 1680  Deleted blocks:                 0
Datafile parts:               1680  Deleted data:                   0
Datafile pointer (bytes):        6  Keyfile pointer (bytes):        6
Datafile length:           4298092  Keyfile length:            156672
Max datafile length: 281474976710654  Max keyfile length: 288230376151710719
Recordlength:                 2758
Using only keys '0' of 5 possibly keys

table description:
Key Start Len Index   Type                     Rec/key         Root  Blocksize
1   1     8   unique  ulonglong                      1                    1024
2   2265  80  multip. varchar prefix               336                    1024
    63    80          varchar                      187
    17    5           binary                         1
    1     8           ulonglong                      1
3   1231  8   multip. ulonglong                     10                    1024
4   9     8   multip. ulonglong                    840                    1024
5   387   764 multip. ? prefix                       1                    4096

Field Start Length Nullpos Nullbit Type                          Huff tree  Bits
1     1     8                     zerofill(6)                           1     9
2     9     8                     zerofill(7)                           1     9
3     17    5                                                           1     9
4     22    5                                                           1     9
5     27    12                    blob                                  2     9
6     39    10                    blob                                  3     9
7     49    4                     always zero                           1     9
8     53    10                    blob                                  1     9
9     63    81                    varchar                               4     9
10    144   81                    varchar                               5     5
11    225   81                    varchar                               5     5
12    306   81                    varchar                               1     9
13    387   802                   varchar                               6     9
14    1189  10                    blob                                  1     9
15    1199  10                    blob                                  7     9
16    1209  5                                                           1     9
17    1214  5                                                           1     9
18    1219  12                    blob                                  1     9
19    1231  8                     no zeros, zerofill(6)                 1     9
20    1239  1022                  varchar                               7     9
21    2261  4                     always zero                           1     9
22    2265  81                    varchar                               8     8
23    2346  402                   varchar                               2     9
24    2748  8                     no zeros, zerofill(7)                 1     9

myisamchk

myisamchk

myisamchk is a command line tool for checking, repairing and optimizing non-partitioned MyISAM tables.

myisamchk is run from the command line as follows:

```
myisamchk [OPTIONS] tables[.MYI]
```

The full list of options are listed below. One or more MyISAM tables can be specified. MyISAM tables have an associated .MYI index file, and the table name can either be specified with or without the .MYI extension. Referencing it with the extension allows you to use wildcards, so it's possible to run myisamchk on *all* the MyISAM tables in the database with `*.MYI`.

The path to the files must also be specified if they're not in the current directory.

> **Important:**
>
> myisamchk should not be run while anyone is accessing any of the affected tables. It is also best to make a backup before running.

With no options, myisamchk simply checks your table as the default operation.

The following options can be set while passed as command line options to myisamchk, or set with a [myisamchk] section in your my.cnf file.

General Options

Option	Description
-H, –HELP	Display help and exit. Options are presented in a single list.
-?, –help	Display help and exit. Options are grouped by type of operation.
-# options, –debug=options	Write a debugging log. A typical debug options string is `d:t:o,file_name`. The default is `d:t:o,/tmp/myisamchk.trace`. (Available in debug builds only)
-t path, –tmpdir=path	Path for temporary files. Multiple paths can be specified, separated by colon (:) on Unix and semicolon (;) on Windows. They are used in a round-robin fashion. If not set, the TMPDIR environment variable is used.
-s, –silent	Only print errors. One can use two -s (-ss) to make myisamchk very silent.
-v, –verbose	Print more information. This can be used with –description and –check. Use many -v for more verbosity.
-V, –version	Print version and exit.
-w, –wait	If table is locked, wait instead of returning an error.
–print-defaults	Print the program argument list and exit.
–no-defaults	Don't read default options from any option file.
–defaults-file=filename	Only read default options from the given file filename, which can be the full path, or the path relative to the current directory.
–defaults-extra-file=filename	Read the file filename, which can be the full path, or the path relative to the current directory, after the global files are read.
–defaults-group-suffix=str	Also read groups with a suffix of str. For example, –defaults-group-suffix=x would read the groups [myisamchk] and [myisamchk_x]

The following variables can also be set by using *–var_name=value*, for example *–ft_min_word_len=5*

Variable	Default Value
decode_bits	9
ft_max_word_len	version-dependent
ft_min_word_len	4
ft_stopword_file	built-in list
key_buffer_size	1044480
key_cache_block_size	1024
myisam_block_size	1024
myisam_sort_buffer_size	134216704
myisam_sort_key_blocks	16
read_buffer_size	262136
sort_buffer_size	134216704
sort_key_blocks	16
stats_method	nulls_unequal
write_buffer_size	262136

Checking Tables

If no option is provided, myisamchk will perform a check table. It is possible to check MyISAM tables without shutting down or restricting access to the server by using CHECK TABLE instead.

The following check options are available:

Option	Description
-c, –check	Check table for errors. This is the default operation if you specify no option that selects an operation type explicitly.
-e, –extend-check	Check the table VERY thoroughly. Only use this in extreme cases as it may be slow, and myisamchk should normally be able to find out if the table has errors even without this switch. Increasing the key_buffer_size can help speed the process up.
-F, –fast	Check only tables that haven't been closed properly.
-C, –check-only-changed	Check only tables that have changed since last check.
-f, –force	Restart with '-r' (recover) if there are any errors in the table. States is updated as with '–update-state'.
-i, –information	Print statistics information about the table that is checked.
-m, –medium-check	Faster than extend-check, but only finds 99.99% of all errors. Should be good enough for most cases.
-U –update-state	Mark tables as crashed if you find any errors. This should be used to get the full benefit of the –check-only-changed option, but you shouldn´t use this option if the mariadbd server is using the table and you are running it with external locking disabled.
-T, –read-only	Don't mark table as checked. This is useful if you use myisamchk to check a table that is in use by some other application that does not use locking, such as mariadbd when run with external locking disabled.

Repairing Tables

It is also possible to repair MyISAM tables by using REPAIR TABLE.

The following repair options are available, and are applicable when using '-r' or '-o':

Option	Description
-B, –backup	Make a backup of the .MYD file as 'filename-time.BAK'.
–correct-checksum	Correct the checksum information for table.
-D len, –data-file-length=#	Max length of data file (when recreating data file when it's full).
-e, –extend-check	Try to recover every possible row from the data file. Normally this will also find a lot of garbage rows; Don't use this option if you are not totally desperate.
-f, –force	Overwrite old temporary files. Add another –force to avoid 'myisam_sort_buffer_size is too small' errors. In this case we will attempt to do the repair with the given myisam_sort_buffer_size and dynamically allocate as many management buffers as needed.
-k val, –keys-used=#	Specify which keys to update. The value is a bit mask of which keys to use. Each binary bit corresponds to a table index, with the first index being bit 0. 0 disables all index updates, useful for faster inserts. Deactivated indexes can be reactivated by using myisamchk -r.
–create-missing-keys	Create missing keys. This assumes that the data file is correct and that the number of rows stored in the index file is correct. Enables –quick
–max-record-length=#	Skip rows larger than this if myisamchk can't allocate memory to hold them.
-r, –recover	Can fix almost anything except unique keys that aren't unique (a rare occurrence). Usually this is the best option to try first. Increase myisam_sort_buffer_size for better performance.
-n, –sort-recover	Forces recovering with sorting even if the temporary file would be very large.

Option	Description
-p, –parallel-recover	Uses the same technique as '-r' and '-n', but creates all the keys in parallel, in different threads.
-o, –safe-recover	Uses old recovery method; Slower than '-r' but uses less disk space and can handle a couple of cases where '-r' reports that it can't fix the data file. Increase key_buffer_size for better performance.
–character-sets-dir=directory_name	Directory where the character sets are installed.
–set-collation=name	Change the collation (and by implication, the character set) used by the index.
-q, –quick	Faster repair by not modifying the data file. One can give a second '-q' to force myisamchk to modify the original datafile in case of duplicate keys. NOTE: Tables where the data file is corrupted can't be fixed with this option.
-u, –unpack	Unpack file packed with myisampack.

Other Actions

Option	Description
-a, –analyze	Analyze distribution of keys. Will make some joins faster as the join optimizer can better choose the order in which to join the tables and which indexes to use. You can check the calculated distribution by using '–description –verbose table_name' or SHOW INDEX FROM table_name.
–stats_method=name	Specifies how index statistics collection code should treat NULLs. Possible values of name are "nulls_unequal" (default), "nulls_equal" (emulate MySQL 4.0 behavior), and "nulls_ignored".
-d, –description	Print some descriptive information about the table. Specifying the –verbose option once or twice produces additional information.
-A [value], –set-auto-increment[=value]	Force auto_increment to start at this or higher value. If no value is given, then sets the next auto_increment value to the highest used value for the auto key + 1.
-S, –sort-index	Sort the index tree blocks in high-low order. This optimizes seeks and makes table scans that use indexes faster.
-R index_num, –sort-records=#	Sort records according to the given index (as specified by the index number). This makes your data much more localized and may speed up range-based SELECTs and ORDER BYs using this index. It may be VERY slow to do a sort the first time! To see the index numbers, SHOW INDEX displays table indexes in the same order that myisamchk sees them. The first index is 1.
-b offset, –block-search=offset	Find the record to which a block at the given offset belongs.

For more, see Memory and Disk Use With myisamchk.

Examples

Check all the MyISAM tables in the current directory:

```
myisamchk *.MYI
```

If you are not in the database directory, you can check all the tables there by specifying the path to the directory:

```
myisamchk /path/to/database_dir/*.MYI
```

Check all tables in all databases by specifying a wildcard with the path to the MariaDB data directory:

```
myisamchk /path/to/datadir/*/*.MYI
```

The recommended way to quickly check all MyISAM tables:

```
myisamchk --silent --fast /path/to/datadir/*/*.MYI
```

Check all MyISAM tables and repair any that are corrupted:

```
myisamchk --silent --force --fast --update-state \
  --key_buffer_size=64M --sort_buffer_size=64M \
  --read_buffer_size=1M --write_buffer_size=1M \
/path/to/datadir/*/*.MYI
```

This page is licensed: CC BY-SA / Gnu FDL

myisamlog

`myisamlog` processes and returns the contents of a MyISAM log file.

Invoke `myisamlog` like this:

```
shell> myisamlog [options] [log_file [tbl_name] ...]
shell> isamlog [options] [log_file [tbl_name] ...]
```

The default operation is update (`-u`). If a recovery is done (`-r`), all writes and possibly updates and deletes are done and errors are only counted.
The default log file name is `myisam.log` for `myisamlog` and `isam.log` for `isamlog` if no `log_file` argument is given. If tables are named on the command line, only those tables are updated.

`myisamlog` supports the following options:

Option	Description
-?, -I	Display a help message and exit.
-c N	Execute only N commands.
-f N	Specify the maximum number of open files.
-i	Display extra information before exiting.
-o offset	Specify the starting offset.
-p N	Remove N components from path.
-r	Perform a recovery operation.
-R record_pos_file record_pos	Specify record position file and record position.
-u	Displays update operations.
-v	Verbose mode. Print more output about what the program does. This option can be given multiple times (-vv, -vvv) to produce more and more output.
-w write_file	Specify the write file.
-V	Display version information.

myisampack

myisampack

`myisampack` is a tool for compressing MyISAM tables. The resulting tables are read-only, and usually about 40% to 70% smaller. It is run as follows:

```
myisampack [options] file_name [file_name2...]
```

The `file_name` is the `.MYI` index file. The extension can be omitted, although keeping it permits wildcards, such as:

```
myisampack *.MYI
```

…to compress all the files.

`myisampack` compresses each column separately, and, when the resulting data is read, only the individual rows and columns required need to be decompressed, allowing for quicker reading.

Once a table has been packed, use myisamchk -rq (the quick and recover options) to rebuild its indexes.

`myisampack` does not support partitioned tables or vector indexes.

> **Important:**
>
> Do not run myisampack if the tables could be updated during the operation, and skip_external_locking has been set.

Options

The following variables can be set while passed as command line options to `myisampack`, or set with a `[myisampack]` section in your my.cnf file.

Option	Description
-b, –backup	Make a backup of the table as table_name.OLD.
–character-sets-dir=name	Directory where character sets are.
-	
## , –debug[=name]	Output debug log. Often this is ‘d:t:o,filename’.
-f, –force	Force packing of table even if it gets bigger or if tempfile exists.
-j, –join=name	Join all given tables into ‘new_table_name’. All tables must have identical layouts.
-?, –help	Display help and exit.
-s, –silent	Only write output when an error occurs
-T, –tmpdir=name	Use temporary directory to store temporary table.
-t, –test	Don’t pack table, only test packing it.
-v, –verbose	Write info about progress and packing result. Use multiple -v flags for more verbosity.
-V, –version	Output version information and exit.
-w, –wait	Wait and retry if table is in use.

Uncompressing

To uncompress a table compressed with `myisampack`, use the myisamchk -u option.

Examples

```
> myisampack /var/lib/mysql/test/posts
Compressing /var/lib/mysql/test/posts.MYD: (1680 records)
- Calculating statistics
- Compressing file
37.71%
> myisamchk -rq /var/lib/mysql/test/posts
- check record delete-chain
- recovering (with sort) MyISAM-table '/var/lib/mysql/test/posts'
Data records: 1680
- Fixing index 1
- Fixing index 2
```

About MariaDB Software

MariaDB is an open-source, multi-threaded, relational database management system, released under the GNU Public License (GPL). MariaDB's lead developer is Michael "Monty" Widenius, who is one of the founders of MySQL AB.

There are millions of installations of MariaDB worldwide, and thousands of downloads a day of MariaDB installation software. The success of MariaDB as a leading database is due not only to open source, but also its reliability, performance, and features.

Features

Many features contribute to MariaDB's standing as a database system. Its speed is one of its most prominent features. MariaDB is remarkably scalable, and is able to handle tens of thousands of tables and billions of rows of

data. It can also manage small amounts of data quickly and smoothly, making it convenient for small businesses or personal projects.

Another feature that sets it apart from its predecessors is a particular focus on security. When critical security issues are discovered, our engineers immediately prepare and distribute a new release of MariaDB, as quickly as possible. The MariaDB team works closely with the Mitre Organization to ensure all security issues are promptly reported and documented in sufficient detail. These details are typically released after the new release has been published.

MariaDB's built-in functions include ones for manipulating and formatting text, business and statistical calculations, recording chronological information, as well as specialty features such ones related to GPS mapping.

Usage

We strive to develop a database system that works easily on the web and has one of the fastest connectors. Thanks to the fact that we use threads, we can handle much higher loads than other database systems. We have always striven to adapt to new hardware and to optimize the software for all commonly used systems and methods of deployment. Because we're continuously improving the software, we're able to provide a new release each month and a new version every year. That's an indication that things are happening and improving regularly.

In addition to web usage, MariaDB can be used for stand-alone applications ranging from enterprise transactional and analytical systems down to mobile devices, embedded with other software. MariaDB works in the cloud or on premise.

Due to its focus on performance and based on its threading model, MariaDB features the scale out technologies necessary for when your site or application experiences major spikes in traffic or rapid growth in business.

Security

With encryption that we've introduced in recent versions of MariaDB, you can be assured that your databases is secure — by default. Most other database systems don't have encryption by default.

Many organizations are leery about using commercial database software because they don't know for sure if the compiled code contains back-doors for accessing the data or some special way in which the software is using encryption that could allow a hacker to get at their data. Since MariaDB is open-source, governments and other organizations know that their databases are secure. Nothing is hidden.

Integration

The critical software in any database management system is its storage engine, which manages queries and interfaces between a user's SQL statements and the database's back-end storage. MariaDB offers several storage engines with different advantages. Some are transaction-safe storage engines that allow for rollback of data.

MariaDB also offers full integration with Galera cluster — an add-on for MariaDB for running multiple database servers for better performance and high availability. This is just one of many examples of how MariaDB integrates well with other software and systems. Such integration and MariaDB new encryption features have made it the premier database.

Version & Release Schedule

MariaDB is known for rapid and stable improvements. Each new release comes with speed and stability improvements, as well as new features. Current and development versions of MariaDB (and many previous versions) can be downloaded from the MariaDB Downloads Directory. There is also a yum repository for installing easily MariaDB and related software. Use the yum repository tool to configure your server.

See also the MariaDB maintenance policy.

MariaDB makes updates to active releases about once a month. The MariaDB Foundation provides a road map, which will give you information on when to expect the next release of MariaDB.

Learning MariaDB

If you're developing a career as a computer programmer, a web developer, or a similar role in computer technology, learning MariaDB will prove useful in your career. Many businesses develop and maintain custom software with MariaDB and the similar software. Additionally, many of the most popular web sites and software use MariaDB for their database — or they use another SQL database system that you can learn easily once you understand MariaDB.

It's highly likely that, for any job to which you apply or take as a database developer or administrator or as a web site developer, you is required to know or you isnefit from knowing MariaDB. Therefore, learning MariaDB is a good foundation for your career in computer technology. These documentation pages are your best resource for learning MariaDB in detail.

Applications Supporting MariaDB

> **Note:**
>
> The projects listed on this page are third-party software, not developed or maintained by MariaDB. MariaDB doesn't test, validate, or support them. Refer to each project's own documentation and license terms.

This page lists projects which officially implement MariaDB's enhanced features, or state that they work with MariaDB. If you know of a project which officially supports MariaDB and it isn't listed here, please let us know in the comments.

> **Note:**
>
> Note: Every project we know of which works with MySQL also works with MariaDB. This page is just to point out projects which officially support MariaDB (e.g. by mentioning MariaDB in their documentation or setup instructions).

Supports Enhanced MariaDB Features

- dbForge Studio is a versatile and feature-rich IDE designed for MySQL and MariaDB professionals. It fully supports all individual features of MariaDB, such as support for Packages and Sequences, and other specificities.
- Dynamic Active Record - The yii2-dynamic-ar extension uses MariaDB dynamic columns to add NoSQL-like documents to Yii 2 Framework's Active Record ORM.
- ocelotgui - supports MariaDB 10.2 window functions.
- Shard-query has special support for MariaDB 10.0 features
- SQL Maestro for MySQL is a database management tool that provides direct support for a number of MariaDB features like roles, check constraints, and virtual columns.

Officially Supports MariaDB

- Alfresco - Alfresco is for Enterprise Content Management and Business Process Management and it supports running with MariaDB Server.
- Bitbucket by Atlassian
- Codeship

- Dataedo - Database documentation tool with rich-text fields and ERD creator.
- DBeaver - free convenient cross-platform and cross-database Java GUI client which supports special MySQL/MariaDB features.
- dbForge Edge is a multidatabase solution for MariaDB/MySQL, SQL Server, Oracle, and PostgreSQL. It includes a full-featured IDE for MariaDB, covering all key tasks in database development, design, management, and administration.
- dbForge Compare Bundle - contains two separate tools, dbForge Schema Compare and dbForge Data Compare.
- dbForge Data Compare - data comparison and synchronization tool.
- dbForge Data Generator - a visual tool for generation of large volumes of meaningful test table data.
- dbForge Documenter - a handy MariaDB documentation tool that automatically generates documentation in HTML, PDF, and MARKDOWN file formats.
- dbForge Query Builder is a GUI tool designed to create any MySQL and MariaDB queries in a visual mode. The drag-and-drop feature ensures the easy and accurate building of even the most sophisticated statements.
- dbForge Schema Compare - a tool for comparison and sync of DDL differences between database objects
- DbVisualizer - Cross-platform universal database tool, supports MariaDB/MySQL specific features
- dotConnect for MySQL - data provider for MariaDB and MySQL built over ADO.NET with support for .NET Core 1.x and 2.0
- Devart ODBC Driver for MySQL - ODBC driver for direct access to MariaDB or MySQL database via TCP/IP without database client
- Devart Excel Add-ins for MySQL - connect Microsoft Excel to MariaDB and MySQL and work with data like with usual Excel worksheets
- Drupal
- ERBuilder Data Modeler - Data modeling tool for multiple databases platforms including MariaDB, MySQL, and more. Free and commercial versions available.
- eZ
- Flyway
- Friendica
- Geeklog (installation requirements)
- ImpressCMS,a community-developed content-management system
- Jelastic - Java in the cloud
- Kajona³ - Open Source Content Management Framework (support announcement)
- Matomo – Matomo is an open-source web analytics platform that prioritizes user privacy and data ownership, providing a powerful, GDPR-compliant alternative to Google Analytics.
- MediaWiki (installation guide)
- MicroStrategy
- Moodle
- Moon Modeler - database design tool for MariaDB
- Mroonga
- mycli - command line interface for MariaDB with auto-completion and syntax highlighting.
- MySQL Data Access Components - the library of components for direct access to MariaDB and MySQL from Delphi
- Neor Profile SQL
- ownCloud (documentation)
- phpMyAdmin
- Plone (documentation)

- Querious - Mac OS X database administration tool
- RAD Studio (Embarcadero) supports MariaDB from RAD Studio 10.2 Tokyo
- Replication Manager for MariaDB and MySQL - High Availability solution to manage MariaDB Server 10.0+ GTID-based replication topologies
- SafeNet ProtectFile rom Gemalto
- SaltOS
- sequelize - Dialect object-relationship-mapper for node.js.
- Skyvia - Cloud service for data integration, management and backup
- SQLTool Pro
- SSIS Data Flow Components for MySQL - set of components for SQL Server Integration Services packages that allow loading data from MariaDB and MySQL in SSIS Data Flows
- Talend
- TransProCloud
- 12PRESS - an online FLOSS meeting and events schedule presentation platform for 12-Step recovery fellowships (AA, NA, Alanon, etc.), their regions and area service committees, etc.
- Travis CI
- UI Bakery - Low-code development platform for building web applications on top of MariaDB data (integration page, documentation)
- Universal Data Access Components - the library of non-visual cross-database data access components for Delphi that includes support for MariaDB and MySQL
- Valentina Reports & Reports Server - Reports Server on macOS, Windows and Linux and deployable app solution using MariaDB as data source
- Valentina Studio - Database GUI on macOS, Windows and Linux. Free & Pro versions.
- WordPress (glossary from install documentation)
- WPИ-XM
- XAMPP (announcement)
- Wercker
- Yii (Yii 1.1 guide and Yii 2.0 guide)
- Zarafa 7.2 onwards comes with MariaDB support release notes
- Zend Framework (Zend_Db_Adapter)

About the MariaDB Foundation

The MariaDB Foundation ensures that there is not just one person or one company driving MariaDB/MySQL development. It is the custodian of the MariaDB code and guardian of the MariaDB community.

The MariaDB Foundation is the owner of the main MariaDB server project and owns mariadb.org. This ensures that the official MariaDB development tree will always be open for the MariaDB developer community.

Goals

That MariaDB be actively developed in the community and to:

- Increase adoption of MariaDB.

- Ensure sustainable high-quality efforts to build, test and distribute MariaDB.
- Ensure that community patches are reviewed and adopted.
- Guarantee a community voice and define development rules.
- Keep MariaDB compatible with MySQL.
- Maintain mariadb.org.

If you are using MariaDB in production and want to ensure that MariaDB is always actively developed, then you should sponsor or become a member of the MariaDB foundation!.

It's the MariaDB Foundation that ensures that all community patches, including MySQL source code, are merged into MariaDB. It also does the builds and QA of MariaDB and provides a lot of the MariaDB documentation.

We are very grateful to our current members and sponsors who are making this work possible!

More information about the Foundation can be found on the MariaDB foundation website.

Client Libraries

See Connect and Query.

Connect to and query MariaDB using a connector (from an application) or a client (interactively or from scripts).

See Proxy Protocol Support.

Proxy protocol support, which lets proxy programs relay client IP addresses to MariaDB Server.

See Client/Server Protocol.

Pointers to the MariaDB client/server protocol reference documentation.

This page is licensed: CC BY-SA / Gnu FDL

Connect and Query

Database connections are made using a **connector** (from an application) or a **client** (interactively or from scripts).

Clients and connectors listed here are supported under MariaDB Corporation Engineering Policies.

Clients and connectors listed here are compatible with:

- MariaDB database products (including Enterprise Server and MaxScale)
- MariaDB Community Server

MariaDB Connectors

MariaDB Connectors are available for many popular programming languages.

Programming Language / Interface	Connector
C	MariaDB Connector/C
C++	MariaDB Connector/C++
Java - JDBC	MariaDB Connector/J
Java - R2DBC	MariaDB Connector/R2DBC
JavaScript	MariaDB Connector/Node.js
ODBC	MariaDB Connector/ODBC
Python	MariaDB Connector/Python

MariaDB Client

MariaDB Client can be used interactively or within scripts.

MariaDB Client is included with distributions of MariaDB database products.

Compatible third-party clients exist but are not listed here.

Executable Filename	Purpose
mariadb, mysql	Connect from the command line

For additional information about MariaDB Client, see MariaDB Client.

Tools and Utilities

Tools and utilities listed here are included with distributions of MariaDB database products and make a client connection.

Command-Line Executable	Purpose
mariadb-admin, mysqladmin	Check configuration and current status
mariadb-backup, mariadb-backup	Create and restore physical backups (including Aria, InnoDB, MyISAM, MyRocks)
mariadb-binlog, mysqlbinlog	Read binary logs or relay logs
mariadb-check, mysqlcheck	Perform table maintenance operations
mariadb-dump, mysqldump	Create logical backups
mariadb-import, mysqlimport	Load table data from CSV, TSV, and other text file formats
mariadb-show, mysqlshow	Display databases, tables, table columns, indexes
mariadb-slap, mysqlslap	Generate client load for testing

Business Intelligence (BI)

MariaDB database products are accessible from business intelligence (BI) platforms, including:

BI Platform	Detail
Microsoft Power BI	MariaDB Direct Query Adapter for Microsoft Power BI enables Microsoft Power BI Desktop users to remotely connect to and query their MariaDB database, including on MariaDB MariaDB Cloud, without downloading the entire data set to their local machine.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Proxy Protocol Support

The proxy protocol allows proxy programs to relay the IP addresses of the clients to the server programs. It is important in the case of MariaDB, since IP information is actually a part of user identity.

How Proxy Protocol Works

As per the proxy protocol specification, the connecting client can prefix its first packet with a proxy protocol header. The server will parse the header and assume the client's IP address is the one set in the proxy header.

For example, if a client sends the proxy header (V1, text) which is "PROXY TCP4 192.168.0.1 192.168.0.11 56324 443\r\n", the server, after parsing, assumes the client's IP is 192.168.0.1

MariaDB server understands both Version 1 (text) and Version 2 (binary) of the proxy header.

If the protocol specified by the version 1 header is "UNKNOWN", the MariaDB server will treat the connection as if the proxy protocol was disabled. This can be used when a valid proxy protocol header is needed, but there is no

client to proxy, for example, when a proxy does a health check.

Enabling Proxy Protocol in MariaDB Server

To enable use of the proxy protocol, it is necessary to specify subnetworks that are allowed to send proxy headers, using the proxy-protocol-networks server variable.

proxy-protocol-networks is either a comma-separated list of (sub) networks or IP addresses. One can also use 'localhost' in this list, which means Unix domain socket/named pipe/shared memory connections are allowed as well. Or proxy-protocol-networks can be set to *, meaning that proxy headers are allowed from any client.

> **Warning:**
>
> Note that a client running on a host within an allowed proxy network or an IP address can itself pretend to be connected from any IP address whatsoever and thus can possibly impersonate other users. Generally, you should limit shell access to proxy hosts to a minimum. And remember, with `proxy-protocol-networks=*` every host is a proxy host.

Example in my.ini/my.cnf

```
proxy-protocol-networks=::1, 192.168.0.0/16, localhost
```

allows IPv6 connections from local machine ::1, from IP addresses starting with 192.168, and from connections made with Unix domain sockets or named pipes.

Client-Side Support for Proxy Protocol

Since the functionality is suited only to very specific proxy-like programs, most client APIs do not provide support for sending proxy headers. One exception is Connector/C version 3 or later. One can now use mysql_optionsv():

```
mysql_optionsv(mysql, MARIADB_OPT_PROXY_HEADER, header,  header_size)
```

prior to mysql_real_connect() or mysql_connect(), to send the header. In the call above, `_header_` is the proxy header with the type `void *`, and `_header_size_` is its size in bytes (type is `size_t`).

Example

```
const char *hdr="PROXY TCP4 192.168.0.1 192.168.0.11 56324 443\r\n";
mysql_optionsv(mysql, MARIADB_OPT_PROXY_HEADER, hdr,  strlen(hdr));
```

Using Proxy Protocol with MariaDB MaxScale

If you want to use proxy protocol with MaxScale:

- Add the IP address of the MaxScale server to proxy-protocol-networks
- In `maxscale.cnf`, add the proxy_protocol parameter for all configured servers

Once configured, MaxScale will proxy the credentials from the client to the server.

Downloads

Latest Packages

Tarballs, source and binaries (Linux and Windows), and packages for some Linux distributions are available at mariadb.org/download.

We hope that interested community package maintainers will step forward, as others already have, to build packages for their distributions. We ask for strict adherence to your packaging system's best practices and invite you to create a bug report if our project impedes this in any way.

Instructions how to install the packages can be found here. See the Includes MariaDB documentation page for a list of which Linux distributions that include MariaDB.

Pre-Release Binaries

Binaries from our Buildbot system at buildbot.mariadb.org are available as containers on quay.io/mariadb-foundation/mariadb-devel:{major version}. Tags available are listed here.

These haven't passed through a full release process; however changes there have been reviewed and are considered complete by the server developers. Its recommend to use these for testing.

Getting the Source

The mariadb.org/download download page contains the source for all released binaries. You can find the latest source code at server

To retrieve the code, the Git source control software offers the path of least resistance. If you are unfamiliar with git, please refer to the git documentation for an understanding of version control with git.

For instructions on creating a local branch of MariaDB, see the Getting the MariaDB Source Code page.

See the Generic Build Instructions page for general instructions on compiling MariaDB from the source.
The source page has links to platform and distribution-specific information, including information on how we build the release packages.

Old Versions

Running the most recent MariaDB version is generally the best choice. Note that there are long-term releases, maintained for five years, short-term releases, maintained for one year, and rolling releases. However, some organizations still use old or very old versions of MariaDB. An upgrade would probably require important changes in their applications, and sometimes they don't even have the sources of those applications.

mariadb.org/download/ contains all historical releases.

There are source and repositories there. To use repositories see the following link:

- RHEL and RPM distros
- Debian/Ubuntu based distos

It is also possible to access Docker Official Images of MariaDB back to 5.5.40 when it became an official image (available tags).

See MariaDB Source Code.

Check out the MariaDB Server source code from GitHub with Git, including how to select a specific branch or release.

See MariaDB RPM Packages.

Where to find MariaDB RPM packages for Fedora and other distributions, plus the YUM repository configuration tool.

See Mirror Sites for MariaDB.

How MariaDB is distributed through mirror sites, and how to volunteer your server as an official MariaDB mirror.

See Where to Download MariaDB.

Where to download MariaDB tarballs, binaries, and distribution packages, covering the latest releases and historical versions.

This page is licensed: CC BY-SA / Gnu FDL

MariaDB Source Code

Checking out the Source with Git

The MariaDB source is hosted on GitHub: server. You can get a copy with:

```
git clone https://github.com/MariaDB/server mariadb-server
```

If you want a source tarball for a specific released MariaDB version, you can find it at downloads.mariadb.org.

At any given time, developers is working on their own branches locally or on GitHub, with the main MariaDB branches receiving pushes less often.

The main MariaDB branches are:

- main
- 13.0
- 12.3
- 11.8
- 11.4
- 10.11
- 10.6

Source repositories for the MariaDB Connectors are:

- MariaDB Connector/C
- MariaDB Connector/C++
- MariaDB Connector/J
- MariaDB Connector/Node.js
- MariaDB Connector/ODBC
- MariaDB Connector/Python

See also:

- Using git page for instructions on how to use git to check out the source code and switch between the various branches.
- Compiling MariaDB from source

> **Important:**
>
> The rest of this page contains information on checking out the MariaDB source from Launchpad. As the current source is now on GitHub, the information is mainly of historical interest and not useful for current development.

The instructions on this page will help you download your own local branch of the MariaDB source code repository with the full revision history. If you want a tarball of the source without the revision history, see the MariaDB download page.

Checking out the Source with Bazaar

If you simply want to browse the source code, you can do so from maria.

Prerequisites

You need Bazaar for revision control.

Instructions

1. Prepare a directory to keep your MariaDB code in:

```
mkdir $repo

# where $repo is some directory (ex: ~/repos)

cd $repo
bzr init-repo maria

# this creates ~/repos/maria
```

1. Get a clean local copy of the Maria repo with:

```
cd $repo/maria

# (ex: ~/repos/maria)

bzr branch lp:maria trunk
```

The above will give you the latest stable MariaDB version.
If you want to get another release use lp:maria/5.2, lp:maria/5.3…
For a complete list, go to Launchpad and choose 'Code' from the top menu on the page.

- Note: The initial branch operation can take a long time depending on the speed of your Internet connection and the load on launchpad. For this initial branch you need to download over a gigabyte of data.
- Note: Bzr is written in Python and very slow for initial checkout. Even on a fast connection, expect to need 1-2 GByte of RAM and possibly several CPU hours for the checkout.

1. If you get an error like:

```
bzr: ERROR: Unknown repository format: 'Bazaar RepositoryFormatKnitPack6 (bzr 1.9)'
```

then the version of bzr you are using is too old. Using version 1.12 or higher will fix this error.

1. If you have upgraded your bzr and are unable to successfully branch from launchpad, try using the source tree tarball (below) instead.
2. You can see the current history with:

```
cd $repo/maria/trunk
bzr log | less
```

1. If you are going to be hacking on the MariaDB source code. See the Contributing Code page for help.
2. If you just want to compile MariaDB at this point, see the Compiling MariaDB page.

Source Tree Tarball

For those that have trouble branching MariaDB from Launchpad we have created a tarball of a complete repository of the MariaDB tree.

Prerequisites

You need Bazaar to work with the repository.

Using the Source Tree Tarball

1. Download the mariadb-shared-repo.tgz file from one of the MariaDB mirrors.

- The file is 267MB, so the download may take a long time to complete depending on your Internet connection.

1. The .tgz file contains a .bzr directory. The parent directory of this .bzr directory is (or becomes) a shared repository containing the
   MariaDB source code. It is recommended to create a new directory for this, so the next step is to create a directory to house the repository. Call this directory anything you like (“maria”, “mariadb”,
   “my”, “src”, etc…). Once created, cd into the directory and untar the file. Here is an example using the name “mariadb” for the new directory, with the directory located in a directory called “src” in the home directory of the current user, and the mariadb-shared-repo.tgz file located in a directory named Downloads (also in the current user’s home directory):

```
mariadbdir="mariadb"
downloadsdir="${HOME}/Downloads"
sourcecodedir="${HOME}/src"
cd ${sourcecodedir}
mkdir ${mariadbdir}
cd ${mariadbdir}
tar -zxvf ${downloadsdir}/mariadb-shared-repo.tgz
```

1. After the untar step you will have a bzr shared repository, but not a working tree. While in the shared repository directory, use the `bzr branch` command to branch the MariaDB trees you are interested in. For example:

- `bzr branch lp:maria/5.2`
- `bzr branch lp:maria`

1. Thanks to the repository, either of the above commands will complete very fast.
2. Before working with the code, make sure you pull down the latest version of the source code:

```
cd mariadb-5.2 #or to wherever your MariaDB tree is
bzr pull
```

1. You can now use this source tree as if you had branched it from launchpad directly.

Alternate Bazaar Instructions

The following alternative instructions are what we have used for setting up repositories on our build machines in buildbot.

Shell Variables

To streamline later steps, we start by setting several shell variables. Set the values of the BZR and WORK_DIR variables to the appropriate values for your
Linux distribution. The rest of the variables in this section should not need to be changed.

Binaries:

```
BZR="/usr/bin/bzr"
```

Directories

```
WORK_DIR="${HOME}/work/monty_program"

MARIA_DIR=${WORK_DIR}/mariadb
MARIA_REPO="lp:maria"
MARIA_MASTER="${MARIA_DIR}/maria-local-master"
MARIA_WORK="${MARIA_DIR}/maria"

PACKAGING_DIR=${WORK_DIR}/packaging
PACKAGING_REPO="lp:~maria-captains/ourdelta/ourdelta-montyprogram-fixes"
PACKAGING_MASTER="${PACKAGING_DIR}/ourdelta-montyprogram-fixes-local-master"
PACKAGING_WORK="${PACKAGING_DIR}/ourdelta-montyprogram-fixes"
```

Source Checkout

Initialize your bzr working directories, if not done already:

```
$BZR init-repo $MARIA_DIR
$BZR init-repo $PACKAGING_DIR
```

Check out MariaDB sources:

```
$BZR branch $MARIA_REPO $MARIA_MASTER
$BZR branch $MARIA_MASTER $MARIA_WORK
```

Check out packaging sources (only for MariaDB 5.3 and below):

```
$BZR branch $PACKAGING_REPO $PACKAGING_MASTER
$BZR branch $PACKAGING_MASTER $PACKAGING_WORK
```

MariaDB RPM Packages

Packages for Fedora Linux are included with our other packages available for download on .

We have also added YUM repositories to our online Repository Configuration Tool.

This page is licensed: CC BY-SA / Gnu FDL

Mirror Sites for MariaDB

We rely on mirrors to distribute MariaDB to the world through the official download site at download. If you would like to volunteer to become a mirror, thank you! Getting you set up is easy.

> **Tip:**
>
> The state of MariaDB mirrors is monitored at https://mirmon.mariadb.org/

How to Become a MariaDB Mirror

The only requirements for becoming a mirror are: 1. A willingness to mirror MariaDB 1. Mirroring is done using rsync 1. An https mirror should be utilised (http mirrors are not accepted any more) 1. Available bandwidth and disk space

- Each release of MariaDB takes about between 110-140GB of disk space for all of the various packages we create. There are several MariaDB releases per year, but only the most recent two from each main MariaDB series (as of March 2025 this is 10.5, 10.6, 10.11, 11.2, 11.4, 11.7 and 11.8) are kept on the mirrors
- We recommend our mirrors have at least a 100Mbit/sec connection to the Internet

1. The ability to do directory listings on mirrored sub-directories on your mirror host (for some platforms the download page links directly to mirrored sub-directories)
2. The mirror should update itself, preferably every 6 hours, but at the very least, twice a day. (See Updating Notes for more information)
3. Not mandatory: provide `rsync` or `ftp` access to the mirror for our mirrorbits system (See: Mirrorbits)

Updating Notes

MariaDB will normally have no more than one release per series (10.4, 10.5, etc…) per month. There may be times when this is not the case (such as if a major bug is found), but those times are few.

Timing for release announcements is generally oriented to the U.S. Eastern time zone. So if your mirror only updates less frequently than every 6 hours, have it update after midnight, but before 06:00, U.S. Eastern Time.

With rsync, it is no problem to update several times per day, and doing so is encouraged.

rsync Information

The two primary rsync URLs for mirrors to use are:

USA:

```
rsync.osuosl.org::mariadb
```

Europe:

```
mirror.netcologne.de::mariadb
```

Here are suggested rsync commands for a mirror to use:

```
rsync -a --partial --delete-after --delay-updates mirror.netcologne.de::mariadb
/path/to/local/download/directory/rsync_test
```

```
rsync -a --partial --delete-after --delay-updates rsync.osuosl.org::mariadb
/path/to/local/download/directory/rsync_test
```

Be aware that when using the above rsync command, a “mariadb” directory **will not** be created. Instead, the contents of the mariadb module is rsynced into whatever local folder you specify. We suggest creating a “mariadb” folder for this.

It is also a good idea to test your rsync command before adding it to a cron job by adding the `-v --dry-run` flags to the command temporarily so you can see what it will do (without actually doing anything).

As of June 2025, running the above command will use around 750GB of disk space in total.

See the rsync documentation for details on what each of the arguments in the command above does.

Secondary rsync mirrors

We also have several secondary rsync mirrors you can pull from. In many instances pulling from the secondary mirror is faster than pulling from the primary rsync mirrors. Here they are, with the country they are located in. Simply replace the rsync URI in the example above with one from this list to use it.

Country	Rsync URL
Australia	rsync://mirror.aarnet.edu.au/pub/MariaDB/
Bulgaria	rsync://mirrors.neterra.net/MariaDB/
Canada	rsync://mariadb.mirror.globo.tech/mariadb/
China	rsync://mirrors.tuna.tsinghua.edu.cn/mariadb/
Denmark	rsync://mirror.one.com/mariadb/
Estonia	rsync://mirrors.xtom.ee/mariadb/
Germany	rsync://archive.mariadb.org/mariadb/
Germany	rsync://mirror.netcologne.de/mariadb/
Kenya	rsync://mariadb.mirror.liquidtelecom.com/MariaDB/
Morocco	rsync://mirror.marwan.ma/mariadb/
Netherlands	rsync://ftp.nluug.nl/mariadb/
Netherlands	rsync://mirror.nl.mirhosting.net/mariadb/
Norway	rsync://rsync.fjordos.com/mariadb/
Poland	rsync://ftp.icm.edu.pl/pub/unix/database/mariadb/
Portugal	rsync://mirrors.ptisp.pt/mariadb/
Romania	rsync://mirrors.nxthost.com/mariadb/
Russia	rsync://mirror.mephi.ru/mariadb/
Russia	rsync://mirror.truenetwork.ru/MariaDB/
Spain	rsync://mirror.raiolanetworks.com/pub/mariadb/
Taiwan	rsync://ftp.ubuntu-tw.org/mariadb/
Thailand	rsync://mirror.kku.ac.th/mariadb/
United Kingdom	rsync://mariadb.gb.ssimn.org/mariadb/
United States	rsync://mirror.nodesdirect.com/mariadb/
United States	rsync://mirror.us.mirhosting.net/mariadb/
United States	rsync://rsync.osuosl.org/mariadb/
Uruguay	rsync://espejito.fder.edu.uy/mariadb/

The MariaDB Foundation mirrorbits system

The MariaDB Foundation maintains a mirror manager system (see: mirrorbits). It is hosted by Hetzner in Germany, it is **not** available via `rsync` so you can't use it as a source for your mirror but you are encouraged to use it for your MariaDB installation and deployments. You can check the status of the service at https://mirror.mariadb.org/mirrorstats.

Getting Added to the Mirror List

Once you have initially mirrored the MariaDB release tree, please send an email to (mirror (at) mariadb [dot] org) with the following information:

1. The name of the company or organization sponsoring the mirror (so we can give credit where credit is due).
2. Contact name (and email address) for your mirror (so we know who to contact if there are any issues)
3. The general physical location (e.g. "Paris, France", "Hong Kong", or "Austin, Texas, USA") of the mirror (we use geolocation to try and send people to a mirror close to them).
4. The base public URL for the mirror (e.g. `'http://mirror.example.net/pub/mariadb'`).

5. The mirror you are using to rsync from

Once we receive your email and verify your mirror is working we'll add you to the list of mirrors. Apologies in advance in case of slow responses - mirror updates are usually batched around release time.

Thank you for volunteering to mirror MariaDB!

Credits

The primary MariaDB mirrors have been generously provided by the Oregon State University Open Source Lab (at rsync.osuosl.org) and NetCologne (at mirror.netcologne.de).

The MariaDB Archive

The distributed mirrors above only hold the most recent 3-4 releases of each MariaDB series (10.6, 10.11, etc…). If you need to access older MariaDB releases, there is an archive server that contains every MariaDB release. This server is available via the web at archive.mariadb.org and via rsync at:

```
archive.mariadb.org::mariadb
```

Mirroring the MariaDB Archive with rsync

If you want to mirror the archive mirror, please contact us at mirror@mariadb.org in advance.

To mirror the archive with rsync, something like the following will get you everything:

```
rsync -avP archive.mariadb.org::mariadb/ /path/to/local/dir/
```

…or you can specify a specific release such as:

```
rsync -avP archive.mariadb.org::mariadb/mariadb-10.4.13/ /path/to/local/dir/
```

Warning, as of June 2025, the entire archive will use around 14 TB of disk space in total, and if you want to keep your mirror up to date (via cron routine for instance), please **first compare** the STATUS file **before** doing the rsync. This file is updated anytime a new content is added in the archive tree.

You can use something like the following:

```
rsync archive.mariadb.org::mariadb/STATUS /tmp/STATUS
diff -q /tmp/STATUS /path/to/local/dir/STATUS || rsync -avP archive.mariadb.org::mariadb/
/path/to/local/dir/
```

We reserve the right to block IPs that continually rsync the archive mirror when no new content was added, since it uselessly overloads the archive server, which uses a slow remote storage system.

To get a listing of the top level items in the archive including a list of every MariaDB release, just do:

```
rsync archive.mariadb.org::mariadb
```

If you would like to become a full archive mirror of MariaDB and be listed here, just let us know via the contact information above. Thanks!

Where to Download MariaDB

The Latest Packages

Tarballs, binaries (Linux, Solaris, and Windows), and packages for some Linux distributions are available at mariadb.com/downloads/ or mariadb.org/download/ (which also contains a PDF version of the MariaDB Server

documentation).

We hope that interested community package maintainers will step forward, as others already have, to build packages for their distributions. We ask for strict adherence to your packaging system's best practices and invite you to create a bug report if our project impedes this in any way.

Instructions how to install the packages can be found here.

Distributions Which Include MariaDB

- Most distributions already include MariaDB. See Distributions Which Include MariaDB.

Pre-Release Binaries

Binaries from our Buildbot system (see also the Buildbot page), are available at archive. They are not suitable for use in production systems but may be of use for debugging.

Once at the above URL you will need to click on the MariaDB tree you are interested in, and then the build. The build number corresponds to the `tarbuildnum` variable in Buildbot.

For example, if you were interested in the bsd9-64 build of the MariaDB 5.5 tree, revision 3497, the `tarbuildnum` is listed in the "Build Properties" table of the Buildbot build report.
In this case, the value is "2434".

Getting the Source

You can find all the source code at server

To retrieve the code, the Git source control software offers the path of least resistance. If you are unfamiliar with git, please refer to the git documentation for an understanding of version control with git.

For instructions on creating a local branch of MariaDB, see the Getting the MariaDB Source Code page.

See the Generic Build Instructions page for general instructions on compiling MariaDB from the source.
The source page has links to platform and distribution-specific information, including information on how we build the release packages.

Analyzing Tools

See EXPLAIN Analyzer.

The EXPLAIN Analyzer was an online tool for analyzing and sharing EXPLAIN output. It is no longer active.

See EXPLAIN Analyzer API.

The EXPLAIN Analyzer API let applications submit EXPLAIN output to the online analyzer. It is no longer active.

This page is licensed: CC BY-SA / Gnu FDL

EXPLAIN Analyzer

> **Warning:**
>
> The `EXPLAIN` Analyzer is no longer active.

The EXPLAIN Analyzer was an online tool for analyzing and optionally sharing the output of both `EXPLAIN` and `EXPLAIN EXTENDED`.

Using the Analyzer

Using the analyzer is very simple.

In the mariadb client, run `EXPLAIN` on a query and copy the output. For example:

```
EXPLAIN SELECT * FROM t1 INNER JOIN t2 INNER JOIN t3 WHERE t1.a=t2.a AND t2.a=t3.a;
+------+-------------+-------+------+---------------+------+---------+------+------+--------------------
-----------------------------------+
| id   | select_type | table | type | possible_keys | key  | key_len | ref  | rows | Extra
|
+------+-------------+-------+------+---------------+------+---------+------+------+--------------------
-----------------------------------+
|    1 | SIMPLE      | t1    | ALL  | NULL          | NULL | NULL    | NULL |    3 |
|
|    1 | SIMPLE      | t2    | ALL  | NULL          | NULL | NULL    | NULL |    3 | Using where; Using
join buffer (flat, BNL join)        |
|    1 | SIMPLE      | t3    | ALL  | NULL          | NULL | NULL    | NULL |    3 | Using where; Using
join buffer (incremental, BNL join) |
+------+-------------+-------+------+---------------+------+---------+------+------+--------------------
-----------------------------------+
3 rows in set (0.00 sec)
```

1. Paste the output into the EXPLAIN Analyzer input box and click the “Analyze Explain” button.
2. The formatted `EXPLAIN` is shown. You can now click on various part to get more information about them.

Some Notes:

- As you can see in the example above, you don’t need to chop off the query line or the command prompt.
- To save the EXPLAIN, so you can share it, or just for future reference, click the “Save Explain for analysis and sharing” button and then click the “Analyze Explain” button. You is given a link which leads to your saved `EXPLAIN` . For example, the above explain can be viewed here:
- Some of the elements in the formatted `EXPLAIN` are clickable. Clicking on them will show pop-up help related to that element.

Clients which integrate with the Explain Analyzer

The Analyzer has an API that client programs can use to send EXPLAINs. If you are a client application developer, see the EXPLAIN Analyzer API page for details.

The following clients have support for the EXPLAIN Analyzer built in:

HeidiSQL

HeidiSQL has a button when viewing a query that sends the query to the explain analyzer.

CC BY-SA / Gnu FDL

This page is licensed: CC BY-SA / Gnu FDL

EXPLAIN Analyzer API

> **Warning:**
>
> `EXPLAIN` Analyzer is no longer active.

The online `EXPLAIN` Analyzer tool has an open API to allow client applications to send it EXPLAINs.

Sending EXPLAINs to the EXPLAIN Analyzer

To send an `EXPLAIN` to the `EXPLAIN` Analyzer, simply `POST` or `GET` to the following address:

```
mariadb.org/explain_analyzer/api/1/?raw_explain=EXPLAIN&client=CLIENT
```

Replace “EXPLAIN” with the output of the EXPLAIN command and “CLIENT” with the name of your client.

Client Banner

If you like, you can have a banner promoting your client appear at the bottom of the page. Once you’ve added support for the `EXPLAIN` Analyzer to your client application, just send a logo, the name of your client, and what you want the name and logo to link to bryan AT montyprogram DOT com.

HA & Performance

See Optimization and Tuning.

Optimize and tune MariaDB Server. This section covers buffers and caches, indexing, the query optimizer and hints, compression, and the system variables that control performance.

See Replication.

Replicate data with MariaDB Server. This section covers primary and replica setup, binary log formats, global transaction IDs, and multi-source, parallel, and semisynchronous replication.

See Benchmarking.

Benchmark MariaDB Server performance using published benchmark results and SystemTap scripts for measuring throughput and behavior under load.

See MariaDB Memory Allocation.

Plan MariaDB memory usage by sizing global caches, per-connection buffers, and engine-specific settings to avoid swapping and out-of-memory conditions.

See Hardware Optimization.

Optimize MariaDB Server performance through hardware. This section covers selecting appropriate CPU, memory, and storage configurations to maximize your database's speed and throughput.

See Connection Redirection Mechanism in the MariaDB Client/Server Protocol.

Explore connection redirection. This section details how the client/server protocol handles redirection for high availability and load balancing, ensuring seamless database access and failover.

This page is licensed: CC BY-SA / Gnu FDL

Optimization and Tuning

See Buffers, Caches and Threads.

Covers essential configurations to maximize throughput and responsiveness for your database workloads.

See MariaDB Internal Optimizations.

Delves into how the database engine enhances query execution, data storage, and overall performance through its core architecture.

See Operating System Optimizations.

Covers configuring your OS for improved I/O, memory management, and network settings to maximize database efficiency.

See Optimization and Indexes.

Covers index types, creation, and best practices for leveraging them to significantly improve query performance and data retrieval speed.

See Optimizer Hints.

Optimizer hints are options available that affect the execution plan.

See Compression.

Details how to apply data compression at various levels to reduce disk space and improve I/O efficiency.

See Optimizing Data Structure.

Covers schema design, data types, and normalization techniques to improve query efficiency and storage utilization.

See Optimizing Tables.

Covers various techniques, including proper indexing, data types, and storage engine choices, to improve query speed and efficiency.

See Optimizing Queries.

Provides techniques for writing efficient SQL, understanding query execution plans, and leveraging indexes effectively to speed up your queries.

See System and Status Variables.

Optimize MariaDB Server with system variables, configuring various parameters to fine-tune performance, manage resources, and adapt the database to your specific workload requirements.

Buffers, Caches and Threads

See Query Cache.

Complete MariaDB performance optimization guide. Complete reference for query tuning, indexing strategies, and configuration improvements for production use.

See Thread Command Values.

The COMMAND values a thread can show in SHOW PROCESSLIST, and what each one means.

See Thread Pool.

Optimize MariaDB Server with the thread pool. This section explains how to manage connections and improve performance by efficiently handling concurrent client requests, reducing resource overhead.

See Thread States.

Understand MariaDB Server thread states. This section explains the different states a thread can be in, helping you monitor and troubleshoot query execution and server performance.

This page is licensed: CC BY-SA / Gnu FDL

Query Cache

The query cache stores results of `SELECT` queries so that if the identical query is received in future, the results can be quickly returned.

This is extremely useful in high-read, low-write environments (such as most websites). It does not scale well in environments with high throughput on multi-core machines, so it is disabled by default.

Note that the query cache cannot be enabled in certain environments. See Limitations.

Setting Up the Query Cache

Unless MariaDB has been specifically built without the query cache, the query cache will always be available, although inactive. The have_query_cache server variable will show whether the query cache is available.

```
SHOW VARIABLES LIKE 'have_query_cache';
+------------------+-------+
| Variable_name    | Value |
+------------------+-------+
| have_query_cache | YES   |
+------------------+-------+
```

If this is set to `NO`, you cannot enable the query cache unless you rebuild or reinstall a version of MariaDB with the cache available.

To see if the cache is enabled, view the query_cache_type server variable. It is disabled by default — enable it by setting `query_cache_type` to `1` :

```
SET GLOBAL query_cache_type = 1;
```

The query_cache_size is set to 1MB by default. Set the cache to a larger size if needed, for example:

```
SET GLOBAL query_cache_size = 2000000;
```

The `query_cache_type` is automatically set to `ON` if the server is started with the `query_cache_size` set to a non-zero (and non-default) value.

See Limiting the size of the Query Cache below for details.

How the Query Cache Works

When the query cache is enabled and a new `SELECT` query is processed, the query cache is examined to see if the query appears in the cache.

Queries are considered identical if they use the same database, same protocol version and same default character set. Prepared statements are always considered as different to non-prepared statements, see Query cache internal structure for more info.

If the identical query is not found in the cache, the query will be processed normally and then stored, along with its result set, in the query cache. If the query is found in the cache, the results will be pulled from the cache, which is much quicker than processing it normally.

Queries are examined in a case-sensitive manner, so :

```
SELECT * FROM t
```

Is different from :

```
SELECT * from t
```

Comments are also considered and can make the queries differ, so :

```
/* retry */SELECT * FROM t
```

Is different from :

```
/* retry2 */SELECT * FROM t
```

See the query_cache_strip_comments server variable for an option to strip comments before searching.

Each time changes are made to the data in a table, all affected results in the query cache are cleared. It is not possible to retrieve stale data from the query cache.

When the space allocated to query cache is exhausted, the oldest results will be dropped from the cache.

When using `query_cache_type=ON`, and the query specifies `SQL_NO_CACHE` (case-insensitive), the server will not cache the query and will not fetch results from the query cache.

When using `query_cache_type=DEMAND` and the query specifies `SQL_CACHE`, the server will cache the query.

Queries Stored in the Query Cache

If the query_cache_type system variable is set to `1`, or `ON`, all queries fitting the size constraints will be stored in the cache unless they contain a `SQL_NO_CACHE` clause, or are of a nature that caching makes no sense, for example making use of a function that returns the current time. Queries with `SQL_NO_CACHE` will not attempt to acquire query cache lock.

If any of the following functions are present in a query, it will not be cached. Queries with these functions are sometimes called 'non-deterministic' — don't get confused with the use of this term in other contexts.

BENCHMARK()	CONNECTION_ID()
CONVERT_TZ()	CURDATE()
CURRENT_DATE()	CURRENT_TIME()
CURRENT_TIMESTAMP()	CURTIME()
DATABASE()	ENCRYPT() (one parameter)
FOUND_ROWS()	GET_LOCK()
LAST_INSERT_ID()	LOAD_FILE()
MASTER_POS_WAIT()	NOW()
RAND()	RELEASE_LOCK()
SLEEP()	SYSDATE()
UNIX_TIMESTAMP() (no parameters)	USER()
UUID()	UUID_SHORT()

A query will also not be added to the cache if:

- It is of the form:
  - SELECT SQL_NO_CACHE …
  - SELECT … INTO OUTFILE …
  - SELECT … INTO DUMPFILE …
  - SELECT … FOR UPDATE
  - SELECT * FROM … WHERE autoincrement_column IS NULL
  - SELECT … LOCK IN SHARE MODE
- It uses TEMPORARY table
- It uses no tables at all
- It generates a warning
- The user has a column-level privilege on any table in the query
- It accesses a table from INFORMATION_SCHEMA, mysql or the performance_schema database
- It makes use of user or local variables
- It makes use of stored functions
- It makes use of user-defined functions
- It is inside a transaction with the SERIALIZABLE isolation level
- It is querying a table inside a transaction after the same table executed a query cache invalidation using `INSERT`, `UPDATE` or `DELETE`

The query itself can also specify that it is not to be stored in the cache by using the `SQL_NO_CACHE` attribute. Query-level control is an effective way to use the cache more optimally.

It is also possible to specify that *no* queries must be stored in the cache unless the query requires it. To do this, the query_cache_type server variable must be set to `2`, or `DEMAND`. Then, only queries with the `SQL_CACHE` attribute are cached.

Limiting the Size of the Query Cache

There are two main ways to limit the size of the query cache. First, the overall size in bytes is determined by the query_cache_size server variable. About 40KB is needed for various query cache structures.

The query cache size is allocated in 1024 byte-blocks, thus it should be set to a multiple of 1024.

The query result is stored using a minimum block size of query_cache_min_res_unit. Check two conditions to use a good value of this variable: Query cache insert result blocks with locks, each new block insert lock query cache, a small value will increase locks and fragmentation and waste less memory for small results, a big value will increase memory use wasting more memory for small results but it reduce locks. Test with your workload for fine tune this variable.

If the strict mode is enabled, setting the query cache size to an invalid value will cause an error. Otherwise, it will be set to the nearest permitted value, and a warning will be triggered.

```
SHOW VARIABLES LIKE 'query_cache_size';
+------------------+----------+
| Variable_name    | Value    |
+------------------+----------+
| query_cache_size | 67108864 |
+------------------+----------+

SET GLOBAL query_cache_size = 8000000;
Query OK, 0 rows affected, 1 warning (0.03 sec)

SHOW VARIABLES LIKE 'query_cache_size';
+------------------+---------+
| Variable_name    | Value   |
+------------------+---------+
| query_cache_size | 7999488 |
+------------------+---------+
```

The ideal size of the query cache is very dependent on the specific needs of each system. Setting a value too small will result in query results being dropped from the cache when they could potentially be reused later. Setting a value too high could result in reduced performance due to lock contention, as the query cache is locked during updates.

The second way to limit the cache is to have a maximum size for each set of query results. This prevents a single query with a huge result set taking up most of the available memory and knocking a large number of smaller queries out of the cache. This is determined by the query_cache_limit server variable.

If you attempt to set a query cache that is too small (the amount depends on the architecture), the resizing will fail and the query cache will be set to zero, for example :

```
SET GLOBAL query_cache_size=40000;
Query OK, 0 rows affected, 2 warnings (0.03 sec)

SHOW WARNINGS;
+---------+------+-----------------------------------------------------------------+
| Level   | Code | Message                                                         |
+---------+------+-----------------------------------------------------------------+
| Warning | 1292 | Truncated incorrect query_cache_size value: '40000'             |
| Warning | 1282 | Query cache failed to set size 39936; new query cache size is 0 |
+---------+------+-----------------------------------------------------------------+
```

Examining the Query Cache

A number of status variables provide information about the query cache.

```
SHOW STATUS LIKE 'Qcache%';
+-------------------------+----------+
| Variable_name           | Value    |
+-------------------------+----------+
| Qcache_free_blocks      | 1158     |
| Qcache_free_memory      | 3760784  |
| Qcache_hits             | 31943398 |
| Qcache_inserts          | 42998029 |
| Qcache_lowmem_prunes    | 34695322 |
| Qcache_not_cached       | 652482   |
| Qcache_queries_in_cache | 4628     |
| Qcache_total_blocks     | 11123    |
+-------------------------+----------+
```

`Qcache_inserts` contains the number of queries added to the query cache, `Qcache_hits` contains the number of queries that have made use of the query cache, while `Qcache_lowmem_prunes` contains the number of queries that were dropped from the cache due to lack of memory.

The above example could indicate a poorly performing cache. More queries have been added, and more queries have been dropped, than have actually been used.

Results returned by the query cache count towards `Com_select` (see MDEV-4981).

The QUERY_CACHE_INFO plugin creates the QUERY_CACHE_INFO table in the INFORMATION_SCHEMA, allowing you to examine the contents of the query cache.

Query Cache Fragmentation

The Query Cache uses blocks of variable length, and over time may become fragmented. A high `Qcache_free_blocks` relative to `Qcache_total_blocks` may indicate fragmentation. FLUSH QUERY CACHE will defragment the query cache without dropping any queries :

```
FLUSH QUERY CACHE;
```

After this, there will only be one free block :

```
SHOW STATUS LIKE 'Qcache%';
+-------------------------+----------+
| Variable_name           | Value    |
+-------------------------+----------+
| Qcache_free_blocks      | 1        |
| Qcache_free_memory      | 6101576  |
| Qcache_hits             | 31981126 |
| Qcache_inserts          | 43002404 |
| Qcache_lowmem_prunes    | 34696486 |
| Qcache_not_cached       | 655607   |
| Qcache_queries_in_cache | 4197     |
| Qcache_total_blocks     | 8833     |
+-------------------------+----------+
```

Emptying and disabling the Query Cache

To empty or clear all results from the query cache, use RESET QUERY CACHE. FLUSH TABLES will have the same effect.

Setting either query_cache_type or query_cache_size to `0` will disable the query cache, but to free up the most resources, set both to `0` when you wish to disable caching.

Limitations

- The query cache needs to be disabled in order to use OQGRAPH.
- The query cache is not used by the Spider storage engine (amongst others).

LOCK TABLES and the Query Cache

The query cache can be used when tables have a write lock (which may seem confusing since write locks should avoid table reads). This behaviour can be changed by setting the query_cache_wlock_invalidate system variable to `ON`, in which case each write lock will invalidate the table query cache. Setting to `OFF`, the default, means that cached queries can be returned even when a table lock is being held. For example:

```
1> SELECT * FROM T1
+---+
| a |
+---+
| 1 |
+---+
-- Here the query is cached

-- From another connection execute:
2> LOCK TABLES T1 WRITE;

-- Expected result with: query_cache_wlock_invalidate = OFF
1> SELECT * FROM T1
+---+
| a |
+---+
| 1 |
+---+
-- read from query cache

-- Expected result with: query_cache_wlock_invalidate = ON
1> SELECT * FROM T1
-- Waiting Table Write Lock
```

Transactions and the Query Cache

The query cache handles transactions. Internally a flag (`FLAGS_IN_TRANS`) is set to `0` when a query was executed outside a transaction, and to 1 when the query was inside a transaction (begin / COMMIT / ROLLBACK). This flag is part of the “query cache hash”, in others words one query inside a transaction is different from a query outside a transaction.

Queries that change rows (INSERT / UPDATE / DELETE / TRUNCATE) inside a transaction will invalidate all queries from the table, and turn off the query cache to the changed table. Transactions that don’t end with `COMMIT` / `ROLLBACK` check that even without `COMMIT` / `ROLLBACK`, the query cache is turned off to allow row level locking and consistency level.

Examples:

```
SELECT * FROM T1 <first INSERT TO query cache, USING FLAGS_IN_TRANS=0>
+---+
| a |
+---+
| 1 |
+---+
```

```
BEGIN;
SELECT * FROM T1 <first INSERT TO query cache, USING FLAGS_IN_TRANS=1>
+---+
| a |
+---+
| 1 |
+---+
```

```
SELECT * FROM T1 <result FROM query cache, USING FLAGS_IN_TRANS=1>
+---+
| a |
+---+
| 1 |
+---+
```

```
INSERT INTO T1 VALUES(2);  <invalidate queries FROM TABLE T1 AND disable query cache TO TABLE T1>
```

```
SELECT * FROM T1 <don't USE query cache, a normal query FROM innodb TABLE>
+---+
| a |
+---+
| 1 |
| 2 |
+---+
```

```
SELECT * FROM T1 <don't USE query cache, a normal query FROM innodb TABLE>
+---+
| a |
+---+
| 1 |
| 2 |
+---+
```

```
COMMIT;  <query cache IS now turned ON TO T1 TABLE>
```

```
SELECT * FROM T1 <first INSERT TO query cache, USING FLAGS_IN_TRANS=0>
+---+
| a |
+---+
| 1 |
+---+
```

```
SELECT * FROM T1 <result FROM query cache, USING FLAGS_IN_TRANS=0>
+---+
| a |
+---+
| 1 |
+---+
```

Query Cache Internal Structure

Internally, each flag that can change a result using the same query is a different query. For example, using the latin1 charset and using the utf8 charset with the same query are treated as different queries by the query cache.

Some fields that differentiate queries are (from “Query_cache_query_flags” internal structure) :

- query (string)
- current database schema name (string)
- client long flag (0/1)

- client protocol 4.1 (0/1)
- protocol type (internal value)
- more results exists (protocol flag)
- in trans (inside transaction or not)
- autocommit (autocommit session variable)
- pkt_nr (protocol flag)
- character set client (character_set_client session variable)
- character set results (character_set_results session variable)
- collation connection (collation_connection session variable)
- limit (sql_select_limit session variable)
- time zone (time_zone session variable)
- sql_mode (sql_mode session variable)
- max_sort_length (max_sort_length session variable)
- group_concat_max_len (group_concat_max_len session variable)
- default_week_format (default_week_format session variable)
- div_precision_increment (div_precision_increment session variable)
- lc_time_names (lc_time_names session variable)

Timeout and Mutex Contention

When searching for a query inside the query cache, a `try_lock` function waits with a timeout of 50ms. If the lock fails, the query isn't executed via the query cache. This timeout is hard-coded (MDEV-6766 include two variables to tune this timeout).

From the sql_cache.cc, function "try_lock" using `TIMEOUT` :

```
struct timespec waittime;
        set_timespec_nsec(waittime,(ulong)(50000000L));  /* Wait for 50 msec */
        int res= mysql_cond_timedwait(&COND_cache_status_changed,
                                      &structure_guard_mutex, &waittime);
        if (res == ETIMEDOUT)
          break;
```

When inserting a query inside the query cache or aborting a query cache insert (using the KILL command for example), a try_lock function waits until the query cache returns; no timeout is used in this case.

When two processes execute the same query, only the last process stores the query result. All other processes increase the Qcache_not_cached status variable.

SQL_NO_CACHE and SQL_CACHE

There are two aspects to the query cache: placing a query in the cache, and retrieving it from the cache.

1. Adding a query to the query cache. This is done automatically for cacheable queries (see (Queries Stored in the Query Cache) when the query_cache_type system variable is set to `1`, or `ON` and the query contains no `SQL_NO_CACHE` clause, or when the query_cache_type system variable is set to `2`, or `DEMAND`, and the query contains the `SQL_CACHE` clause.
2. Retrieving a query from the cache. This is done after the server receives the query and before the query parser. In this case one point should be considered:

When using `SQL_NO_CACHE`, it should be after the first `SELECT` hint:

```
SELECT SQL_NO_CACHE .... FROM (SELECT SQL_CACHE ...) AS temp_table
```

Don’t use it like this:

```
SELECT SQL_CACHE .... FROM (SELECT SQL_NO_CACHE ...) AS temp_table
```

The second query will be checked. The query cache only checks if `SQL_NO_CACHE` / `SQL_CACHE` exists after the first `SELECT`. (More info at MDEV-6631)

This page is licensed: CC BY-SA / Gnu FDL

Thread Command Values

A thread can have any of the following `COMMAND` values (displayed by the `COMMAND` field listed by the SHOW PROCESSLIST statement or in the Information Schema PROCESSLIST Table, as well as the `PROCESSLIST_COMMAND` value listed in the Performance Schema threads Table). These indicate the nature of the thread’s activity.

Value	Description
Binlog Dump	Master thread for sending binary log contents to a slave.
Change user	Executing a change user operation.
Close stmt	Closing a prepared statement.
Connect	Replication slave is connected to its master.
Connect Out	Replication slave is in the process of connecting to its master.
Create DB	Executing an operation to create a database.
Daemon	Internal server thread rather than for servicing a client connection.
Debug	Generating debug information.
Delayed insert	A delayed-insert handler.
Drop DB	Executing an operation to drop a database.
Error	Error.
Execute	Executing a prepared statement.
Fetch	Fetching the results of an executed prepared statement.
Field List	Retrieving table column information.
Init DB	Selecting default database.
Kill	Killing another thread.
Long Data	Retrieving long data from the result of executing a prepared statement.
Ping	Handling a server ping request.
Prepare	Preparing a prepared statement.
Processlist	Preparing processlist information about server threads.
Query	Executing a statement.
Quit	In the process of terminating the thread.
Refresh	Flushing a table, logs or caches, or refreshing replication server or status variable information.
Register Slave	Registering a slave server.
Reset stmt	Resetting a prepared statement.
Set option	Setting or resetting a client statement execution option.
Sleep	Waiting for the client to send a new statement.
Shutdown	Shutting down the server.

Value	Description
Statistics	Preparing status information about the server.
Table Dump	Sending the contents of a table to a slave.
Time	Not used.

Thread Pool

See Thread Pool in MariaDB.

Explains MariaDB's dynamic, adaptive thread pool: the problems it solves, its features, when it helps or hurts, and how to configure it via thread_handling and related system variables.

See Thread Groups in the Unix Implementation of the Thread Pool.

Describes thread groups in the Unix thread pool implementation, how thread_pool_size sets their number, and how client connections are distributed among them.

See Thread Pool System and Status Variables.

Documents the system and status variables used to configure and monitor the MariaDB thread pool, including extra_max_connections, extra_port, and thread_handling.

See Thread Pool in MariaDB 5.1 - 5.3.

Documents the old pool-of-threads implementation in MariaDB up to version 5.3, retained for reference by older compatibility pages.

Thread Pool in MariaDB

Problems That Thread Pools Solve

The task of scalable server software (and a DBMS like MariaDB is an example of such software) is to maintain top performance with an increasing number of clients. MySQL traditionally assigned a thread for every client connection, and as the number of concurrent users grows this model shows performance drops. Many active threads are a performance killer, because increasing the number of threads leads to extensive context switching, bad locality for CPU caches, and increased contention for hot locks. An ideal solution that would help to reduce context switching is to maintain a lower number of threads than the number of clients. But this number should not be too low either, since we also want to utilize CPUs to their fullest, so ideally, there should be a single active thread for each CPU on the machine.

MariaDB Thread Pool Features

MariaDB has a dynamic and adaptive thread pool, aimed at optimizing resource utilization and preventing deadlocks.

For example, a thread may depend on another thread's completion, and they may block each other via locks and/or I/O. It is hard, and sometimes impossible, to predict how many threads are ideal or even sufficient to prevent deadlocks in every situation. MariaDB implements a dynamic and adaptive pool that takes care of creating new threads in times of high demand, and retiring threads if they have nothing to do. This is a complete reimplementation of the legacy `pool-of-threads` scheduler, with the following goals:

- Make the pool dynamic, so that it will grow and shrink whenever required.
- Minimize the amount of overhead that is required to maintain the thread pool itself.

- Make the best use of underlying OS capabilities. For example, if a native thread pool implementation is available, it should be used. If not, the best I/O multiplexing method should be used.
- Limit the resources used by threads.

There are currently two different low-level implementations – depending on OS. One implementation is designed specifically for Windows which utilizes a native CreateThreadpool API. The second implementation is primarily intended to be used in Unix-like systems. Because the implementations are different, some system variables differ between Windows and Unix.

When to Use the Thread Pool

Thread pools are most efficient in situations where queries are relatively short and the load is CPU-bound, such as in OLTP workloads. If the workload is not CPU-bound, then you might still benefit from limiting the number of threads to save memory for the database memory buffers.

When the Thread Pool is Less Efficient

There are special, rare cases where the thread pool is likely to be less efficient.

- If you have a very bursty workload, then the thread pool may not work well for you. These tend to be workloads in which there are long periods of inactivity followed by short periods of very high activity by many users. These also tend to be workloads in which delays cannot be tolerated, so the throttling of thread creation that the thread pool uses is not ideal. Even in this situation, performance can be improved by tweaking how often threads are retired. For example, with thread_pool_idle_timeout on Unix, or with thread_pool_min_threads on Windows.
- If you have many concurrent, long, non-yielding queries, then the thread pool may not work well for you. In this context, a “non-yielding” query is one that never waits or which does not indicate waits to the thread pool. These kinds of workloads are mostly used in data warehouse scenarios. Long-running, non-yielding queries will delay execution of other queries. However, the thread pool has stall detection to prevent them from totally monopolizing the thread pool. See Thread Groups in the Unix Implementation of the Thread Pool: Thread Group Stalls for more information. Even when the whole thread pool is blocked by non-yielding queries, you can still connect to the server through the extra-port TCP/IP port.
- If you rely on the fact that simple queries always finish quickly, no matter how loaded your database server is, then the thread pool may not work well for you. When the thread pool is enabled on a busy server, even simple queries might be queued to be executed later. This means that even if the statement itself doesn’t take much time to execute, even a simple `SELECT 1`, might take a bit longer when the thread pool is enabled than with `one-thread-per-connection` if it gets queued.

Configuring the Thread Pool

The thread_handling system variable is the primary system variable that is used to configure the thread pool.

There are several other system variables as well, which are described in the sections below. Many of the system variables documented below are dynamic, meaning that they can be changed with SET GLOBAL on a running server.

Generally, there is no need to tweak many of these system variables. The goal of the thread pool was to provide good performance out-of-the box. However, the system variable values can be changed, and we intended to expose as many knobs from the underlying implementation as we could. Feel free to tweak them as you see fit.

If you find any issues with any of the default behavior, then we encourage you to submit a bug report.

See Thread Pool System and Status Variables for the full list of the thread pool’s system variables.

Configuring the Thread Pool on Unix

On Unix, if you would like to use the thread pool, then you can use the thread pool by setting the thread_handling system variable to `pool-of-threads` in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
thread_handling=pool-of-threads
```

The following system variables can also be configured on Unix:

- thread_pool_size – The number of thread groups in the thread pool, which determines how many statements can execute simultaneously. The default value is the number of CPUs on the system. When setting this system variable's value at system startup, the max value is 100000. However, it is not a good idea to set it that high. When setting this system variable's value dynamically, the max value is either 128 or the value that was set at system startup–whichever value is higher. See Thread Groups in the Unix Implementation of the Thread Pool for more information.
- thread_pool_max_threads – The maximum number of threads in the thread pool. Once this limit is reached, no new threads will be created in most cases. In rare cases, the actual number of threads can slightly exceed this, because each thread group needs at least two threads (i.e. at least one worker thread and at least one listener thread) to prevent deadlocks. The default value is `65536`.
- thread_pool_stall_limit – The number of milliseconds between each stall check performed by the timer thread. The default value is `500`. Stall detection is used to prevent a single client connection from monopolizing a thread group. When the timer thread detects that a thread group is stalled, it wakes up a sleeping worker thread in the thread group, if one is available. If there isn't one, then it creates a new worker thread in the thread group. This temporarily allows several client connections in the thread group to run in parallel. However, note that the timer thread will not create a new worker thread if the number of threads in the thread pool is already greater than or equal to the maximum defined by the thread_pool_max_threads variable, unless the thread group does not already have a listener thread. See Thread Groups in the Unix Implementation of the Thread Pool: Thread Group Stalls for more information.
- thread_pool_oversubscribe – Determines how many worker threads in a thread group can remain active at the same time once a thread group is oversubscribed due to stalls. The default value is `3`. Usually, a thread group only has one active worker thread at a time. However, the timer thread can add more active worker threads to a thread group if it detects a stall. There are trade-offs to consider when deciding whether to allow only one thread per CPU to run at a time, or whether to allow more than one thread per CPU to run at a time. Allowing only one thread per CPU means that the thread can have unrestricted access to the CPU while its running, but it also means that there is additional overhead from putting threads to sleep or waking them up more frequently. Allowing more than one thread per CPU means that the threads have to share the CPU, but it also means that there is less overhead from putting threads to sleep or waking them up. This is primarily for internal use, and it is not meant to be changed for most users. See Thread Groups in the Unix Implementation of the Thread Pool: Thread Group Oversubscription for more information.
- thread_pool_idle_timeout – The number of seconds before an idle worker thread exits. The default value is `60`. If there is currently no work to do, how long should an idle thread wait before exiting?

Configuring the Thread Pool on Windows

The Windows implementation of the thread pool uses a native thread pool created with the CreateThreadpool API.

On Windows, if you would like to use the thread pool, then you do not need to do anything, because the default for the thread_handling system variable is already preset to `pool-of-threads`.

However, if you would like to use the old one thread per-connection behavior on Windows, then you can use that by setting the thread_handling system variable to `one-thread-per-connection` in a server option group in an option

file prior to starting up the server. For example:

```
[mariadb]
...
thread_handling=one-thread-per-connection
```

On older versions of Windows, such as XP and 2003, `pool-of-threads` is not implemented, and the server will silently switch to using the legacy `one-thread-per-connection` method.

The native CreateThreadpool API allows applications to set the minimum and maximum number of threads in the pool. The following system variables can be used to configure those values on Windows:

- thread_pool_min_threads – The minimum number of threads in the pool. Default is 1. This applicable in a special case of very "bursty" workloads. Imagine having longer periods of inactivity after periods of high activity. While the thread pool is idle, Windows would decide to retire pool threads (based on experimentation, this seems to happen after thread had been idle for 1 minute). Next time high load comes, it could take some milliseconds or seconds until the thread pool size stabilizes again to optimal value. To avoid thread retirement, one could set the parameter to a higher value.
- thread_pool_max_threads – The maximum number of threads in the pool. Threads are not created when this value is reached. The default is 1000. This parameter can be used to prevent the creation of new threads if the pool can have short periods where many or all clients are blocked (for example, with `FLUSH TABLES WITH READ LOCK`, high contention on row locks, or similar). New threads are created if a blocking situation occurs (such as after a throttling interval), but sometimes you want to cap the number of threads, if you're familiar with the application and need to, for example, save memory. If your application constantly pegs at 500 threads, it might be a strong indicator for high contention in the application, and the thread pool does not help much.

Configuring Priority Scheduling

It is possible to configure connection prioritization. The priority behavior is configured by the thread_pool_priority system variable.

By default, if thread_pool_priority is set to `auto`, then queries would be given a higher priority, in case the current connection is inside a transaction. This allows the running transaction to finish faster, and has the effect of lowering the number of transactions running in parallel. The default setting will generally improve throughput for transactional workloads. But it is also possible to explicitly set the priority for the current connection to either 'high' or 'low'.

There is also a mechanism in place to ensure that higher priority connections are not monopolizing the worker threads in the pool (which would cause indefinite delays for low priority connections). On Unix, low priority connections are put into the high priority queue after the timeout specified by the thread_pool_prio_kickup_timer system variable.

Configuring the Extra Port

MariaDB allows you to configure an extra port for administrative connections. This is primarily intended to be used in situations where all threads in the thread pool are blocked, and you still need a way to access the server. However, it can also be used to ensure that monitoring systems (including MaxScale's monitors) always have access to the system, even when all connections on the main port are used. This extra port uses the old `one-thread-per-connection` thread handling.

You can enable this and configure a specific port by setting the extra_port system variable.

You can configure a specific number of connections for this port by setting the extra_max_connections system variable.

These system variables can be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
extra_port = 8385
extra_max_connections = 10
```

Once you have the extra port configured, you can use the mariadb client with the `-P` option to connect to the port.

```
$ mariadb -u root -P 8385 -p
```

Monitoring Thread Pool Activity

Currently there are two status variables exposed to monitor pool activity.

Variable	Description
Threadpool_threads	Number of threads in the thread pool. In rare cases, this can be slightly higher than thread_pool_max_threads, because each thread group needs at least two threads (i.e. at least one worker thread and at least one listener thread) to prevent deadlocks.
Threadpool_idle_threads	Number of inactive threads in the thread pool. Threads become inactive for various reasons, such as by waiting for new work. However, an inactive thread is not necessarily one that has not been assigned work. Threads are also considered inactive if they are being blocked while waiting on disk I/O, or while waiting on a lock, etc. This status variable is only meaningful on Unix.

Thread Groups in the Unix Implementation of the Thread Pool

On Unix, the thread pool implementation uses objects called thread groups to divide up client connections into many independent sets of threads. See Thread Groups in the Unix Implementation of the Thread Pool for more information.

Fixing a Blocked Thread Pool

When using global locks, even with a high value on the thread_pool_max_threads system variable, it is still possible to block the entire pool.

Imagine the case where a client performs FLUSH TABLES WITH READ LOCK then pauses. If then the number of other clients connecting to the server to start write operations exceeds the maximum number of threads allowed in the pool, it can block the Server. This makes it impossible to issue the UNLOCK TABLES statement. It can also block MaxScale from monitoring the Server.

To mitigate the issue, MariaDB allows you to configure an extra port for administrative connections. See Configuring the Extra Port for information on how to configure this.

Once you have the extra port configured, you can use the mariadb client with the `-P` option to connect to the port.

```
$ mariadb -u root -P 8385 -p
```

This ensures that your administrators can access the server in cases where the number of threads is already equal to the configured value of the thread_pool_max_threads system variable, and all threads are blocked. It also ensures that MaxScale can still access the server in such situations for monitoring information.

Once you are connected to the extra port, you can solve the issue by increasing the value on the thread_pool_max_threads system variable, or by killing the offending connection, (that is, the connection that holds the global lock, which would be in the `sleep` state).

Information Schema

The following Information Schema tables relate to the thread pool:

- Information Schema THREAD_POOL_GROUPS Table
- Information Schema THREAD_POOL_QUEUES Table

- Information Schema THREAD_POOL_STATS Table
- Information Schema THREAD_POOL_WAITS Table

MariaDB Thread Pool vs Oracle MySQL Enterprise Thread Pool

Commercial editions of MySQL since 5.5 include an Oracle MySQL Enterprise thread pool implemented as a plugin, which delivers similar functionality. A detailed discussion about the design of the feature is at Mikael Ronstrom's blog. Here is the summary of similarities and differences, based on the above materials.

Similarities

- On Unix, both MariaDB and Oracle MySQL Enterprise Thread Pool will partition client connections into groups. The thread_pool_size parameter thus has the same meaning for both MySQL and MariaDB.
- Both implementations use similar schema checking for thread stalls, and both have the same parameter name for thread_pool_stall_limit (though in MariaDB it is measured using millisecond units, not 10ms units like in Oracle MySQL).

Differences

- The Windows implementation is completely different – MariaDB's uses native Windows thread pooling, while Oracle's implementation includes a convenience function WSAPoll() (provided for convenience to port Unix applications). As a consequence of relying on WSAPoll(), Oracle's implementation does not work with named pipes and shared memory connections.
- MariaDB uses the most efficient I/O multiplexing facilities for each operating system: Windows (the I/O completion port is used internally by the native thread pool), Linux (epoll), Solaris (event ports), FreeBSD and OSX (kevent). Oracle uses optimized I/O multiplexing only on Linux, with epoll, and uses poll() otherwise.
- Unlike Oracle MySQL Enterprise Thread Pool, MariaDB's one is built in, not a plugin.

MariaDB Thread Pool vs Percona Thread Pool

Percona's implementation is a port of the MariaDB's thread pool with some added features. In particular, Percona added priority scheduling to its 5.5-5.7 releases. MariaDB and Percona priority scheduling works in a similar fashion, but there are some differences in details.

- MariaDB's `thread_pool_priority=auto,high, low` correspond to Percona's `thread_pool_high_prio_mode=transactions,statements,none`.
- Percona has a `thread_pool_high_prio_tickets` connection variable to allow every nth low priority query to be put into the high priority queue. MariaDB does not have a corresponding setting.
- MariaDB has a `thread_pool_prio_kickup_timer` setting, which Percona does not have.

Running Benchmarks

When running `sysbench` and maybe other benchmarks, that create many threads on the same machine as the server, it is advisable to run benchmark driver and server on different CPUs to get the realistic results. Running lots of driver threads and only several server threads on the same CPUs will have the effect that OS scheduler will schedule benchmark driver threads to run with much higher probability than the server threads, that is driver will preempt the server. Use "taskset –c" on Linuxes, and "set /affinity" on Windows to separate benchmark driver and server CPUs, as the preferred method to fix this situation.

A possible alternative on Unix (if taskset or a separate machine running the benchmark is not desired for some reason) would be to increase thread_pool_size to make the server threads more "competitive" against the client threads.

When running sysbench, a good rule of thumb could be to give 1/4 of all CPUs to the sysbench, and 3/4 of CPUs to mariadbd. It is also good idea to run sysbench and mariadbd on different NUMA nodes, if possible.

Notes

The thread_cache_size system variable is not used when the thread pool is used and the Threads_cached status variable will have a value of 0.

Thread Groups in the Unix Implementation of the Thread Pool

This article does not apply to the thread pool implementation on Windows. On Windows, MariaDB uses a native thread pool created with the CreateThreadpool API, which has its own methods to distribute threads between CPUs.

On Unix, the thread pool implementation uses objects called thread groups to divide up client connections into many independent sets of threads. The thread_pool_size system variable defines the number of thread groups on a system. Generally speaking, the goal of the thread group implementation is to have one running thread on each CPU on the system at a time. Therefore, the default value of the thread_pool_size system variable is auto-sized to the number of CPUs on the system.

When setting the thread_pool_size system variable's value at system startup, the max value is `100000`. However, it is not a good idea to set it that high. When setting its value dynamically, the max value is either `128` or the value that was set at system startup–whichever value is higher. It can be changed dynamically with SET GLOBAL. For example:

```
SET GLOBAL thread_pool_size=32;
```

It can also be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
..
thread_handling=pool-of-threads
thread_pool_size=32
```

If you do not want MariaDB to use all CPUs on the system for some reason, then you can set it to a lower value than the number of CPUs. For example, this would make sense if the MariaDB Server process is limited to certain CPUs with the taskset utility on Linux.

If you set the value to the number of CPUs and if you find that the CPUs are still underutilized, then try increasing the value.

The thread_pool_size system variable tends to have the most visible performance effect. It is roughly equivalent to the number of threads that can run at the same time. In this case, run means use CPU, rather than sleep or wait. If a client connection needs to sleep or wait for some reason, then it wakes up another client connection in the thread group before it does so.

One reason that CPU underutilization may occur in rare cases is that the thread pool is not always informed when a thread is going to wait. For example, some waits, such as a page fault or a miss in the OS buffer cache, cannot be detected by MariaDB.

Distributing Client Connections Between Thread Groups

When a new client connection is created, its thread group is determined using the following calculation:

```
thread_group_id = connection_id % thread_pool_size
```

The `connection_id` value in the above calculation is the same monotonically increasing number that you can use to identify connections in SHOW PROCESSLIST output or the information_schema.PROCESSLIST table.

This calculation should assign client connections to each thread group in a round-robin manner. In general, this should result in an even distribution of client connections among thread groups.

Types of Threads

Thread Group Threads

Thread groups have two different kinds of threads: a **listener thread** and **worker threads**.

- A thread group's worker threads actually perform work on behalf of client connections. A thread group can have many worker threads, but usually, only one will be actively running at a time. This is not always the case. For example, the thread group can become oversubscribed if the thread pool's timer thread detects that the thread group is stalled. This is explained more in the sections below.
- A thread group's listener thread listens for I/O events and distributes work to the worker threads. If it detects that there is a request that needs to be worked on, then it can wake up a sleeping worker thread in the thread group, if any exist. If the listener thread is the only thread in the thread group, then it can also create a new worker thread. If there is only one request to handle, and if the thread_pool_dedicated_listener system variable is not enabled, then the listener thread can also become a worker thread and handle the request itself. This helps decrease the overhead that may be introduced by excessively waking up sleeping worker threads and excessively creating new worker threads.

Global Threads

The thread pool has one global thread: a **timer thread**. The **timer thread** performs tasks, such as:

- Checks each thread group for stalls.
- Ensures that each thread group has a listener thread.

Thread Creation

A new thread is created in a thread group in the scenarios listed below.

In all of the scenarios below, the thread pool implementation prefers to wake up a sleeping **worker thread** that already exists in the thread group, rather than to create a new thread.

Worker Thread Creation by Listener Thread

A thread group's **listener thread** can create a new **worker thread** when it has more client connection requests to distribute, but no pre-existing **worker threads** are available to work on the requests. This can help to ensure that the thread group always has enough threads to keep one **worker thread** active at a time.

A thread group's **listener thread** creates a new **worker thread** if all of the following conditions are met:

- The listener thread receives a client connection request that needs to be worked on.
- There are more client connection requests in the thread group's work queue that the listener thread still needs to distribute to worker threads, so the listener thread should not become a worker thread.
- There are no active worker threads in the thread group.
- There are no sleeping worker threads in the thread group that the listener thread can wake up.
- And one of the following conditions is also met:
  - The entire thread pool has fewer than thread_pool_max_threads.
  - There are fewer than two threads in the thread group. This is to guarantee that each thread group can have at least two threads, even if thread_pool_max_threads has already been reached or exceeded.

Thread Creation by Worker Threads During Waits

A thread group's **worker thread** can create a new **worker thread** when the thread has to wait on something, and the thread group has more client connection requests queued, but no pre-existing **worker threads** are available to work on them. This can help to ensure that the thread group always has enough threads to keep one **worker thread** active at a time. For most workloads, this tends to be the primary mechanism that creates new **worker threads**.

A thread group's **worker thread** creates a new thread if all of the following conditions are met:

- The worker thread has to wait on some request. For example, it might be waiting on disk I/O, or it might be waiting on a lock, or it might just be waiting for a query that called the SLEEP() function to finish.
- There are no active worker threads in the thread group.
- There are no sleeping worker threads in the thread group that the worker thread can wake up.
- And one of the following conditions is also met:
  - The entire thread pool has fewer than thread_pool_max_threads.
  - There are fewer than two threads in the thread group. This is to guarantee that each thread group can have at least two threads, even if thread_pool_max_threads has already been reached or exceeded.
- And one of the following conditions is also met:
  - There are more client connection requests in the thread group's work queue that the listener thread still needs to distribute to worker threads. In this case, the new thread is intended to be a worker thread.
  - There is currently no listener thread in the thread group. For example, if the thread_pool_dedicated_listener system variable is not enabled, then the thread group's listener thread can became a worker thread, so that it could handle some client connection request. In this case, the new thread can become the thread group's listener thread.

Listener Thread Creation by Timer Thread

The thread pool's **timer thread** can create a new **listener thread** for a thread group when the thread group has more client connection requests that need to be distributed, but the thread group does not currently have a **listener thread** to distribute them. This can help to ensure that the thread group does not miss client connection requests because it has no **listener thread**.

The thread pool's **timer thread** creates a new **listener thread** for a thread group if all of the following conditions are met:

- The thread group has not handled any I/O events since the last check by the timer thread.
- There is currently no listener thread in the thread group. For example, if the thread_pool_dedicated_listener system variable is not enabled, then the thread group's listener thread can became a worker thread, so that it could handle some client connection request. In this case, the new thread can become the thread group's listener thread.
- There are no sleeping worker threads in the thread group that the timer thread can wake up.
- And one of the following conditions is also met:
  - The entire thread pool has fewer than thread_pool_max_threads.
  - There are fewer than two threads in the thread group. This is to guarantee that each thread group can have at least two threads, even if thread_pool_max_threads has already been reached or exceeded.
- If the thread group already has active worker threads, then the following condition also needs to be met:
  - A worker thread has not been created for the thread group within the throttling interval.

Worker Thread Creation by Timer Thread during Stalls

The thread pool's **timer thread** can create a new **worker thread** for a thread group when the thread group is stalled. This can help to ensure that a long query can't monopole its thread group.

The thread pool's **timer thread** creates a new **worker thread** for a thread group if all of the following conditions are met:

- The timer thread thinks that the thread group is stalled. This means that the following conditions have been met:
  - There are more client connection requests in the thread group's work queue that the listener thread still needs to distribute to worker threads.
  - No client connection requests have been allowed to be dequeued to run since the last stall check by the timer thread.
- There are no sleeping worker threads in the thread group that the timer thread can wake up.
- And one of the following conditions is also met:
  - The entire thread pool has fewer than thread_pool_max_threads.
  - There are fewer than two threads in the thread group. This is to guarantee that each thread group can have at least two threads, even if thread_pool_max_threads has already been reached or exceeded.
- A worker thread has not been created for the thread group within the throttling interval.

Thread Creation Throttling

In some of the scenarios listed above, a thread is only created within a thread group if no new threads have been created for the thread group within the *throttling interval*. The throttling interval depends on the number of threads that are already in the thread group.

In MariaDB 10.5 and later, thread creation is not throttled until a thread group has more than 1 + thread_pool_oversubscribe threads:

Number of Threads in Thread Group	Throttling Interval (milliseconds)
0-(1 + thread_pool_oversubscribe)	0
4-7	50 * `THROTTLING_FACTOR`
8-15	100 * `THROTTLING_FACTOR`
16-65536	20 * `THROTTLING_FACTOR`

The throttling factor is calculated like this (see thread_pool_stall_limit for more information):

```
THROTTLING_FACTOR = thread_pool_stall_limit / MAX (500,thread_pool_stall_limit)
```

Thread Group Stalls

The thread pool has a feature that allows it to detect if a client connection is executing a long-running query that may be monopolizing its thread group. If a client connection were to monopolize its thread group, then that could prevent other client connections in the thread group from running their queries. In other words, the thread group would appear to be *stalled*.

This stall detection feature is implemented by creating a **timer thread** that periodically checks if any of the thread groups are stalled. There is only a single **timer thread** for the entire thread pool. The thread_pool_stall_limit system variable defines the number of milliseconds between each stall check performed by the timer thread. The default value is `500`. It can be changed dynamically with SET GLOBAL. For example:

```
SET GLOBAL thread_pool_stall_limit=300;
```

It can also be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
..
thread_handling=pool-of-threads
thread_pool_size=32
thread_pool_stall_limit=300
```

The **timer thread** considers a thread group to be stalled if the following is true:

- There are more client connection requests in the thread group's work queue that the listener thread still needs to distribute to worker threads.
- No client connection requests have been allowed to be dequeued to run since the last stall check by the timer thread.

This indicates that the one or more client connections currently using the active **worker threads** may be monopolizing the thread group, and preventing the queued client connections from performing work. When the **timer thread** detects that a thread group is stalled, it wakes up a sleeping **worker thread** in the thread group, if one is available. If there isn't one, then it creates a new **worker thread** in the thread group. This temporarily allows several client connections in the thread group to run in parallel.

The thread_pool_stall_limit system variable essentially defines the limit for what a "fast query" is. If a query takes longer than thread_pool_stall_limit, then the thread pool is likely to think that it is too slow, and it will either wake up a sleeping worker thread or create a new worker thread to let another client connection in the thread group run a query in parallel.

In general, changing the value of the thread_pool_stall_limit system variable has the following effect:

- Setting it to higher values can help avoid starting too many parallel threads if you expect a lot of client connections to execute long-running queries.
- Setting it to lower values can help prevent deadlocks.

Thread Group Oversubscription

If the **timer thread** were to detect a stall in a thread group, then it would either wake up a sleeping **worker thread** or create a new **worker thread** in that thread group. At that point, the thread group would have multiple active **worker threads**. In other words, the thread group would be *oversubscribed*.

You might expect that the thread pool would shutdown one of the **worker threads** when the stalled client connection finished what it was doing, so that the thread group would only have one active **worker thread** again. However, this does not always happen. Once a thread group is oversubscribed, the thread_pool_oversubscribe system variable defines the upper limit for when **worker threads** start shutting down after they finish work for client connections. The default value is `3`. It can be changed dynamically with SET GLOBAL. For example:

```
SET GLOBAL thread_pool_oversubscribe=10;
```

It can also be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
..
thread_handling=pool-of-threads
thread_pool_size=32
thread_pool_stall_limit=300
thread_pool_oversubscribe=10
```

To clarify, the thread_pool_oversubscribe system variable does not play any part in the creation of new **worker threads**. The thread_pool_oversubscribe system variable is only used to determine how many **worker threads** should remain active in a thread group, once a thread group is already oversubscribed due to stalls.

In general, the default value of `3` should be adequate for most users. Most users should not need to change the value of the thread_pool_oversubscribe system variable.

Thread Pool System and Status Variables

This article describes the system and status variables used by the MariaDB thread pool. For a full description, see Thread Pool in MariaDB.

System variables

`extra_max_connections`

- Description: The number of connections on the extra_port.
  - See Thread Pool in MariaDB: Configuring the Extra Port for more information.
- Command line: `--extra-max-connections=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `1`
- Range: `1` to `100000`

`extra_port`

- Description: Extra port number to use for TCP connections in a `one-thread-per-connection` manner. If set to `0`, then no extra port is used.
  - See Thread Pool in MariaDB: Configuring the Extra Port for more information.
- Command line: `--extra-port=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `0`

`thread_handling`

- Description: Determines how the server handles threads for client connections. In addition to threads for client connections, this also applies to certain internal server threads, such as Galera slave threads. On Windows, if you would like to use the thread pool, then you do not need to do anything, because the default for the thread_handling system variable is already preset to `pool-of-threads`.
  - When the default `one-thread-per-connection` mode is enabled, the server uses one thread to handle each client connection.
  - When the `pool-of-threads` mode is enabled, the server uses the thread pool for client connections.
  - When the `no-threads` mode is enabled, the server uses a single thread for all client connections, which is really only usable for debugging.
- Command line: `--thread-handling=name`
- Scope: Global
- Dynamic: No
- Data Type: `enumeration`
- Default Value: `one-thread-per-connection` (non-Windows), `pool-of-threads` (Windows)

- Valid Values: `no-threads`, `one-thread-per-connection`, `pool-of-threads`.
- Documentation: Using the thread pool.
- Notes: In MySQL, the thread pool is only available in MySQL Enterprise. In MariaDB it's available in all versions.

`thread_pool_dedicated_listener`

- Description: If set to 1, then each group will have its own dedicated listener, and the listener thread will not pick up work items. As a result, the queueing time in the Information Schema Threadpool_Queues and the actual queue size in the Information Schema Threadpool_Groups table will be more exact, since IO requests are immediately dequeued from poll, without delay.
  - This system variable is only meaningful on Unix.
- Command line: `thread-pool-dedicated-listener={0|1}`
- Scope:
- Dynamic:
- Data Type: `boolean`
- Default Value: `0`
- Introduced: MariaDB 10.5.0

`thread_pool_exact_stats`

- Description: If set to 1, provides better queueing time statistics by using a high precision timestamp, at a small performance cost, for the time when the connection was added to the queue. This timestamp helps calculate the queuing time shown in the Information Schema Threadpool_Queues table.
  - This system variable is only meaningful on Unix.
- Command line: `thread-pool-exact-stats={0|1}`
- Scope:
- Dynamic:
- Data Type: `boolean`
- Default Value: `0`
- Introduced: MariaDB 10.5.0

`thread_pool_idle_timeout`

- Description: The number of seconds before an idle worker thread exits. The default value is `60`. If there is currently no work to do, how long should an idle thread wait before exiting?
  - This system variable is only meaningful on Unix.
  - The thread_pool_min_threads system variable is comparable for Windows.
- Command line: `thread-pool-idle-timeout=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `60`
- Documentation: Using the thread pool.

`thread_pool_max_threads`

- Description: The maximum number of threads in the thread pool. Once this limit is reached, no new threads will be created in most cases.

    - On Unix, in rare cases, the actual number of threads can slightly exceed this, because each thread group needs at least two threads (i.e. at least one worker thread and at least one listener thread) to prevent deadlocks.

- Scope:
- Command line: `thread-pool-max-threads=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `65536`
- Range: `1` to `65536`
- Documentation: Using the thread pool.

`thread_pool_min_threads`

- Description: Minimum number of threads in the thread pool. In bursty environments, after a period of inactivity, threads would normally be retired. When the next burst arrives, it would take time to reach the optimal level. Setting this value higher than the default would prevent thread retirement even if inactive.
    - This system variable is only meaningful on Windows.
    - The thread_pool_idle_timeout system variable is comparable for Unix.
- Command line: `thread-pool-min-threads=#`
- Data Type: `numeric`
- Default Value: `1`
- Documentation: Using the thread pool.

`thread_pool_oversubscribe`

- Description: Determines how many worker threads in a thread group can remain active at the same time once a thread group is oversubscribed due to stalls. The default value is `3`. Usually, a thread group only has one active worker thread at a time. However, the timer thread can add more active worker threads to a thread group if it detects a stall. There are trade-offs to consider when deciding whether to allow only one thread per CPU to run at a time, or whether to allow more than one thread per CPU to run at a time. Allowing only one thread per CPU means that the thread can have unrestricted access to the CPU while its running, but it also means that there is additional overhead from putting threads to sleep or waking them up more frequently. Allowing more than one thread per CPU means that the threads have to share the CPU, but it also means that there is less overhead from putting threads to sleep or waking them up.
    - See Thread Groups in the Unix Implementation of the Thread Pool: Thread Group Oversubscription for more information.
    - This is primarily for internal use, and it is not meant to be changed for most users.
    - This system variable is only meaningful on Unix.
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `3`
- Range: `1` to `65536`
- Documentation: Using the thread pool.

`thread_pool_prio_kickup_timer`

- Description: Time in milliseconds before a dequeued low-priority statement is moved to the high-priority queue.

    - This system variable is only meaningful on Unix.
- Command line: `thread-pool-kickup-timer=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `1000`
- Range: `0` to `4294967295`
- Introduced: MariaDB 10.2.2
- Documentation: Using the thread pool.

`thread_pool_priority`

- Description: Thread pool priority. High-priority connections usually start executing earlier than low-priority. If set to 'auto' (the default), the actual priority (low or high) is determined by whether or not the connection is inside a transaction.
- Command line: `--thread-pool-priority=#`
- Scope: Global,Connection
- Data Type: `enum`
- Default Value: `auto`
- Valid Values: `high`, `low`, `auto`.
- Introduced: MariaDB 10.2.2
- Documentation: Using the thread pool.

`thread_pool_size`

- Description: The number of thread groups in the thread pool, which determines how many statements can execute simultaneously. The default value is the number of CPUs on the system. When setting this system variable's value at system startup, the max value is 100000. However, it is not a good idea to set it that high. When setting this system variable's value dynamically, the max value is either 128 or the value that was set at system startup–whichever value is higher.
    - See Thread Groups in the Unix Implementation of the Thread Pool for more information.
    - This system variable is only meaningful on Unix.
- Command line: `--thread-pool-size=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: Based on the number of processors (but see MDEV-7806).
- Range: `1` to `128`
- Documentation: Using the thread pool.

`thread_pool_stall_limit`

- Description: The number of milliseconds between each stall check performed by the timer thread. The default value is `500`. Stall detection is used to prevent a single client connection from monopolizing a thread group. When the timer thread detects that a thread group is stalled, it wakes up a sleeping worker thread in the thread group, if one is available. If there isn't one, then it creates a new worker thread in the thread group. This temporarily allows several client connections in the thread group to run in parallel. However, note that the timer thread will not create a new worker thread if the number of threads in the thread pool is already greater than or

equal to the maximum defined by the thread_pool_max_threads variable, unless the thread group does not already have a listener thread.
    - See Thread Groups in the Unix Implementation of the Thread Pool: Thread Group Stalls for more information.
    - This system variable is only meaningful on Unix.
    - Note that if you are migrating from the MySQL Enterprise thread pool plugin, then the unit used in their implementation is 10ms, not 1ms.

- Command line: `--thread-pool-stall-limit=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `500`
- Range: `1` to `4294967295`
- Documentation: Using the thread pool.

Status variables

`Threadpool_idle_threads`

- Description: Number of inactive threads in the thread pool. Threads become inactive for various reasons, such as by waiting for new work. However, an inactive thread is not necessarily one that has not been assigned work. Threads are also considered inactive if they are being blocked while waiting on disk I/O, or while waiting on a lock, etc.
    - This status variable is only meaningful on Unix.
- Scope: Global, Session
- Data Type: `numeric`

`Threadpool_threads`

- Description: Number of threads in the thread pool. In rare cases, this can be slightly higher than thread_pool_max_threads, because each thread group needs at least two threads (i.e. at least one worker thread and at least one listener thread) to prevent deadlocks.
- Scope: Global, Session
- Data Type: `numeric`

Thread Pool in MariaDB 5.1 - 5.3

> **Note:**
>
> This page describes the old thread pool implementation in MariaDB up to version 5.3.
>
> It's left here because some compatibility pages in the release notes refer to it.
>
> For the current implementation, refer to the Thread Pool in MariaDB page.

About Pool of Threads

This is an extended version of the pool-of-threads code from MySQL 6.0. This allows you to use a limited set of threads to handle all queries, instead of the old 'one-thread-per-connection' style. In recent times, its also been referred to as "thread pool" or "thread pooling" as this feature (in a different implementation) is available in Enterprise editions of MySQL (not in the Community edition).

This can be a very big win if most of your queries are short running queries and there are few table/row locks in your system.

Instructions

To enable pool-of-threads you must first run configure with the `--with-libevent` option. (This is automatically done if you use any 'max' scripts in the BUILD directory):

```
./configure --with-libevent
```

When starting mysqld with the pool of threads code you should use:

```
mysqld --thread-handling=pool-of-threads --thread-pool-size=20
```

Default values are:

```
thread-handling=  one-thread-per-connection
thread-pool-size= 20
```

One issue with pool-of-threads is that if all worker threads are doing work (like running long queries) or are locked by a row/table lock no new connections can be established and you can't login and find out what's wrong or login and kill queries.

To help this, we have introduced two new options for mysqld; extra_port and extra_max_connections:

```
--extra-port=#             (Default 0)
--extra-max-connections=#  (Default 1)
```

If extra-port is <> 0 then you can connect max_connections number of normal threads + 1 extra SUPER user through the 'extra-port' TCP/IP port. These connections use the old one-thread-per-connection method.

To connect with through the extra port, use:

```
mysql --port='number-of-extra-port' --protocol=tcp
```

This allows you to freely use, on connection bases, the optimal connection/thread model.

Thread States

See Delayed Insert Connection Thread States.

Lists the thread states for the connection thread that processes INSERT DELAYED statements, as shown by SHOW PROCESSLIST and related tables.

See Delayed Insert Handler Thread States.

Lists the thread states for the handler thread that inserts the results of INSERT DELAYED statements, as shown by SHOW PROCESSLIST and related tables.

See Event Scheduler Thread States.

Lists the thread states related to event scheduling and execution, as shown by SHOW PROCESSLIST and related tables.

See Galera Cluster Thread States.

Lists the Galera Cluster-specific thread states shown in SHOW PROCESSLIST during cluster operations, such as certification, flow control, and Total Order Isolation DDL waits.

See General Thread States.

Documents the major general thread states shown by SHOW PROCESSLIST and related tables, with links to the more specific state lists for replication, the query cache, and other subsystems.

See Master Thread States.

Lists the thread states related to replication primary (master) threads, as shown by SHOW PROCESSLIST and related tables.

See Query Cache Thread States.

Lists the thread states related to the query cache, as shown by SHOW PROCESSLIST and related tables.

See Replica I/O Thread States.

Lists the replica I/O thread states shown by Slave_IO_State in SHOW REPLICA STATUS and by SHOW PROCESSLIST and related tables.

See Replica Connection Thread States.

Lists the thread states for connection threads on a replication replica, as shown by SHOW PROCESSLIST and related tables.

See Replica SQL Thread States.

Lists the replica SQL thread states shown by Slave_SQL_State in SHOW REPLICA STATUS and by SHOW PROCESSLIST and related tables, including parallel replication states.

This page is licensed: CC BY-SA / Gnu FDL

Delayed Insert Connection Thread States

This article documents thread states that are related to the connection thread that processes INSERT DELAYED statements.

These correspond to the `STATE` values listed by the SHOW PROCESSLIST statement or in the Information Schema PROCESSLIST Table as well as the `PROCESSLIST_STATE` value listed in the Performance Schema threads Table.

Value	Description
allocating local table	Preparing to allocate rows to the delayed-insert handler thread. Follows from the got handler lock state.
Creating delayed handler	Creating a handler for the delayed-inserts.
got handler lock	Lock to access the delayed-insert handler thread has been received. Follows from the waiting for handler lock state and before the allocating local table state.
got old table	The initialization phase is over. Follows from the waiting for handler open state.

Value	Description
storing row into queue	Adding new row to the list of rows to be inserted by the delayed-insert handler thread.
waiting for delay_list	Initializing (trying to find the delayed-insert handler thread).
waiting for handler insert	Waiting for new inserts, as all inserts have been processed.
waiting for handler lock	Waiting for delayed insert-handler lock to access the delayed-insert handler thread.
waiting for handler open	Waiting for the delayed-insert handler thread to initialize. Follows from the Creating delayed handler state and before the got old table state.

This page is licensed: CC BY-SA / Gnu FDL

Delayed Insert Handler Thread States

This article documents thread states that are related to the handler thread that inserts the results of INSERT DELAYED statements.

These correspond to the `STATE` values listed by the SHOW PROCESSLIST statement or in the Information Schema PROCESSLIST Table as well as the `PROCESSLIST_STATE` value listed in the Performance Schema threads Table.

Value	Description
insert	About to insert rows into the table.
reschedule	Sleeping in order to let other threads function, after inserting a number of rows into the table.
upgrading lock	Attempting to get lock on the table in order to insert rows.
Waiting for INSERT	Waiting for the delayed-insert connection thread to add rows to the queue.

This page is licensed: CC BY-SA / Gnu FDL

Event Scheduler Thread States

This article documents thread states that are related to event scheduling and execution. These include the Event Scheduler thread, threads that terminate the Event Scheduler, and threads for executing events.

These correspond to the `STATE` values listed by the SHOW PROCESSLIST statement or in the Information Schema PROCESSLIST Table as well as the `PROCESSLIST_STATE` value listed in the Performance Schema threads Table

Value	Description
Clearing	Thread is terminating.
Initialized	Thread has be initialized.
Waiting for next activation	The event queue contains items, but the next activation is at some time in the future.
Waiting for scheduler to stop	Waiting for the event scheduler to stop after issuing SET GLOBAL event_scheduler=OFF.
Waiting on empty queue	Sleeping, as the event scheduler's queue is empty.

This page is licensed: CC BY-SA / Gnu FDL

Galera Cluster Thread States

This article documents thread states that are specific to MariaDB Enterprise Cluster and appear in the SHOW PROCESSLIST when nodes are performing cluster-specific operations. These states enable monitoring of session status within clustered environments.

The following table lists the thread states present in Galera Cluster and their descriptions:

Thread State	Description
waiting to execute in isolation	The thread is waiting to execute a transaction in isolation mode.
waiting for TOI DDL	The thread is waiting for a Total Order Isolation Data Definition Language (DDL) operation to complete.
waiting for flow control	The thread is paused due to Galera flow control, which regulates replication throughput.
waiting for certification	The transaction is waiting for Galera transaction certification before it can be applied to avoid conflict with other transactions.

These states contribute in the identification of synchronization delays and performance bottlenecks in a Galera Cluster framework.

> These states were introduced in MariaDB Enterprise Server 11.4 and are also available in MariaDB Community Server 11.0.3 and later.

General Thread States

This article documents the major general thread states. More specific lists related to delayed inserts, replication, the query cache and the event scheduler are listed in:

- Event Scheduler Thread States
- Query Cache Thread States
- Master Thread States
- Slave Connection Thread States
- Slave I/O Thread States
- Slave SQL Thread States

These correspond to the `STATE` values listed by the SHOW PROCESSLIST statement or in the Information Schema PROCESSLIST Table as well as the `PROCESSLIST_STATE` value listed in the Performance Schema threads Table

Value	Description
After create	The function that created (or tried to create) a table (temporary or non-temporary) has just ended.
Analyzing	Calculating table key distributions, such as when running an ANALYZE TABLE statement.
checking permissions	Checking to see whether the permissions are adequate to perform the statement.
Checking table	Checking the table.
cleaning up	Preparing to reset state variables and free memory after executing a command.

Value	Description
closing tables	Flushing the changes to disk and closing the table. This state will only persist if the disk is full or under extremely high load.
converting HEAP to Aria	Converting an internal MEMORY temporary table into an on-disk Aria temporary table.
converting HEAP to MyISAM	Converting an internal MEMORY temporary table into an on-disk MyISAM temporary table.
copy to tmp table	A new table has been created as part of an ALTER TABLE statement, and rows are about to be copied into it.
Copying to group table	Sorting the rows by group and copying to a temporary table, which occurs when a statement has different GROUP BY and ORDER BY criteria.
Copying to tmp table	Copying to a temporary table in memory.
Copying to tmp table on disk	Copying to a temporary table on disk, as the resultset is too large to fit into memory.
Creating index	Processing an ALTER TABLE … ENABLE KEYS for an Aria or MyISAM table.
Creating sort index	Processing a SELECT statement resolved using an internal temporary table.
creating table	Creating a table (temporary or non-temporary).
Creating tmp table	Creating a temporary table (in memory or on-disk).
deleting from main table	Deleting from the first table in a multi-table delete, saving columns and offsets for use in deleting from the other tables.
deleting from reference tables	Deleting matched rows from secondary reference tables as part of a multi-table delete.
discard_or_import_tablespace	Processing an ALTER TABLE … IMPORT TABLESPACE or ALTER TABLE … DISCARD TABLESPACE statement.
end	State before the final cleanup of an ALTER TABLE, CREATE VIEW, DELETE, INSERT, SELECT, or UPDATE statement.
executing	Executing a statement.
Execution of init_command	Executing statements specified by the –init_command mariadb client option.

Value	Description
filling schema table	A table in the information_schema database is being built.
freeing items	Freeing items from the query cache after executing a command. Usually followed by the cleaning up state.
Flushing tables	Executing a FLUSH TABLES statement and waiting for other threads to close their tables.
FULLTEXT initialization	Preparing to run a full-text search. This includes running the fulltext search (MATCH … AGAINST) and creating a list of the result in memory
init	About to initialize an ALTER TABLE, DELETE, INSERT, SELECT, or UPDATE statement. Could be performaing query cache cleanup, or flushing the binary log or InnoDB log.
Killed	Thread will abort next time it checks the kill flag. Requires waiting for any locks to be released.
Locked	Query has been locked by another query.
logging slow query	Writing statement to the slow query log.
NULL	State used for SHOW PROCESSLIST.
login	Connection thread has not yet been authenticated.
manage keys	Enabling or disabling a table index.
Opening table[s]	Trying to open a table. Usually very quick unless the limit set by table_open_cache has been reached, or an ALTER TABLE or LOCK TABLE is in progress.
optimizing	Server is performing initial optimizations in for a query.
preparing	State occurring during query optimization.
Purging old relay logs	Relay logs that are no longer needed are being removed.
query end	Query has finished being processed, but items have not yet been freed (the freeing items state.
Reading file	Server is reading the file (for example during LOAD DATA INFILE).
Reading from net	Server is reading a network packet.
Removing duplicates	Duplicated rows being removed before sending to the client. This happens when SELECT DISTINCT is used in a way that the distinct operation could not be optimized at an earlier point.
removing tmp table	Removing an internal temporary table after processing a SELECT statement.
rename	Renaming a table.
rename result table	Renaming a table that results from an ALTER TABLE statement having created a new table.

Value	Description
Reopen tables	Table is being re-opened after thread obtained a lock but the underlying table structure had changed, so the lock was released.
Repair by sorting	Indexes are being created with the use of a sort. Much faster than the related Repair with keycache.
Repair done	Multi-threaded repair has been completed.
Repair with keycache	Indexes are being created through the key cache, one-by-one. Much slower than the related Repair by sorting.
Rolling back	A transaction is being rolled back.
Saving state	New table state is being saved. For example, after, analyzing a MyISAM table, the key distributions, rowcount etc. are saved to the .MYI file.
Searching rows for update	Finding matching rows before performing an UPDATE, which is needed when the UPDATE would change the index used for the UPDATE
Sending data	Sending data to the client as part of processing a SELECT statement or other statements that returns data like INSERT … RETURNING . Often the longest-occurring state as it also include all reading from tables and disk read activities. Where an aggregation or un-indexed filtering occurs there is significantly more rows read than what is sent to the client.
setup	Setting up an ALTER TABLE operation.
Sorting for group	Sorting as part of a GROUP BY
Sorting for order	Sorting as part of an ORDER BY
Sorting index	Sorting index pages as part of a table optimization operation.
Sorting result	Processing a SELECT statement using a non-temporary table.
statistics	Calculating statistics as part of deciding on a query execution plan. Usually a brief state unless the server is disk-bound.
System lock	Requesting or waiting for an external lock for a specific table. The storage engine determines what kind of external lock to use. For example, the MyISAM storage engine uses file-based locks. However, MyISAM's external locks are disabled by default, due to the default value of the skip_external_locking system variable. Transactional storage engines such as InnoDB also register the transaction or statement with MariaDB's transaction coordinator while in this thread state. See MDEV-19391 for more information about that.
Table lock	About to request a table's internal lock after acquiring the table's external lock. This thread state occurs after the System lock thread state.
update	About to start updating table.
Updating	Searching for and updating rows in a table.
updating main table	Updating the first table in a multi-table update, and saving columns and offsets for use in the other tables.
updating reference tables	Updating the secondary (reference) tables in a multi-table update

Value	Description
updating status	This state occurs after a query's execution is complete. If the query's execution time exceeds long_query_time, then Slow_queries is incremented, and if the slow query log is enabled, then the query is logged. If the SERVER_AUDIT plugin is enabled, then the query is also logged into the audit log at this stage. If the userstats plugin is enabled, then CPU statistics are also updated at this stage.
User lock	About to request or waiting for an advisory lock from a GET LOCK() call. For SHOW PROFILE, means requesting a lock only.
User sleep	A SLEEP() call has been invoked.
Waiting for commit lock	FLUSH TABLES WITH READ LOCK is waiting for a commit lock, or a statement resulting in an explicit or implicit commit is waiting for a read lock to be released. This state was called Waiting for all running commits to finish in earlier versions.
Waiting for global read lock	Waiting for a global read lock.
Waiting for table level lock	External lock acquired,and internal lock about to be requested. Occurs after the System lock state. In earlier versions, this was called Table lock.
Waiting for xx lock	Waiting to obtain a lock of type xx.
Waiting on cond	Waiting for an unspecified condition to occur.
Writing to net	Writing a packet to the network.

This page is licensed: CC BY-SA / Gnu FDL

Master Thread States

This article documents thread states that are related to replication master threads. These correspond to the `STATE` values listed by the SHOW PROCESSLIST statement or in the Information Schema PROCESSLIST Table as well as the `PROCESSLIST_STATE` value listed in the Performance Schema threads Table.

Value	Description
Finished reading one binlog; switching to next binlog	After completing one binary log, the next is being opened for sending to the slave.
Master has sent all binlog to slave; waiting for binlog to be updated	All events have been read from the binary logs and sent to the slave. Now waiting for the binary log to be updated with new events.
Sending binlog event to slave	An event has been read from the binary log, and is now being sent to the slave.
Waiting to finalize termination	State that only occurs very briefly while the thread is terminating.

This page is licensed: CC BY-SA / Gnu FDL

Query Cache Thread States

This article documents thread states that are related to the Query Cache. These correspond to the `STATE` values listed by the SHOW PROCESSLIST statement or in the Information Schema PROCESSLIST Table as well as the `PROCESSLIST_STATE` value listed in the Performance Schema threads Table.

Value	Description
checking privileges on cached query	Checking whether the user has permission to access a result in the query cache.
checking query cache for query	Checking whether the current query exists in the query cache.
invalidating query cache entries	Marking query cache entries as invalid as the underlying tables have changed.
sending cached result to client	A result found in the query cache is being sent to the client.
storing result in query cache	Saving the result of a query into the query cache.
Waiting for query cache lock	Waiting to take a query cache lock.

This page is licensed: CC BY-SA / Gnu FDL

Replica I/O Thread States

This article documents thread states that are related to replica I/O threads. These correspond to the `Slave_IO_State` shown by SHOW REPLICA STATUS and the `STATE` values listed by the SHOW PROCESSLIST statement or in the Information Schema PROCESSLIST Table as well as the `PROCESSLIST_STATE` value listed in the Performance Schema threads Table.

Value	Description
Checking master version	Checking the primary's version, which only occurs very briefly after establishing a connection with the primary.
Connecting to master	Attempting to connect to primary.
Queueing master event to the relay log	Event is being copied to the relay log after being read, where it can be processed by the SQL thread.
Reconnecting after a failed binlog dump request	Attempting to reconnect to the primary after a previously failed binary log dump request.
Reconnecting after a failed master event read	Attempting to reconnect to the primary after a previously failed request. After successfully connecting, the state will change to Waiting for master to send event.
Registering slave on master	Registering the replica on the primary, which only occurs very briefly after establishing a connection with the primary.
Requesting binlog dump	Requesting the contents of the binary logs from the given log file name and position. Only occurs very briefly after establishing a connection with the primary.
Waiting for master to send event	Waiting for binary log events to arrive after successfully connecting. If there are no new events on the primary, this state can persist for as many seconds as specified by the slave_net_timeout system variable, after which the thread will reconnect. Prior to MariaDB 10.6.18, MariaDB 10.11.8, MariaDB 11.0.6, MariaDB 11.1.5, MariaDB 11.2.4 and MariaDB 11.4.2, the time was from SLAVE START. From these versions, the time is since reading the last event.
Waiting for slave mutex on exit	Waiting for replica mutex while the thread is stopping. Only occurs very briefly.
Waiting for the slave SQL thread to free enough relay log space.	Relay log has reached its maximum size, determined by relay_log_space_limit (no limit by default), so waiting for the SQL thread to free up space by processing enough relay log events.
Waiting for master update	State before connecting to primary.

Value	Description
Waiting to reconnect after a failed binlog dump request	Waiting to reconnect after a binary log dump request has failed due to disconnection. The length of time in this state is determined by the MASTER_CONNECT_RETRY clause of the CHANGE MASTER TO statement.
Waiting to reconnect after a failed master event read	Sleeping while waiting to reconnect after a disconnection error. The time in seconds is determined by the MASTER_CONNECT_RETRY clause of the CHANGE MASTER TO statement.

Replica Connection Thread States

This article documents thread states that are related to connection threads that occur on a replicatioin replica. These correspond to the `STATE` values listed by the SHOW PROCESSLIST statement or in the Information Schema PROCESSLIST Table as well as the `PROCESSLIST_STATE` value listed in the Performance Schema threads Table.

Value	Description
Changing master	Processing a CHANGE MASTER TO statement.
Killing slave	Processing a STOP SLAVE statement.
Opening master dump table	A table has been created from a master dump and is now being opened.
Reading master dump table data	After the table created by a master dump (the Opening master dump table state) the table is now being read.
Rebuilding the index on master dump table	After the table created by a master dump has been opened and read (the Reading master dump table data state), the index is built.

This page is licensed: CC BY-SA / Gnu FDL

Replica SQL Thread States

This article documents thread states that are related to replication slave SQL threads. These correspond to the `Slave_SQL_State` shown by SHOW SLAVE STATUS as well as the `STATE` values listed by the SHOW PROCESSLIST statement and the Information Schema PROCESSLIST as well as the `PROCESSLIST_STATE` value listed in the Performance Schema threads Table.

Value	Description
Apply log event	Log event is being applied.
Making temp file	Creating a temporary file containing the row data as part of a LOAD DATA INFILE statement.
Reading event from the relay log	Reading an event from the relay log in order to process the event.
Slave has read all relay log, waiting for the slave I/O thread to update it	All relay log events have been processed, now waiting for the I/O thread to write new events to the relay log.
Waiting for work from SQL thread	In parallel replication the worker thread is waiting for more things from the SQL thread.
Waiting for prior transaction to start commit before starting next transaction	In parallel replication the worker thread is waiting for conflicting things to end before starting executing.
Waiting for worker threads to be idle	Happens in parallel replication when moving to a new binary log after a master restart. All slave temporary files are deleted, and worker threads are restarted.
Waiting due to global read lock	In parallel replication when worker threads are waiting for a global read lock to be released.

Value	Description
Waiting for worker threads to pause for global read lock	FLUSH TABLES WITH READ LOCK is waiting for worker threads to finish what they are doing.
Waiting while replication worker thread pool is busy	Happens in parallel replication during a FLUSH TABLES WITH READ LOCK or when changing number of parallel workers.
Waiting for other master connection to process GTID received on multiple master connections	A worker thread noticed that there is already another thread executing the same GTID from another connection and it's waiting for the other to complete.
Waiting for slave mutex on exit	Thread is stopping. Only occurs very briefly.
Waiting for the next event in relay log	State before reading next event from the relay log.

MariaDB Internal Optimizations

See Fair Choice Between Range and Index_merge Optimizations.

How the optimizer chooses fairly between the range and index_merge access methods.

See Multi Range Read Optimization.

The Multi-Range Read (MRR) optimization, which improves performance for I/O-bound queries scanning many rows.

This page is licensed: CC BY-SA / Gnu FDL

Fair Choice Between Range and Index_merge Optimizations

`index_merge` is a method used by the optimizer to retrieve rows from a single table using several index scans. The results of the scans are then merged.

When using EXPLAIN, if `index_merge` is the plan chosen by the optimizer, it will show up in the "type" column. For example:

```
MariaDB [ontime]> SELECT COUNT(*) FROM ontime;
+--------+
|count(*)|
+--------+
| 1578171|
+--------+

MySQL [ontime]> EXPLAIN SELECT * FROM ontime WHERE (Origin='SEA' OR Dest='SEA');
+--+-----------+------+-----------+-------------+-----------+-------+----+-----+-------------------------
-------------+
|id|select_type|table |type       |possible_keys|key        |key_len|ref |rows |Extra
|
+--+-----------+------+-----------+-------------+-----------+-------+----+-----+-------------------------
-------------+
| 1|SIMPLE     |ontime|index_merge|Origin,Dest  |Origin,Dest|6,6    |NULL|92800|Using union
(Origin,Dest); Using where|
+--+-----------+------+-----------+-------------+-----------+-------+----+-----+-------------------------
-------------+
```

The "rows" column gives us a way to compare efficiency between `index_merge` and other plans.

It is sometimes necessary to discard index_merge in favor of a different plan to avoid a combinatorial explosion of possible range and/or index_merge strategies. But, the old logic in MySQL for when index_merge was rejected caused some good index_merge plans to not even be considered. Specifically, additional `AND` predicates in `WHERE` clauses could cause an index_merge plan to be rejected in favor of a less efficient plan. The slowdown could be anywhere from 10x to over 100x. Here are two examples (based on the previous query) using MySQL:

```
MySQL [ontime]> EXPLAIN SELECT * FROM ontime WHERE (Origin='SEA' OR Dest='SEA') AND securitydelay=0;
+--+-----------+------+----+------------------------+-------------+-------+-----+------+-----------+
|id|select_type|table |type|possible_keys           |key          |key_len|ref  |rows  |Extra      |
+--+-----------+------+----+------------------------+-------------+-------+-----+------+-----------+
| 1|SIMPLE     |ontime|ref |Origin,Dest,SecurityDelay|SecurityDelay|5      |const|791546|Using where|
+--+-----------+------+----+------------------------+-------------+-------+-----+------+-----------+

MySQL [ontime]> EXPLAIN SELECT * FROM ontime WHERE (Origin='SEA' OR Dest='SEA') AND depdelay < 12*60;
+--+-----------+------+----+--------------------+----+-------+----+-------+-----------+
|id|select_type|table |type|possible_keys       |key |key_len|ref |rows   |Extra      |
+--+-----------+------+----+--------------------+----+-------+----+-------+-----------+
| 1|SIMPLE     |ontime|ALL |Origin,DepDelay,Dest|NULL|NULL   |NULL|1583093|Using where|
+--+-----------+------+----+--------------------+----+-------+----+-------+-----------
```

In the above output, the “rows” column shows that the first is almost 10x less efficient and the second is over 15x less efficient than `index_merge`.

Starting in MariaDB 5.3, the optimizer will delay discarding potential `index_merge` plans until the point where it is really necessary.

By not discarding potential `index_merge` plans until absolutely necessary, the two queries stay just as efficient as the original:

```
MariaDB [ontime]> EXPLAIN SELECT * FROM ontime WHERE (Origin='SEA' OR Dest='SEA');
+--+-----------+------+-----------+-------------+-----------+-------+----+-----+-------------------------
------------+
|id|select_type|table |type       |possible_keys|key        |key_len|ref |rows |Extra
|
+--+-----------+------+-----------+-------------+-----------+-------+----+-----+-------------------------
------------+
| 1|SIMPLE     |ontime|index_merge|Origin,Dest  |Origin,Dest|6,6    |NULL|92800|Using union(Origin,Dest);
Using where|
+--+-----------+------+-----------+-------------+-----------+-------+----+-----+-------------------------
------------+

MariaDB [ontime]> EXPLAIN SELECT * FROM ontime WHERE (Origin='SEA' OR Dest='SEA') AND securitydelay=0;
+--+-----------+------+-----------+-------------------------+-----------+-------+----+-----+-------------
------------------------+
|id|select_type|table |type       |possible_keys            |key        |key_len|ref |rows |Extra
|
+--+-----------+------+-----------+-------------------------+-----------+-------+----+-----+-------------
------------------------+
| 1|SIMPLE     |ontime|index_merge|Origin,Dest,SecurityDelay|Origin,Dest|6,6    |NULL|92800|Using
union(Origin,Dest); Using where|
+--+-----------+------+-----------+-------------------------+-----------+-------+----+-----+-------------
------------------------+

MariaDB [ontime]> EXPLAIN SELECT * FROM ontime WHERE (Origin='SEA' OR Dest='SEA') AND depdelay < 12*60;
+--+-----------+------+-----------+--------------------+-----------+-------+----+-----+------------------
--------------------+
|id|select_type|table |type       |possible_keys       |key        |key_len|ref |rows |Extra
|
+--+-----------+------+-----------+--------------------+-----------+-------+----+-----+------------------
--------------------+
| 1|SIMPLE     |ontime|index_merge|Origin,DepDelay,Dest|Origin,Dest|6,6    |NULL|92800|Using
union(Origin,Dest); Using where|
+--+-----------+------+-----------+--------------------+-----------+-------+----+-----+------------------
--------------------+
```

This new behavior is always on and there is no need to enable it. There are no known issues or gotchas with this new optimization.

This page is licensed: CC BY-SA / Gnu FDL

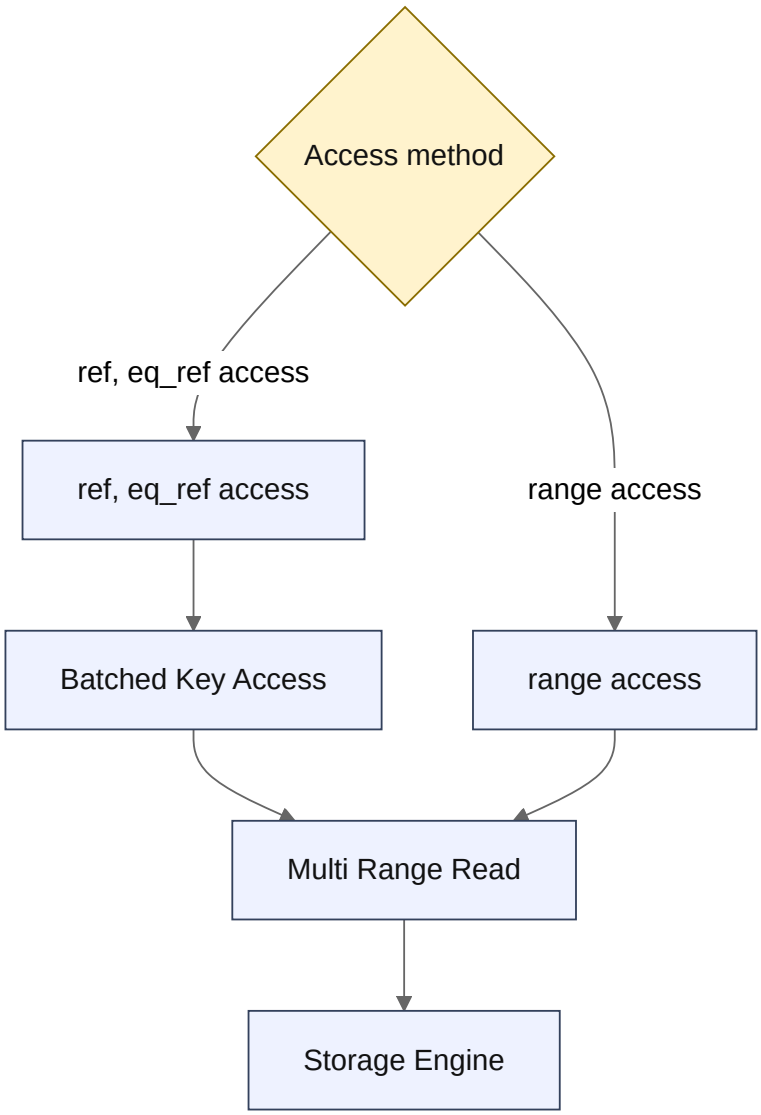
Multi Range Read Optimization

Multi Range Read is an optimization aimed at improving performance for IO-bound queries that need to scan lots of rows.

Multi Range Read can be used with

- `range` access
- `ref` and `eq_ref` access, when they are using Batched Key Access

as shown in this diagram:



Possible ways to use MRR: range access, or ref/eq_ref access via Batched Key Access, both feed into Multi Range Read.

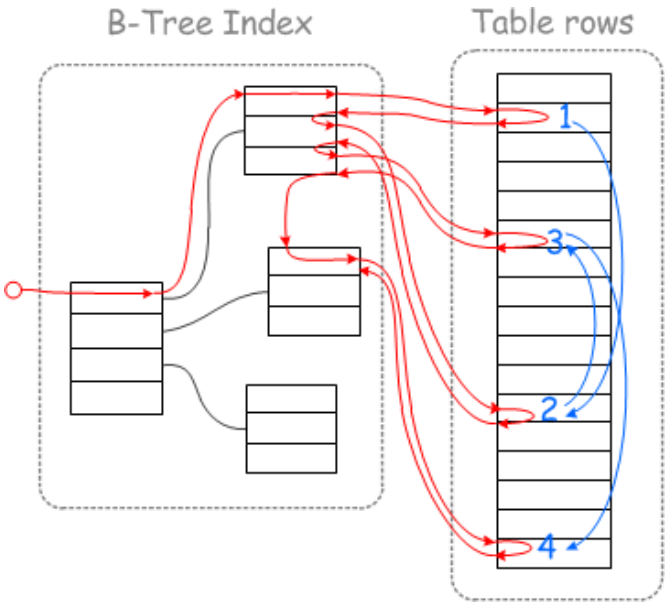
The Idea

Case 1: Rowid Sorting for Range Access

Consider a range query:

```
EXPLAIN SELECT * FROM tbl WHERE tbl.key1 BETWEEN 1000 AND 2000;
+----+-------------+-------+-------+---------------+------+---------+------+------+----------------------
-+
| id | select_type | table | type  | possible_keys | key  | key_len | ref  | rows | Extra
|
+----+-------------+-------+-------+---------------+------+---------+------+------+----------------------
-+
|  1 | SIMPLE      | tbl   | range | key1          | key1 | 5       | NULL |  960 | Using index condition
|
+----+-------------+-------+-------+---------------+------+---------+------+------+----------------------
-+
```

When this query is executed, disk IO access pattern will follow the red line in this figure:



no-mrr-access-pattern

Execution will hit the table rows in random places, as marked with the blue line/numbers in the figure.

When the table is sufficiently big, each table record read will need to actually go to disk (and be served from buffer pool or OS cache), and query execution will be too slow to be practical. For example, a 10,000 RPM disk drive is able to make 167 seeks per second, so in the worst case, query execution will be capped at reading about 167 records per second.

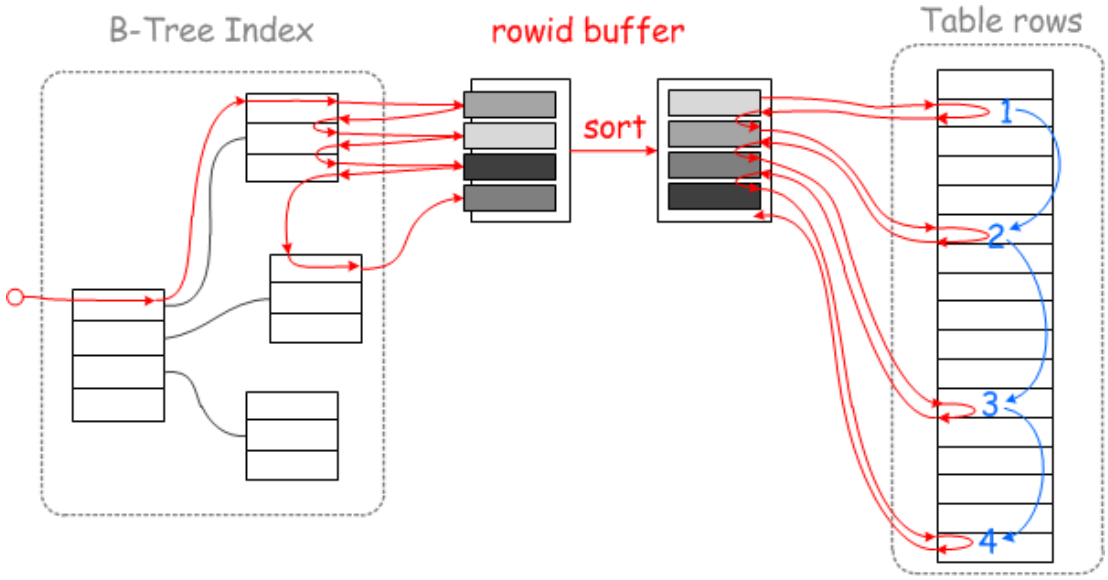
SSD drives do not need to do disk seeks, so they will not be hurt as badly, however the performance will still be poor in many cases.

Multi-Range-Read optimization aims to make disk access faster by sorting record read requests and then doing one ordered disk sweep. If one enables Multi Range Read, `EXPLAIN` will show that a "`Rowid-ordered scan`" is used:

```
SET optimizer_switch='mrr=ON';
Query OK, 0 rows affected (0.06 sec)

EXPLAIN SELECT * FROM tbl WHERE tbl.key1 BETWEEN 1000 AND 2000;
+----+-------------+-------+-------+---------------+------+---------+------+------+----------------------
----------------------+
| id | select_type | table | type  | possible_keys | key  | key_len | ref  | rows | Extra
|
+----+-------------+-------+-------+---------------+------+---------+------+------+----------------------
----------------------+
|  1 | SIMPLE      | tbl   | range | key1          | key1 | 5       | NULL |  960 | Using index
condition; Rowid-ordered scan |
+----+-------------+-------+-------+---------------+------+---------+------+------+----------------------
----------------------+
1 row in set (0.03 sec)
```

and the execution will proceed as follows:



mrr-access-pattern

Reading disk data sequentially is generally faster, because

- Rotating drives do not have to move the head back and forth
- One can take advantage of IO-prefetching done at various levels
- Each disk page will be read exactly once, which means we won't rely on disk cache (or buffer pool) to save us from reading the same page multiple times.

The above can make a huge difference on performance. There is also a catch, though:

- If you're scanning small data ranges in a table that is sufficiently small so that it completely fits into the OS disk cache, then you may observe that the only effect of MRR is that extra buffering/sorting adds some CPU overhead.
- `LIMIT n` and `ORDER BY ... LIMIT n` queries with small values of `n` may become slower. The reason is that MRR reads data in disk order, while `ORDER BY ... LIMIT n` wants first `n` records in index order.

Case 2: Rowid Sorting for Batched Key Access

Batched Key Access can benefit from rowid sorting in the same way as range access does. If one has a join that uses index lookups:

```
EXPLAIN SELECT * FROM t1,t2 WHERE t2.key1=t1.col1;
+----+-------------+-------+------+---------------+------+---------+--------------+------+-------------+
| id | select_type | table | type | possible_keys | key  | key_len | ref          | rows | Extra       |
+----+-------------+-------+------+---------------+------+---------+--------------+------+-------------+
|  1 | SIMPLE      | t1    | ALL  | NULL          | NULL | NULL    | NULL         | 1000 | Using where |
|  1 | SIMPLE      | t2    | ref  | key1          | key1 | 5       | test.t1.col1 |    1 |             |
+----+-------------+-------+------+---------------+------+---------+--------------+------+-------------+
2 rows in set (0.00 sec)
```

Execution of this query will cause table `t2` to be hit in random locations by lookups made through `t2.key1=t1.col`. If you enable Multi Range and Batched Key Access, you will get table `t2` to be accessed using a `Rowid-ordered scan`:

```
SET optimizer_switch='mrr=ON';
Query OK, 0 rows affected (0.06 sec)

SET join_cache_level=6;
Query OK, 0 rows affected (0.00 sec)

EXPLAIN SELECT * FROM t1,t2 WHERE t2.key1=t1.col1;
+----+-------------+-------+------+---------------+------+---------+--------------+------+--------------
----------------------------------------+
| id | select_type | table | type | possible_keys | key  | key_len | ref          | rows | Extra
|
+----+-------------+-------+------+---------------+------+---------+--------------+------+--------------
----------------------------------------+
|  1 | SIMPLE      | t1    | ALL  | NULL          | NULL | NULL    | NULL         | 1000 | Using where
|
|  1 | SIMPLE      | t2    | ref  | key1          | key1 | 5       | test.t1.col1 |    1 | Using join
buffer (flat, BKA join); Rowid-ordered scan |
+----+-------------+-------+------+---------------+------+---------+--------------+------+--------------
----------------------------------------+
2 rows in set (0.00 sec)
```

The benefits will be similar to those listed for `range` access.

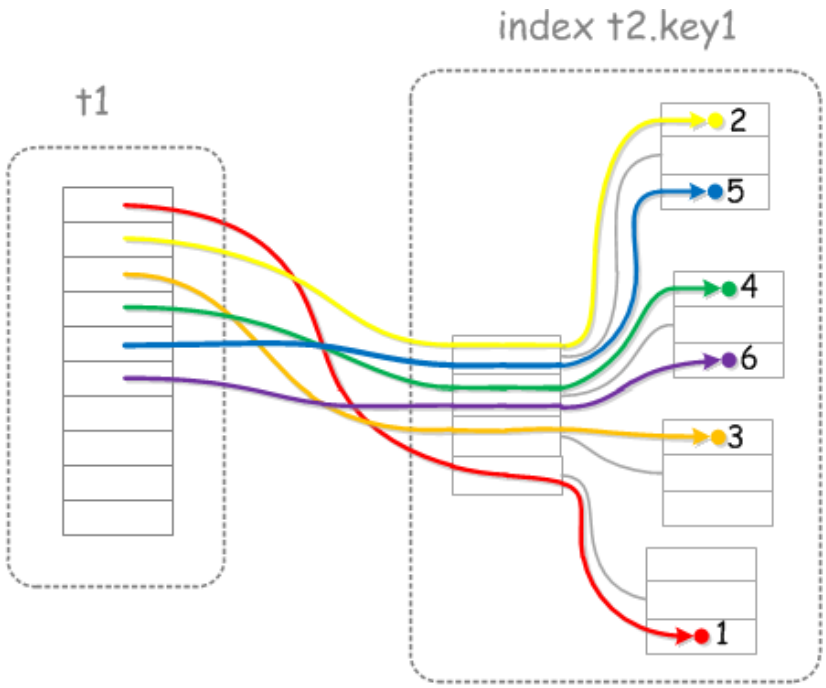
An additional source of speedup is this property: if there are multiple records in `t1` that have the same value of `t1.col1`, then regular Nested-Loops join will make multiple index lookups for the same value of `t2.key1=t1.col1`. The lookups may or may not hit the cache, depending on how big the join is. With Batched Key Access and Multi-Range Read, no duplicate index lookups will be made.

Case 3: Key Sorting for Batched Key Access

Let us consider again the nested loop join example, with `ref` access on the second table:

```
EXPLAIN SELECT * FROM t1,t2 WHERE t2.key1=t1.col1;
+----+-------------+-------+------+---------------+------+---------+--------------+------+-------------+
| id | select_type | table | type | possible_keys | key  | key_len | ref          | rows | Extra       |
+----+-------------+-------+------+---------------+------+---------+--------------+------+-------------+
|  1 | SIMPLE      | t1    | ALL  | NULL          | NULL | NULL    | NULL         | 1000 | Using where |
|  1 | SIMPLE      | t2    | ref  | key1          | key1 | 5       | test.t1.col1 |    1 |             |
+----+-------------+-------+------+---------------+------+---------+--------------+------+-------------+
```

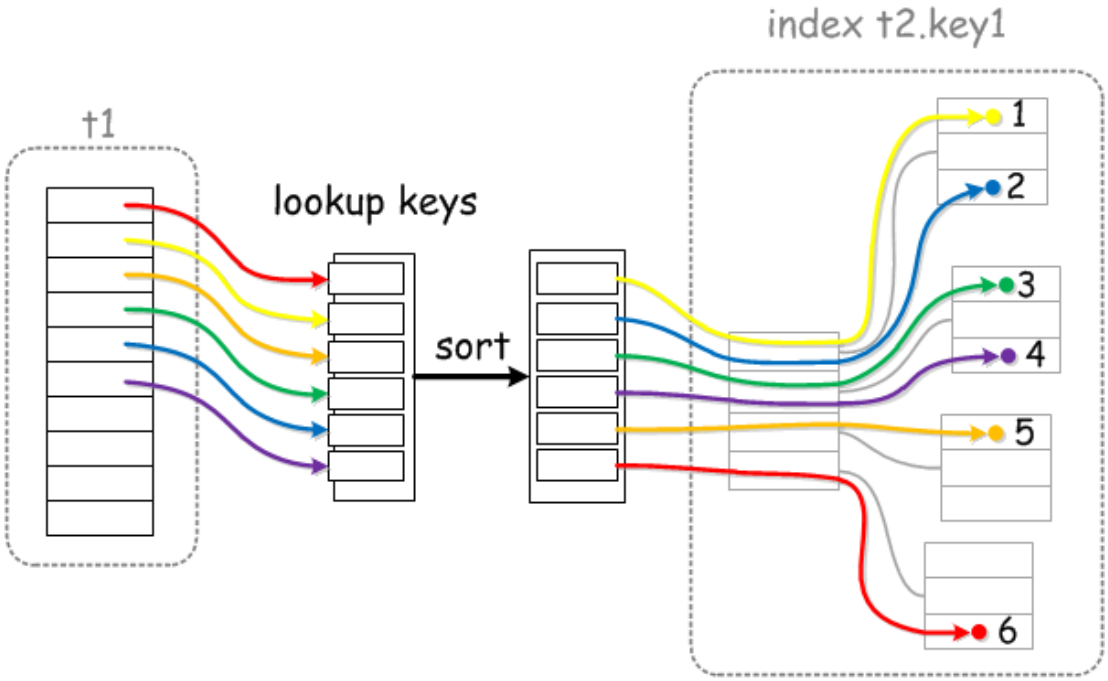
Execution of this query plan will cause random hits to be made into the index `t2.key1`, as shown in this picture:



Regular Nested Loops Join will hit the index at random

key-sorting-regular-nl-join

In particular, on step #5 we'll read the same index page that we've read on step #2, and the page we've read on step #4 will be re-read on step#6. If all pages you're accessing are in the cache (in the buffer pool, if you're using InnoDB, and in the key cache, if you're using MyISAM), this is not a problem. However, if your hit ratio is poor and you're going to hit the disk, it makes sense to sort the lookup keys, like shown in this figure:



With *Batched Nested Loops Join* and *Key-Ordered retrieval*, index lookups are done in one "sweep"

key-sorting-join

This is roughly what `Key-ordered scan` optimization does. In EXPLAIN, it looks as follows:

```
SET optimizer_switch='mrr=ON,mrr_sort_keys=ON';
Query OK, 0 rows affected (0.00 sec)

SET join_cache_level=6;
Query OK, 0 rows affected (0.02 sec)
EXPLAIN SELECT * FROM t1,t2 WHERE t2.key1=t1.col1\G
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        TABLE: t1
         type: ALL
possible_keys: a
          KEY: NULL
      key_len: NULL
          ref: NULL
         ROWS: 1000
        Extra: USING WHERE
*************************** 2. row ***************************
           id: 1
  select_type: SIMPLE
        TABLE: t2
         type: ref
possible_keys: key1
          KEY: key1
      key_len: 5
          ref: test.t1.col1
         ROWS: 1
        Extra: USING JOIN buffer (flat, BKA JOIN); KEY-ordered Rowid-ordered scan
2 rows in set (0.00 sec)
```

((TODO: a note about why sweep-read over InnoDB's clustered primary index scan (which is, actually the whole InnoDB table itself) will use `Key-ordered scan` algorithm, but not `Rowid-ordered scan` algorithm, even though conceptually they are the same thing in this case))

Buffer Space Management

As was shown above, Multi Range Read requires sort buffers to operate. The size of the buffers is limited by system variables. If MRR has to process more data than it can fit into its buffer, it will break the scan into multiple passes. The more passes are made, the less is the speedup though, so one needs to balance between having too big buffers (which consume lots of memory) and too small buffers (which limit the possible speedup).

Range Access

When MRR is used for `range` access, the size of its buffer is controlled by the mrr_buffer_size system variable. Its value specifies how much space can be used for each table. For example, if there is a query which is a 10-way join and MRR is used for each table, `10*@@mrr_buffer_size` bytes may be used.

Batched Key Access

When Multi Range Read is used by Batched Key Access, then buffer space is managed by BKA code, which will automatically provide a part of its buffer space to MRR. You can control the amount of space used by BKA by setting

- join_buffer_size to limit how much memory BKA uses for each table, and
- join_buffer_space_limit to limit the total amount of memory used by BKA in the join.

Status Variables

There are three status variables related to Multi Range Read:

Variable name	Meaning
Handler_mrr_init	Counts how many Multi Range Read scans were performed

Variable name	Meaning
Handler_mrr_key_refills	Number of times key buffer was refilled (not counting the initial fill)
Handler_mrr_rowid_refills	Number of times rowid buffer was refilled (not counting the initial fill)

Non-zero values of `Handler_mrr_key_refills` and/or `Handler_mrr_rowid_refills` mean that Multi Range Read scan did not have enough memory and had to do multiple key/rowid sort-and-sweep passes. The greatest speedup is achieved when Multi Range Read runs everything in one pass, if you see lots of refills it may be beneficial to increase sizes of relevant buffers mrr_buffer_size join_buffer_size and join_buffer_space_limit

Effect on Other Status Variables

When a Multi Range Read scan makes an index lookup (or some other "basic" operation), the counter of the "basic" operation, e.g. Handler_read_key, will also be incremented. This way, you can still see total number of index accesses, including those made by MRR. Per-user/table/index statistics counters also include the row reads made by Multi Range Read scans.

Why Using Multi Range Read Can Cause Higher Values in Status Variables

Multi Range Read is used for scans that do full record reads (i.e., they are not "Index only" scans). A regular non-index-only scan will read

1. an index record, to get a rowid of the table record
2. a table record
   Both actions will be done by making one call to the storage engine, so the effect of the call will be that the relevan `Handler_read_XXX` counter will be incremented BY ONE, and Innodb_rows_read will be incremented BY ONE.

Multi Range Read will make separate calls for steps #1 and #2, causing TWO increments to `Handler_read_XXX` counters and TWO increments to `Innodb_rows_read` counter. To the uninformed, this looks as if Multi Range Read was making things worse. Actually, it doesn't - the query will still read the same index/table records, and actually Multi Range Read may give speedups because it reads data in disk order.

Multi Range Read Factsheet

- Multi Range Read is used by
  - `range` access method for range scans.
  - Batched Key Access for joins
- Multi Range Read can cause slowdowns for small queries over small tables, so it is disabled by default.
- There are two strategies:
  - Rowid-ordered scan
  - Key-ordered scan
- : and you can tell if either of them is used by checking the `Extra` column in `EXPLAIN` output.
- There are three optimizer_switch flags you can switch ON:
  - `mrr=on` - enable MRR and rowid ordered scans
  - `mrr_sort_keys=on` - enable Key-ordered scans (you must also set `mrr=on` for this to have any effect)
  - `mrr_cost_based=on` - enable cost-based choice whether to use MRR. Currently not recommended, because cost model is not sufficiently tuned yet.

Differences from MySQL

- MySQL supports only `Rowid ordered scan` strategy, which it shows in `EXPLAIN` as `Using MRR`.
- EXPLAIN in MySQL shows `Using MRR`, while in MariaDB it may show

    - `Rowid-ordered scan`
    - `Key-ordered scan`
    - `Key-ordered Rowid-ordered scan`
- MariaDB uses mrr_buffer_size as a limit of MRR buffer size for `range` access, while MySQL uses read_rnd_buffer_size.
- MariaDB has three MRR counters: Handler_mrr_init, `Handler_mrr_extra_rowid_sorts`, `Handler_mrr_extra_key_sorts`, while MySQL has only `Handler_mrr_init`, and it will only count MRR scans that were used by BKA. MRR scans used by range access are not counted.

Operating System Optimizations

See Filesystem Optimizations.

Filesystem choices and settings that affect MariaDB Server performance.

See Storage I/O: Buffering and Persistence.

Defines the OS-agnostic terms MariaDB documentation uses for disk I/O — unbuffered I/O, write-through, persist — and shows how each one maps to Unix-like and Windows mechanisms.

This page is licensed: CC BY-SA / Gnu FDL

Filesystem Optimizations

Suitability of Filesystems

The filesystem is not the most important aspect of MariaDB performance. More important are the available memory (RAM), the drive speed, and the system variable settings (see Hardware Optimization and System Variables).

Optimizing the filesystem can, however, make a noticeable difference in some cases. Among the best suited Linux filesystems are ext4, XFS and Btrfs. They are all included in the mainline Linux kernel and are widely supported and available on most Linux distributions.

The following theoretical file size and filesystem size limits apply to those filesystems:

Limit	ext4	XFS	Btrfs
Links	ext4	XFS	Btrfs
Max file size	16-256 TB	8 EB	16 EB
Max filesystem size	1 EB	8 EB	16 EB

Each has unique characteristics that are worth understanding to get the most from their usage.

Disabling Access Time

It's unlikely you'll need to record file access time on a database server, and mounting your filesystem with this disabled can give an easy improvement in performance. To do so, use the `noatime` option.

If you want to keep access time for log files or other system files, these can be stored on a separate drive.

Using NFS

Generally, we recommend not to use NFS (Network File System) with MariaDB, for these reasons:

- MariaDB data and log files on NFS volumes can become locked and unavailable for use. Locking issues may occur in cases where multiple instances of MariaDB access the same data directory, or when MariaDB is shut down improperly, for instance, due to a power outage. In particular, sharing a data directory among MariaDB instances is not recommended.
- Data inconsistencies due to messages received out of order or lost network traffic. To avoid this issue, use TCP with `hard` and `intr` mount options.

Using NFS within a professional SAN[29] environment or other storage system tends to offer greater reliability than using NFS outside of such an environment. However, NFS within a SAN environment may be slower than directly attached or bus-attached non-rotational storage.

Storage I/O: Buffering and Persistence

This page defines the I/O behavior terms that other MariaDB documentation pages use — *unbuffered I/O*, *write-through*, *persist to non-volatile storage* — and shows how each one maps to the underlying mechanism on Unix-like systems and Windows. Other pages refer here for the OS-level details rather than embedding system-specific flag names inline.

Why This Matters

The MariaDB server, and especially the InnoDB storage engine, needs precise control over when writes actually reach non-volatile storage. The operating system normally buffers writes in memory (the *page cache*) and flushes them to disk on its own schedule. That is fast, but unsafe for a transactional database: a power loss between the application write and the OS flush would lose committed data.

MariaDB therefore exposes configuration that lets administrators choose between OS-buffered performance and database-controlled durability. The configuration uses general I/O terms — buffering, write-through, persistence — that describe the behavior independent of the operating system. This page is the reference for what those terms mean and how each OS implements them.

Unbuffered I/O

Behavior: Reads and writes bypass the operating system's page cache. Each read fetches directly from the storage device; each write is handed to the device without keeping a copy in OS memory.

Trade-off: Avoids "double buffering" — that is, caching the same data both in MariaDB's own buffer pool and in the OS page cache, which costs memory and CPU. The trade-off is the loss of the OS's read-ahead and write-coalescing optimizations. Unbuffered I/O is most appropriate when MariaDB itself manages most of the memory available for caching data (for example, when the InnoDB buffer pool is sized to most of system RAM).

Operating system	Underlying mechanism
Unix-like	File opened with `O_DIRECT`. Supported on Linux, FreeBSD, NetBSD, Dragonfly BSD, Illumos / Solaris, and IBM AIX; not supported on OpenBSD or Apple macOS.
Windows	File opened with `FILE_FLAG_NO_BUFFERING`

Write-Through

Behavior: Every individual write call returns only after the storage layer has accepted the data for non-volatile storage. Equivalent to issuing a write followed by an immediate persist, on every single write.

Trade-off: Maximum durability per write, at the cost of write latency. The application does not need to issue a separate persist call to know that data is safe.

Operating system	Underlying mechanism
Unix-like	File opened with `O_DSYNC`. Supported on Linux, FreeBSD, NetBSD, Solaris, and IBM AIX; not supported on Dragonfly BSD (which has `O_FSYNC`, not used by MariaDB), OpenBSD, or Apple macOS.
Windows	File opened with `FILE_FLAG_WRITE_THROUGH`

Persist to Non-Volatile Storage

Behavior: After one or more buffered writes, force any data still in the OS page cache or the storage device's own write cache out to non-volatile media. The call returns only once the data is durable.

Trade-off: Lets the application batch many writes cheaply and persist them with a single explicit call, instead of paying the durability cost on every write (as write-through does). This is the foundation of MariaDB's group-commit and binary-log durability behavior.

MariaDB does not validate file access or modification timestamps anywhere, so on each platform it prefers the lighter-weight call that omits those metadata updates, falling back to the full-persist call only when the lighter one is not available.

Operating system	Underlying mechanism
Unix-like	`fdatasync()` when available (Linux, FreeBSD, Dragonfly BSD, NetBSD, OpenBSD, Solaris, IBM AIX); `fsync()` otherwise (notably Apple macOS).
Windows	`NtFlushBuffersFileEx()` with the `FLUSH_FLAGS_FILE_DATA_SYNC_ONLY` flag when available — documented for NTFS, and observed to work on ReFS as well. `FlushFileBuffers()` otherwise (older Windows versions, non-NTFS filesystems, or if the lighter call fails at run time).

Building the best INDEX for a given SELECT

The problem

You have a SELECT and you want to build the best INDEX for it. This blog is a “cookbook” on how to do that task.

- A short algorithm that works for many simpler SELECTs and helps in complex queries.
- Examples of the algorithm, plus digressions into exceptions and variants
- Finally a long list of “other cases”.

The hope is that a newbie can quickly get up to speed, and his/her INDEXes will no longer smack of “newbie”.

Many edge cases are explained, so even an expert may find something useful here.

Algorithm

Here’s the way to approach creating an INDEX, given a SELECT. Follow the steps below, gathering columns to put in the INDEX in order. When the steps give out, you usually have the ‘perfect’ index.

1. Given a WHERE with a bunch of expressions connected by AND: Include the columns (if any), in any order, that are compared to a constant and not hidden in a function.
2. You get one more chance to add to the INDEX; do the first of these that applies:

- 2a. One column used in a ‘range’ – BETWEEN, ‘>’, LIKE w/o leading wildcard, etc.
- 2b. All columns, in order, of the GROUP BY.
- 2c. All columns, in order, of the ORDER BY if there is no mixing of ASC and DESC.

Digression

This blog assumes you know the basic idea behind having an INDEX. Here is a refresher on some of the key points.

Virtually all INDEXes in MySQL are structured as BTrees
BTrees allow very efficient for

- Given a key, find the corresponding row(s);
- “Range scans” – That is start at one value for the key and repeatedly find the “next” (or “previous”) row.

A PRIMARY KEY is a UNIQUE KEY; a UNIQUE KEY is an INDEX. (“KEY” == “INDEX”.)

InnoDB “clusters” the PRIMARY KEY with the data. Hence, given the value of the PK (“PRIMARY KEY”), after drilling down the BTree to find the index entry, you have all the columns of the row when you get there. A “secondary key” (any UNIQUE or INDEX other than the PK) in InnoDB first drills down the BTree for the secondary index, where it finds a copy of the PK. Then it drills down the PK to find the row.

Every InnoDB table has a PRIMARY KEY. While there is a default if you do not specify one, it is best to explicitly provide a PK.

For completeness: MyISAM works differently. All indexes (including the PK) are in separate BTrees. The leaf node of such BTrees have a pointer (usually a byte offset) into the data file.

All discussion here assumes InnoDB tables, however most statements apply to other Engines.

First, some examples

Think of a list of names, sorted by last_name, then first_name. You have undoubtedly seen such lists, and they often have other information such as address and phone number. Suppose you wanted to look me up. If you remember my full name (‘James’ and ‘Rick’), it is easy to find my entry. If you remembered only my last name (‘James’) and first initial (‘R’). You would quickly zoom in on the Jameses and find the Rs in them. There, you might remember ‘Rick’ and ignore ‘Ronald’. But, suppose you remembered my first name (‘Rick’) and only my last initial (‘J’). Now you are in trouble. You would be scanning all the Js – Jones, Rick; Johnson, Rick; Jamison, Rick; etc, etc. That’s much less efficient.

Those equate to

```
INDEX(last_name, first_name) -- the order of the list.
    WHERE last_name = 'James' AND first_name = 'Rick'  -- best case
    WHERE last_name = 'James' AND first_name LIKE 'R%' -- pretty good
    WHERE last_name LIKE 'J%' AND first_name = 'Rick'  -- pretty bad
```

Think about this example as I talk about “=” versus “range” in the Algorithm, below.

Algorithm, step 1 (WHERE “column = const”)

- `WHERE aaa = 123 AND ...` : an INDEX starting with aaa is good.
- `WHERE aaa = 123 AND bbb = 456 AND ...` : an INDEX starting with aaa and bbb is good. In this case, it does not matter whether aaa or bbb comes first in the INDEX.
- `xxx IS NULL` : this acts like “= const” for this discussion.
- `WHERE t1.aa = 123 AND t2.bb = 456` – You must only consider columns in the current table.

Note that the expression must be of the form of `column_name` = (constant). These do not apply to this step in the Algorithm: DATE(dt) = ‘…’, LOWER(s) = ‘…’, CAST(s …) = ‘…’, x=‘…’ COLLATE…

(If there are no “=” parts AND’d in the WHERE clause, move on to step 2 without any columns in your putative INDEX.)

Algorithm, step 2

Find the first of 2a / 2b / 2c that applies; use it; then quit. If none apply, then you are through gathering columns for the index.

In some cases it is optimal to do step 1 (all equals) plus step 2c (ORDER BY).

Algorithm, step 2a (one range)

A “range” shows up as

- `aaa >= 123` – any of <, <=, >=, >; but not <>, !=

- `aaa BETWEEN 22 AND 44`
- `sss LIKE 'blah%'` – but not `sss LIKE '%blah'`
- `xxx IS NOT NULL`
  Add the column in the range to your putative INDEX.

If there are more parts to the WHERE clause, you must stop now.

Complete examples (assume nothing else comes after the snippet)

- `WHERE aaa >= 123 AND bbb = 1 ⇒ INDEX(bbb, aaa)` (WHERE order does not matter; INDEX order does)
- `WHERE aaa >= 123 ⇒ INDEX(aaa)`
- `WHERE aaa >= 123 AND ccc > 'xyz' ⇒ INDEX(aaa) or INDEX(ccc)` (only one range)
- `WHERE aaa >= 123 ORDER BY aaa ⇒ INDEX(aaa)` – Bonus: The ORDER BY will use the INDEX.
- `WHERE aaa >= 123 ORDER BY aaa ⇒ INDEX(aaa) DESC` – Same Bonus.

Algorithm, step 2b (GROUP BY)

If there is a GROUP BY, all the columns of the GROUP BY should now be added, in the specified order, to the INDEX you are building. (I do not know what happens if one of the columns is already in the INDEX.)

If you are GROUPing BY an expression (including function calls), you cannot use the GROUP BY; stop.

Complete examples (assume nothing else comes after the snippet)

- `WHERE aaa = 123 AND bbb = 1 GROUP BY ccc ⇒ INDEX(bbb, aaa, ccc) or INDEX(aaa, bbb, ccc)` (='s first, in any order; then the GROUP BY)
- `WHERE aaa >= 123 GROUP BY xxx ⇒ INDEX(aaa)` (You should have stopped with Step 2a)
- `GROUP BY x,y ⇒ INDEX(x,y)` (no WHERE)
- `WHERE aaa = 123 GROUP BY xxx, (a+b) ⇒ INDEX(aaa)` – expression in GROUP BY, so no use including even xxx.

Algorithm, step 2c (ORDER BY)

If there is a ORDER BY, all the columns of the ORDER BY should now be added, in the specified order, to the INDEX you are building.

If there are multiple columns in the ORDER BY, and there is a mixture of ASC and DESC, do not add the ORDER BY columns; they won't help; stop.

If you are ORDERing BY an expression (including function calls), you cannot use the ORDER BY; stop.

Complete examples (assume nothing else comes after the snippet)

- `WHERE aaa = 123 GROUP BY ccc ORDER BY ddd ⇒ INDEX(aaa, ccc)` – should have stopped with Step 2b
- `WHERE aaa = 123 GROUP BY ccc ORDER BY ccc ⇒ INDEX(aaa, ccc)` – the ccc will be used for both GROUP BY and ORDER BY
- `WHERE aaa = 123 ORDER BY xxx ASC, yyy DESC ⇒ INDEX(aaa)` – mixture of ASC and DESC.

The following are especially good. Normally a LIMIT cannot be applied until after lots of rows are gathered and then sorted according to the ORDER BY. But, if the INDEX gets all they way through the ORDER BY, only (OFFSET + LIMIT) rows need to be gathered. So, in these cases, you win the lottery with your new index:

- `WHERE aaa = 123 GROUP BY ccc ORDER BY ccc LIMIT 10 ⇒ INDEX(aaa, ccc)`
- `WHERE aaa = 123 ORDER BY ccc LIMIT 10 ⇒ INDEX(aaa, ccc)`
- `ORDER BY ccc LIMIT 10 ⇒ INDEX(ccc)`
- `WHERE ccc > 432 ORDER BY ccc LIMIT 10 ⇒ INDEX(ccc)` – This "range" is compatible with ORDER BY

(It does not make much sense to have a LIMIT without an ORDER BY, so I do not discuss that case.)

Algorithm end

You have collected a few columns; put them in INDEX and ADD that to the table. That will often produce a “good” index for the SELECT you have. Below are some other suggestions that may be relevant.

An example of the Algorithm being ‘wrong’:

```
SELECT ... FROM t WHERE flag = true;
```

This would (according to the Algorithm) call for INDEX(flag). However, indexing a column that has two (or a small number of) values is almost always useless. This is called ‘low cardinality’. The Optimizer would prefer to do a table scan than to bounce between the index BTree and the data.

On the other hand, the Algorithm is ‘right’ with

```
SELECT ... FROM t WHERE flag = true AND date >= '2015-01-01';
```

That would call for a compound index starting with a flag: INDEX(flag, date). Such an index is likely to be very beneficial. And it is likely to be more beneficial than INDEX(date).
